HE BLOOD-BRAIN BARRIER IN INFECTIOUS DIAEASES

PERMEABILITY TO TOXINS IN RELATION TO THEIR ELECTRICAL CHARGES

BY ULRICH FRIEDEMANN, M.D. Berlin
TE DIRECTOR OF THE INFECTIOUS DISEASES DEPARTMENT,
RUDOLF VIRCHOW HOSPITAL, BERLIN; AND

A. ELKELES, M.D. Berlin.
LATE CHIEF ASSISTANT OF THE DEPARTMENT

108/2

1. Introduction: The Blood-brain Barrier

IN the pathogenesis of infectious diseases the ain is generally considered to be of outstanding portance. Symptoms characteristic of fevers, such apathy, insomnia, delirium, raised temperature, somotor collapse, and eventually death, are ascribed disturbances of the brain centres directly caused bacterial toxins (H. H. Meyer and Gottlieb,[1] olff-Eisner[2]). This opinion appeared to be fairly sonable as long as, according to Ehrlich, chemical inities alone were supposed to control the relations tween toxins and brain. Within the last few years, wever, investigators have become aware of the istence of a selective mechanism regulating the change of substances between blood and brain. is mechanism has been described as "barrière mato-encephalique" or "Bluthirnschranke." We pose to use the English equivalent and therefore ll speak of the blood-brain barrier or B.B.B. om all that is known about this barrier, and ecially from our previous work, it has become y doubtful whether this barrier is passed by ins. The investigation of this problem has been main object of the researches dealt with in the t part of this paper.

It should be emphasised that this problem does not ctly coincide with the question as to whether ins act on the brain, however closely both questions y be connected with one another. Tetanus in, for instance, does not pass the B.B.B., but s on the brain and the spinal cord. On the other d, non-susceptibility of the brain to toxins does necessarily imply impermeability of the B.B.B. the same toxins, because it may well be explained lack of affinity to brain cells. This discrimination y appear somewhat irrelevant from the point view of pathogenesis, but it is of great importance m its bearing on methods of investigation. Moreer, it is indispensable for the second part of the sent paper, where the ability of toxins to pass the B.B. will be dealt with in connexion with their ysico-chemical properties.

The methods available for the investigation of selective mechanism of the B.B.B. have been cribed in a series of previous papers. Their plication to the investigation of toxins and some difications especially devised for this purpose will discussed below. The experiments now described e largely confined to cobra venom and lambsentery toxin, and a few have been made on tulinus toxin. In previous papers experiments diphtheria toxin have been recorded. To arrive more general conclusions it was necessary to clude all information on the subject available from literature. As a matter of fact the problem we dealing with has hardly been ever discussed to now, and the recorded experimental data have been largely misinterpreted. They are invaluable, however, when their real significance is recognised. The explanations we shall give of them are based on our previous experiments on the B.B.B. and differ considerably from those given by previous workers on toxins. A critical re-examination of the facts already recorded from this new aspect has therefore been an essential part of our work.

2. The Methods of Investigation of the B.B.B.

At the beginning of our experimental work no methods were available for the investigation of the selective mechanism of the B.B.B. The only method largely used by clinicians was the identification in the cerebro-spinal fluid of substances previously introduced into the body. This method was, however, based on completely erroneous conceptions of the localisation of the B.B.B.

According to Goldmann[3] and Lina Stern,[4] the B.B.B. was identified with the "Blutliquorschranke," the barrier localised in the choroid plexus and in the meningeal vessels; and substances circulating in the blood were supposed to reach the brain exclusively by way of the cerebro-spinal fluid. Walter[5] has shown, however, that this theory is incompatible with modern conceptions of brain metabolism. The oxygen consumption of the brain is now known to be very high, and the material necessary for combustion cannot be supplied by a fluid almost completely destitute of foodstuffs. The crucial experiments to refute Lina Stern's theory were carried out by Wesselkin,[6] Friedemann and Elkeles,[7] and Schmid[8] independently of one another. Friedemann and Elkeles found that alizarin blue and some basic aniline dyes, when injected intravenously, stain the brain but leave the cerebro-spinal fluid entirely uncoloured.

In accordance with Walter and Spatz we have come to the conclusion that, as regards the exchange of substances between blood and tissues, the brain does not materially differ from other organs. The selective mechanism of the B.B.B. is localised in the walls of the cerebral capillaries and coincides with the permeability of these vessels.

This result is fundamental to all methods described in the present paper. According to the character of the individual toxins a variety of methods has been devised. In some cases reliable results were obtained, only by the combined application of several methods. The individual methods will be described in detail in the following sections, but some general remarks may be made here. Action on the brain may generally be taken as indicating permeability of the B.B.B., unless there is some specific evidence to the contrary, as, for instance, in the case of tetanus toxin which will be discussed later, and can be demonstrated by physiological, pharmacological, and some other methods. On the other hand, permeability of the B.B.B. to toxins can be investigated independently of their action on the brain. For this purpose, after intravenous injection of the toxin, pieces of the brain emulsified in saline are introduced into other animals. Finally, action on the brain and permeability of the B.B.B. can be tested simultaneously by applying the methods of artificial perfusion of the brain, and of the auxoneurotropic effect. The combined application of several methods is necessary in those cases in which, under ordinary experimental conditions, the toxin has been shown to have no effect on the brain. In these cases the impermeability of the B.B.B. can be demonstrated in the following ways. Either the toxin can be shown to be effective when the B.B.B. is circumvented, or the absence of the toxin from the brain after its intravenous injection

O

can be demonstrated by the method described above. Only in the light of these fundamental considerations can facts recorded in the literature, as well as our own experiments, be interpreted accurately. The lack of a clear understanding of methods will be found to be responsible for the misinterpretations with which we shall meet in reassessing the significance of recorded facts. After these general remarks we now proceed to a more detailed discussion of the individual toxins.

3. Permeability of the B.B.B. to Toxins

UNIDENTIFIED TOXINS OR ENDOTOXINS CAUSING GENERAL FEVER SYMPTOMS

Bacterial toxins prepared in artificial media and studied experimentally are few in number. Yet the opinion is prevalent that symptoms common to all fevers such as raised temperatures, apathy, insomnia, delirium, and metabolic disturbances are directly caused by toxic substances of bacterial origin. Although no experimental evidence whatsoever is available to support this opinion, yet it is chiefly responsible for the general conception that toxins act on the brain. *As a matter of fact clinical observations* are very unreliable in ascertaining the cerebral origin of pathological disturbances. The brain centres regulating temperature, blood pressure, and metabolism control very complicated peripheral mechanisms, and the conception that disturbances in the functions controlled by these centres are caused by lesions of the centres themselves is largely hypothetical. Cramer,[9] for instance, pointed out that in the production of fever the thyroid gland and the suprarenals have an important part. As a rule, it is also not sufficiently realised that infection produces a series of severe changes in metabolism and in the physical condition of the body which may lead to cerebral symptoms. There are some experimental indications that raised temperature in fevers may be partially due to these secondary conditions. When fresh guinea-pig serum is incubated with dead bacteria or with agar (Bordet[10]) or starch (Nathan[11]) it acquires pyrogenic properties (Friedberger and Mita[12]). These observations strongly suggest that, under the influence of infection, pyrogenic substances are produced in the blood and in the tissues. On the other hand, there are indications that raised temperature or metabolic processes connected with it may produce cerebral symptoms characteristic of infectious fevers. We cannot but accept this explanation for the well-known fact that in typhoid fever pyramidon frequently removes all these symptons, although it certainly does not neutralise toxins.

This is all we know of these unidentified toxins. We emphasise the fact that common fever symptoms have not been proved as yet to be directly caused by the action of bacterial toxins on brain centres. No evidence whatsoever is available as regards the question whether or not these toxins pass the B.B.B.

DIPHTHERIA TOXIN

Of all toxins diphtheria toxin has been most thoroughly investigated. Meyer and Gottlieb merely express the current opinion in saying that death in diphtheria is due to poisoning of brain centres. From a clinical point of view this assertion, however, is not convincing. In diphtheria, in particular, cerebral symptoms characteristic of other febrile diseases such as apathy, insomnia, and delirium, are not observed. Fever is frequently absent in the most severe cases, and the respiratory centre is hardly ever involved.

The opinion of Meyer and Gottlieb is [illegible]er the the conception of Romberg and Pässler [illegible] death i diphtheria is due to failure of the vasomo or centre. Th conception, however, although nearl unanimousl accepted, cannot be maintained any lon er. Vasomot collapse, indeed, has been shown by MacCallum[14] to b an outstanding factor in diphtheria poisoning. But Porte and Pratt[15] found that the vasomotor centre *is not at a* impaired in experimental diphtheria, *not even in the fina* stages of the disease. To us these two facts can b explained only under the assumption that vasomoto *collapse in diphtheria is of peripheral origin* and canno be regarded as a proof for the cerebral action of diphtheri toxin.

Caporali[16] and Speransky[17] claimed to have prove by indirect methods that death in diphtheria is brough about by an action of the toxin on the brain. Caporal injected rabbits intravenously with diphtheria toxin an compared the effects of *antitoxin by the intracerebra* and the intravenous route. He found that antitoxi was more effective when given intracerebrally. Speransk stated that in rabbits the power of antitoxin is enhance by repeated withdrawal and reinjection of cerebro-spina fluid, a process by which, he claimed, an increased permeability of the choroid plexus is induced. If thes experimental results are accepted, it must be regarded a demonstrated that diphtheria toxin has a direct actio on the brain. Friedemann and Elkeles,[18] however, in large series of experiments, failed to confirm the result of Caporali and Speransky.

Another series of Caporali's experiments are ver instructive in that they show that a misinterpretation o the experimental evidence becomes inevitable when th *mechanism of the B.B.B. is ignored. Caporali claimed t* have demonstrated the importance of the brain in th pathogenesis of diphtheria by the fact that diphtheri toxin when injected intracerebrally is 10 to 20 time more effective than by the intravenous route. This fact however, although confirmed by Friedemann and Elkeles only reveals the high toxicity of diphtheria toxin to brain cells when the B.B.B. is circumvented. It does not imply that diphtheria toxin has any effect on the brain when introduced in the ordinary way. But the affinity of diphtheria toxin to brain cells demonstrated by Caporali's experiments clearly shows that the inactivity of diphtheria toxin on brain, demonstrated by Porter's and Pratt's experiments, can only be explained by the impermeability of the B.B.B. to the toxin. The correctness of thi *explanation is shown by the following experiments* which again were not interpreted in this way at the time when they were carried out.

As early as 1898 Roux and Borrel[19] have found that diphtheria toxin is almost innocuous to the rat when given by the ordinary routes. Injected intracerebrally, however, it proved to be as toxic as in the most susceptible animals. From our point of view the experiment can be explained only by the assumption that, at least in the rat, the B.B.B. is completely impermeable to diphtheria toxin.

Final proof for this conclusion can be found in the experiments of Bieling and Gottschalk,[20] who tried to identify diphtheria toxin in the various organs of animals which had received toxin intravenously. They succeeded in finding it in most organs, but they entirely failed to find it in the brain. These experiments were repeated by Friedemann and Elkeles[18] with exceedingly high amounts of toxin, and with identical results.

When all the experimental evidence is taken together it is clear that, contrary to an opinion hitherto believed to be well founded, diphtheria toxin does not act on the brain in the acute stage of the disease, because it cannot pass the B.B.B.

The opinion that diphtheria toxin is poisonous to the central nervous system was also suggested by the appearance of paralysis in the late stages of the disease. In a very careful histological study Pie ro Uhry[21] recently arrived at the conclusion that lesions are only found in the peripheral nerves. We think that this result presents a satisfactory explanation for the complete curability of post-diphtheric paralysis. In poliomyelitis, where the cells of the brain and the s hat, rd degenerate and die, permanent paralysis, is a ule, remains after the disease itself has subsided.

BOTULINUS TOXIN

Another toxin which is generally regarded as a specific toxin for the central nervous system is botulinus toxin. This opinion was even held by Forssman[22] although his experiments, in our opinion, prove exactly the reverse. While Kempner and Pollak,[23] Ossipoff,[24] and Römer and Stein[25] believe that they have found definite histological changes in the ganglion cells of the brain and of the spinal cord, Dickson and Shevky, in a very careful investigation, completely fail to confirm these results. As an outcome of their own experiments they conclude that botulinus toxin acts on the peripheral nerves. They found that in the parasympathetic nervous system the conduction of the nerve impulses is blocked by the toxin. The motor nerves were shown to have become susceptible to abnormally rapid fatigue on faradic irritation.

The most striking proof for the peripheral action of botulinus toxin, at least as we see it, was afforded by Forssman's experiments. No increased toxicity was observed when the toxin was introduced intracerebrally. Moreover, under these conditions, the toxin was easily neutralised by antitoxin given in the ordinary way. From all we know, these results are completely incompatible with the assumption that botulinus toxin has any specific affinity for brain cells. On the other hand, a special effect of the toxin on the action of the diaphragm could be demonstrated. The lethal dose was considerably reduced when the toxin was introduced into the lungs, the pleural or the peritoneal cavity, and under these conditions the diaphragm was paralysed. Antitoxin was ineffective as soon as symptoms had appeared.

Keeping in mind the lack of affinity of the toxin for brain cells, made evident by the above experiments, we could not expect an effect on the brain, even when the B.B.B. was permeable to the toxin. It was necessary, therefore, to investigate this question separately, by a method independent of the affinity of the toxin for brain cells.

With this object the following experiments were carried out.

Botulinus toxin A, which was kindly placed at our disposal by Prof. H. Schmidt, Marburg, and of which 0·00005 c.cm. injected intraperitoneally killed mice within 48 hours, was injected intravenously into mice. 0·1 c.cm. was used. After one hour the mice were killed and the toxin contents of brain and blood were compared. The results were not quite consistent. In the majority of the experiments the brain was completely free from toxin. In one experiment some toxin was found in the brain. But the amount was so insignificant, as compared with that of the blood, that we are inclined to ascribe it to the blood content of the brain. As a characteristic example the following experiment is described in detail.

A mouse of 20 g. had 0·1 c.cm. botulinus toxin A injected intravenously. The mouse was killed after one hour and the brain (400 mg.) ground in 1 c.cm. saline. 0·25 c.cm. of this emulsion injected intraperitoneally into a mouse of 20 g. was innocuous. 0·0001 c.cm. blood, also injected intraperitoneally, killed the mouse within 24 hours.

This experiment shows conclusively that the B.B.B. is impermeable to botulinus toxin.

TETANUS TOXIN

In a number of ways and by a number of investigators tetanus toxin has been conclusively proved to act upon the central nervous system, but it was early realised that tetanus toxin does not pass directly from the blood to the spinal cord; it reaches the central nervous system by way of the peripheral nerves. Two fundamental facts are the basis of this conception. First, the orderly inter-relation between the length of the incubation in the individual species and their relative size. Secondly, the beginning of symptoms in the site where the toxin has been injected. Moreover, Meyer and Ransom[27] could directly identify in the sciatic nerve the toxin previously injected subcutaneously into the hind leg of a cat. In this way they clearly demonstrated the wandering of the toxin in the peripheral nerves. Another set of ingenious experiments were carried out by Meyer and Ransom to the same purpose. They are not, however, dealt with in detail, because they have considerably lost in credit, since Horster and Whitman[28] have shown, in experiments with dyes, that toxin and antitoxin injected into the sciatic nerve apparently reach the spinal cord at once. There remains, however, sufficient evidence for the conception that the toxin reaches the spinal cord and the brain exclusively by way of the peripheral nerves. In our opinion this fact can only be explained by the assumption that the B.B.B. is completely impermeable to tetanus toxin.

THE TOXINS OF VIBRION NASIK AND VIBRION EL-TOR

In this and in the following sections a group of toxins will be considered which differ from the majority of toxins in the lack of an incubation period, and the rapidity of their action. We begin with the toxins of vibrion Nasik and vibrion El-Tor.

The mechanism of their action was carefully studied by Rothberger.[29] 3 to 5 c.cm. injected intravenously kill rabbits within two minutes. Injected in smaller doses they produce characteristic symptoms of dyspnœa. Rothberger attributes, however, no significance to these symptoms, on account of the fact that artificial respiration did not prevent or even delay death. He ascribes death to heart failure, demonstrated in the isolated heart of the cat, and feels entitled to deny any action of the toxins on the brain. In our opinion this conclusion is not warranted. The symptoms of dyspnœa observed by Rothberger seem to indicate that, in addition to heart failure, the respiratory centre is severely poisoned.

Unfortunately we have had no opportunity to apply the methods described below to the toxins of vibrion Nasik and vibrion El-Tor. The question whether they pass the B.B.B. therefore remains open, but we are rather inclined to answer it in the affirmative.

LAMB DYSENTERY TOXIN

The lamb dysentery bacillus was isolated by Gaiger and Dalling[30] in O'Brien's laboratory during an epidemic in newly born lambs. It is an anaerobic micro-organism of the perfringens group. The toxin was also discovered by Gaiger and Dalling, and a dried sample of it kindly placed at our disposal by Dr. O'Brien. It is a most powerful toxin which, injected intravenously, kills mice, guinea-pigs, and rabbits in doses of some miligrammes, and in a few minutes.

The toxins of other gas œdema bacilli resemble lamb-dysentery toxin in the rapidity of their action. The mechanism of this action was investigated by Miss Robertson[31] in the toxin of vibrion septique and by Straub[32] in the toxin of the "Gasbrand-bacillus of Ficker." Both authors demonstrated an acute action on the heart. As far as we are aware the mechanism of the action of lamb-dysentery toxin has not yet been investigated. We therefore record some interesting observations we met with in our experiments. There is a peculiar action on the heart. The auricles continue their activity after the ventricles have stopped beating. It would be interesting to find out whether this dissociation between auricles and ventricles is due to heart-block.

An action on peripheral nerves could be demonstrated in the following way. The sciatic nerves of a rabbit were exposed on both sides. On the right side the nerve was brushed with a solution of the toxin, on the left side with saline. Half an hour later a paralysis of the right leg set in and lasted for three days until death occurred. The left leg remained unaltered during the course of the experiment. The peripheral action of lamb-dysentery toxin is evident from this. Whether in addition to it the brain is involved was investigated by the following experiments.

The methods of the artificial perfusion of the brain and of the auxoneurotropic effect described below can be applied only *to toxins which exhibit an affinity* to brain cells. Before applying these complicated methods it appeared reasonable therefore to make sure that this condition was fulfilled. To this effect in a series of rabbits of 2500 g. the lethal dose of lamb-dysentery toxin was determined by the intravenous route, in another series by the intrathecal route.

TABLE I

Dose of lamb-dysentery toxin.	Rabbits which received the dose of toxin—	
	Intravenously.	Intrathecally.
100 mg. ..	+ 2 mins. after injection.	..
20 mg. ..	..	+ some hrs. after injection.
10 mg. ..	+ 5 mins. after injection.	+ some hrs. after injection.
5 mg. ..	+ 4 mins. after injection.	..
4 mg. ..	+ 5 mins. after injection.	..
2 mg. ..	+12 mins. after injection.	+ some hrs. after injection.
1 mg. ..	+27 mins. after injection.	+ some hrs. after injection.
1 mg. ..	Survived.	..
0·5 mg. ..	”	+ some hrs. after injection.
0·25 mg. ..	..	Survived.

It will be seen from these experiments (Table I.) that the lethal *dose in the intrathecal* is nearly four times lower than in the intravenous route. This result can only be explained by an affinity of lamb-dysentery toxin to brain cells. In spite of this increased toxicity the action is considerably delayed in the intrathecal route. Apparently diffusion through cerebral tissue is rather slow. Having demonstrated in this way the affinity of the toxin to brain, it was now necessary to determine whether the B.B.B. is permeable.

The method of the artificial perfusion of the brain was described by us in a previous paper.[33] It bears a close resemblance to the method of cross perfusion of the brain invented by Frédéricq[34] and Gaskell and Shore.[35] The brain of a rabbit, the receiver, is perfused by the blood of another rabbit,* the donor, by linking the carotids and jugular veins of both animals. The subclavian arteries of the receiver are ligatured near to their *origin*. Using alizarin blue as an indicator we were able to show that no perfusion at all is observed when the subclavian arteries are not ligatured. Blood clotting is prevented by the intravenous injection of heparin, generously placed at our disposal by the Schering A.G.

It is well known that in the dog the circulation of the brain cannot be completely separated from the general circulation on account of some anastomoses between the vertebral and the anterior spinal arteries.[36] But it is generally held that these anastomoses are insignificant in rabbits. This is, however, not quite true. In previous experiments we had pointed out indeed that alcohol, urethane, somnifen, and luminal natrium when injected into the femoral vein of the receiver left the brain entirely unaffected. Paraldehyde, however, under the same conditions abolished the brain reflexes of the receiver. The different action of the various narcotics is probably explained by a different action on blood-vessels, and consequently on the anastomoses between vertebral and anterior spinal arteries. Special stress is laid upon this observation, because it proved to be very helpful *in the* course of our experiments with lamb-dysentery toxin.

In the first series of experiments the toxin was injected into the brain circulation of the receiver. For this purpose some modifications of our original method were necessary. Obviously the donor would be killed, and the brain circulation immediately stopped, if the blood containing the toxin were allowed to return to the donor. The jugular veins of the receiver, therefore, were not linked with those of the donor. The blood was allowed to pour freely from the jugular veins of the receiver. To replace the loss of blood an appropriate amount of normal rabbit blood was intravenously introduced into the donor. The toxin was injected into the brain circulation of the receiver —i.e., into the carotids. Although a large series of experiments was carried out the results were unsatisfactory. In fact, the brain reflexes of the receiver (corneal, lip, tongue reflexes) disappeared *three to five minutes after* the injection of the toxin. But at the same time the brain circulation became insufficient. Apparently the blood-supply *to the* donor could not balance *long enough* the inevitable loss of blood.

In a second series of experiments the toxin was injected into the femoral vein of the receiver. The original method of perfusion was used. The peripheral action of the toxin was demonstrated clearly. The spinal reflexes disappeared, and the ventricles stopped beating. But, in the majority of experiments, the brain reflexes also disappeared three to five minutes after injection of the toxin, although the brain circulation was still excellent. Apparently the toxin reached the brain by way of the anastomoses between the vertebral and anterior spinal arteries. By these experiments the action of lamb-dysentery toxin on brain and the permeability of the B.B.B. to the toxin are clearly demonstrated.

These results are confirmed by the method of the auxoneurotropic effect. This phenomenon was described by us in a previous paper,[37] but as a method of testing the permeability of the B.B.B. it was used for the first time in these experiments. We found that the *permeability of the B.B.B. is considerably increased both by adrenaline* and pituitrin. This increase of permeability, however, is to some extent selective. It concerns exclusively those substances which normally pass the B.B.B. The efficiency of narcotic drugs and strychnine was increased to from five to ten times its normal value on account of the increased permeability of the cerebral vessels. On the contrary the latter was found not to be increased for trypan-blue, salvarsan, and cobra antitoxin, which normally do not pass the B.B.B. The demonstration of the auxoneurotropic effect therefore indicates that the substance under investigation passes the B.B.B. and acts on the brain.

Using alizarin blue S as an indicator we could clearly demonstrate that the phenomena described above must be explained by an increased permeability of the cerebral vessels. To stain the brain definitely 10 to 15 c.cm. of a 5 per cent. solution of alizarin blue S must be introduced intravenously. When 2 to 3 c.cm. of adrenaline solution 1–10,000 are given previously, 2 c.cm. of the same alizarin blue solution effect an intense staining of the brain, the lungs, and the heart. Obviously the permeability of the vascular system is increased in all those areas which do not participate in the general vasoconstriction produced by adrenaline. This suggests that the phenomenon is due, partly at any rate, to the rise in blood pressure. In the pulmonary vessels the increased permeability eventually results in lung œdema (Lusiada).[38] Pituitrin has an antagonistic effect on the pulmonary vessels. When adrenaline and pituitrin are given simultaneously, no lung œdema is observed and the lungs remain unstained. In a series of hitherto unpublished experiments we found that in this respect Hypophysine of the I.G. Farben A.G. (1 c.cm. = 3 international units) gave the best results. Pituitrin, Pitressin, and Pitocin of Parke Davis were far less effective. We have the impression that, apart from the vasopressin and the oxytocin, is a third component in the posterior lobe of the pituitary gland which specifically affects the pulmonary vessels. An action of pituitrin or hypophysine on the coronary arteries, suggested by some pharmacological observations, could not be clearly demonstrated as yet by the alizarin blue method. The cerebral vessels remain completely unaffected by pituitrin or hypophysine. The brain is even more intensely stained when hypophysine is added to adrenaline. We infer from these experiments that the combined application of adrenaline and hypophysine effects a fairly specific increase of the permeability of the cerebral vessels. In our experiments with lamb dysentery toxin 1 c.cm. hypophysine of the I.G. Farbenindustrie A.G. (1 c.cm. = 3 international units) was injected intravenously. One minute later 2–3 c.cm. adrenaline, 1–10,000, and immediately afterwards various doses of lamb-dysentery toxin were introduced, both of them intravenously.

---

* The experiments on cross-perfusion were all carried out at the Rudolf Virchow Krankenhaus, Berlin.

TABLE II

Dose of lamb-dysentery toxin.	Controls = rabbits which had received no hypophysine and no adrenaline.	Rabbits which had received 1·0 c.cm. hypophysine then 0·3 mg. adrenaline.
2·0 mg. ..	+ 10 mins. after injection.	..
1·0 mg. ..	+ 19 mins. after injection.	..
0·5 mg. ..	Survived.	+ 11 mins. after injection.
0·25 mg. ..	..	+ 24 hrs. after injection.

As a result of these experiments (Table II.) we found that by hypophysine and adrenaline the toxicity of lamb-dysentery toxin is considerably increased. It amounts to four times its original value. These experiments, as well as those in which the perfusion method was used, show conclusively that the B.B.B. is permeable to lamb-dysentery toxin.

COBRA VENOM

Cobra venom was chosen as a representative of animal toxins. The venoms of the crotalus group were inappropriate for our purpose on account of their hæmorrhagic components, which were expected to change the permeability of the B.B.B. We are deeply indebted to Dr. Th. Madsen, Copenhagen, for a large sample of dried cobra venom with which the following experiments were carried out.

A very careful investigation on the mechanism of cobra venom poisoning was made by Elliot.[39] A peripheral action of cobra venom was clearly demonstrated. Constriction of the arterioles of the frog's leg was produced by perfusing it with a 1 : 10,000,000 solution of the toxin. The hearts of frogs and mammals stopped beating when perfused with 1 : 500,000 solutions. Heart failure was prevalent in animals when large doses were given; but with small doses respiratory disturbances were observed. On account of these disturbances Elliot took the cerebral effect of cobra venom for granted. According to Arthus,[40] however, the nerve-endings in the diaphragm are paralysed by cobra venom.

In our own experiments the methods described in the preceding section were used. The results of the comparative intravenous and intrathecal injections are shown in Table III.

The intrathecal is at least ten times more effective than the intravenous injection. This means that cobra venom has a strong affinity to brain cells. Here again, as in the experiments with lamb-dysentery toxin, death was considerably delayed in the experiments with intrathecal injection on account of the slow diffusion of cobra venom through brain tissues. It is noteworthy that the results of the intravenous and intrathecal methods differ far more with cobra venom than with lamb dysentery toxin. Apparently cobra venom is more toxic to brain cells than lamb-dysentery toxin.

TABLE III

Dose of cobra venom.	Rabbits which received the dose of toxin—	
	Intravenously.	Intrathecally.
10 mg. ..	+ 3 mins. after injection.	..
5 mg. ..	+ 6–9	..
2·5 mg. ..	+ some hrs. after injection.	..
1·7 mg. ..	+	..
1·0 mg. ..	Survived.	+ 25 mins. after injection.
0·4 mg. ..	..	+ some hrs. after injection.
0·3 mg. ..	..	+
0·2 mg. ..	..	+

In applying the perfusion method we met with an unexpected complication. When cobra venom was injected into the brain circulation of the receiver the brain reflexes disappeared immediately and convulsions set in. But at the same time the outflow of blood from the jugular veins of the receiver stopped at once. This phenomenon is apparently due to constriction of the brain vessels. At least this explanation is suggested by Elliot's experiments. This vasoconstriction is the reason why the perfusion experiments gave no information on the permeability of the B.B.B. to cobra venom. When cobra venom was injected into the femoral vein of the receiver the spinal reflexes disappeared at once and the heart stopped beating. The peripheral action of cobra venom could be demonstrated, which has already been shown by Elliot with other methods. The brain reflexes remained uninfluenced for 20 minutes. Lamb-dysentery toxin and cobra venom differ from one another very much in the same way as has been described above for paraldehyde and the other narcotics. Apparently the anastomoses between the vertebral and anterior spinal arteries are constricted by cobra venom.

The *auxoneurotropic* effect on cobra venom is shown in Table IV. :—

TABLE IV

Dose of cobra venom.	Controls = rabbits which had received no hypophysine and no adrenaline.	Rabbits which had received 1·0 c.cm. hypophysine and 0·3 mg. adrenaline.
2·0 mg. ..	+ 5 mins. after injection.	..
1·0 mg. ..	+ 18	..
0·5 mg. ..	+ 40	..
0·1 mg. ..	..	+ 4 mins. after injection.
0·05 mg. ..	..	+ 10

The toxicity of cobra venom is increased to as much as 20 times its normal value by hypophysine and adrenaline. The permeability of the B.B.B. to cobra venom is made clear by these experiments. The auxoneurotropic effect is much stronger with cobra venom than with lamb-dysentery toxin. Evidently cobra venom is more toxic to the brain. The experiments therefore confirm the conclusion arrived at by a comparison of the intravenous and the intrathecal routes. As a whole, our experiments as well as those of Elliot suggest that the B.B.B. is permeable to cobra toxin.

4. Summary of the Preceding Investigations

We have thus reached a point at which, from experiments of our own and from a critical review of observations gathered from the literature, it can be stated that toxins differ among themselves in the facility with which they pass the blood-brain barrier. We can say that, of the seven toxins upon which information is available, two—viz., lamb-dysentery toxin and cobra venom—pass the B.B.B. The toxins of the vibrion Nasik and vibrion El-Tor are not yet sufficiently known in this respect. There are some indications that they too pass the B.B.B. Three toxins, those of tetanus, diphtheria, and botulinus, are definitely proved not to pass the B.B.B. There is another quality according to which the toxins under investigation fall into the same groups as according to their ability to pass the B.B.B. All toxins which were shown to pass the B.B.B. are characterised by the lack of an incubation period and the rapidity of their action. The toxins which do not pass follow the rule that the incubation period of toxins is commonly a long one. In the following section we shall record new facts which strongly suggest that this coincidence is more than accidental. If this is conclusively proved, it would mean that the majority of toxins do not pass the B.B.B. We still avoid, however, a generalisation like this. We are satisfied to point to the result that two toxins—viz., diphtheria and botulinus toxin—which hitherto have almost unanimously been believed to act on the brain, in reality have no effect on it. This is a most important result with regard to the pathogenesis of infectious diseases, and we shall have to refer to it again in the discussion.

(To be concluded)

THE TOXÆMIA OF ACUTE INTESTINAL OBSTRUCTION

THE VALUE OF B. WELCHII ANTITOXIN IN ITS TREATMENT

By Robert L. Holt, M.B. Manch., F.R.C.S. Eng.

ASSISTANT SURGEON TO THE CHRISTIE HOSPITAL, MANCHESTER;
ASSISTANT SURGICAL OFFICER, MANCHESTER
ROYAL INFIRMARY

It is doubtful whether any subject has attracted wider attention or resulted in more extensive investigation than has acute intestinal obstruction. The interesting and varied nature of the problem, together with the persistently high mortality resulting from the recognised lines of treatment, has provided a constant stimulus to research and a keen search for the so-called toxin of acute obstruction.

The existence of very toxic substances in the stagnant contents of obstructed loops of intestine was proved many years ago.[1] These substances when injected intravenously or intraperitoneally quickly cause death. Similar substances were shown later to be present in the contents of normal intestine,[2 3] especially after a protein meal.[4] It is well known that during normal digestion the intestinal mucosa displays a selective power in that substances of large molecular structure are not absorbed. Experiments by Wilkie [5] and others,[6 7] proving that the normal mucosa of the small intestine prevented the absorption of the products of intestinal putrefaction in appreciable quantity, dealt a severe blow to the generally accepted belief in the presence of a single lethal factor which accounted for death in all types of acute obstruction.

Hartwell and his co-workers[8] were the first to bring forward the theory that toxæmia in acute obstruction did not make its appearance in the presence of uninjured mucosa. They examined all the experimental data of Whipple and his associates and found that, in every case in which death supervened with obstruction or a closed loop, there were gross changes in the mucosa. Brooks[9] agreed with Hartwell that the toxæmia is directly proportional to the injury to the mucosa, and stated that the changes in the mucosa are caused largely by distension of the gut and the resulting embarrassment of the circulation. He added that there are two factors in the development of the toxæmia of obstruction, firstly the elaboration of the toxin, and secondly opportunities for the absorption of the toxin; and of these he believed the latter to be more important.

ELABORATION AND ABSORPTION OF THE TOXIN

The bacterial origin of the toxins in the content of obstructed bowel is now generally accepted. Those who tried to ascertain the rôle played by bacteria were faced with the almost insuperable difficulty of eliminating them entirely from segments of intestine. However, Dragstedt and his co-workers[10] isolated segments of intestine and left them open in the peritoneal cavity with all the nerves and vascular elements intact. At a later date another laparotomy was done and the loop contents found to be sterile. The ends of the loop were then inverted and the closed sterile loops returned to the abdomen. They found that animals so treated lived indefinitely, and furthermore they were able to strangulate these loops without any deleterious effect. Murphy and Brooks[11] carried out similar experiments and obtained the same results. The conclusion is that bacteria are necessary for the production of the toxin.

A toxæmia, that is to say a condition resulting from the absorption of toxic substances from the obstructed intestine, is not present in all cases of acute intestinal obstruction. It depends on the presence of a severely damaged mucosa in the obstructed segment. The importance of this factor of mucosal damage is evident in the recognition of three distinctive types of obstruction. These are :—

1. *Simple obstruction*, by which is meant an occlusion of the intestinal lumen not complicated by a circulatory disturbance of the obstructed segment of intestine.

2. *Acute strangulation*, in which the obstructing mechanism interferes grossly with the circulation of the obstructed loop, usually affecting the vessels in the mesentery.

3. *Distension necrosis*, in which the progressive distension of the obstructed segment (whether open or closed) interferes with the circulation of the intestinal wall and produces patchy gangrene of the mucosa.

In simple obstruction the excessive vomiting, which is such a marked feature of these cases, results in a progressive dehydration and sodium chloride loss with ultimate death. The most persuasive evidence that dehydration can be a directly fatal condition is the fact that death can be prevented and symptoms removed if the dehydration is adequately repaired by the subcutaneous or intravenous administration of sufficient quantities of the lost material in the form of a physiological sodium chloride solution. Gamble and his co-workers [12] state that this simple explanation is sufficiently indicated by the data at hand to make unnecessary the hypothesis of a toxin absorbed from the gastro-intestinal tract.

The other two conditions present a very different pathology. In acute strangulation, as it is seen clinically, the veins draining the loop are obstructed and the arteries remain patent, with the result that the loop becomes increasingly distended with blood until thrombosis closes the smaller arteries. Under such conditions the cause of death depends on the length of bowel involved.[13] When long loops (two feet or more) are affected, sufficient blood is withheld from the circulation by the loop to produce an acute circulatory collapse and death. Moderate-sized loops (one to two feet) are unable to hold up sufficient blood in this manner, and in these cases it has been shown that death is due to the absorption from the peritoneal cavity of the fluid exuding from the loop. This fluid is at first indistinguishable from blood plasma, but about 16 hours after the onset it begins to contain toxic substances in increasing quantity which result from the action of bacteria on the disintegrating tissues of the intestinal wall. When short loops (less than one foot) are strangulated, the process goes a step further and death is preceded by a perforation of the loop which floods the peritoneum with a toxic fluid which is also swarming with bacteria, and death results from a combination of toxæmia and peritonitis.

Distension necrosis is always the result of delay in relieving the obstruction. Most cases begin either as a simple obstruction or as an obstructed loop in which primarily there is no interference with the circulation of the obstructed intestine. As a result of delay in treatment, and aggravated by the use of purgatives and the taking of drinks, the intestine becomes progressively distended. The effect of such distension is most marked in that portion of the bowel furthest removed from its mesentery, and capillary rupture with submucous hæmorrhages results.[14] The mucosa is damaged and the contents of the intestinal lumen come into direct contact with the unprotected tissues of the intestinal wall and death may follow from the absorption of toxic substances from the lumen. But while these changes are taking place the patient is frequently vomiting and the resulting dehydration may become a serious factor. In this way distension necrosis combines the features of simple obstruction and strangulation.

Toxæmia therefore only occurs in those cases of acute obstruction where the wall has been sufficiently damaged to allow of abnormal absorption, and this factor, rather than the mere presence of the toxins in the lumen, is evidently the dominant one. The exact nature of the toxin of acute intestinal obstruction is unknown, and this adds to the experimental difficulties experienced in producing evidence of the absorption of a toxin from the obstructed intestine. In acute strangulation it has been conclusively shown that the prevention of absorption via the peritoneal cavity by enclosing the strangulated loop in a rubber bag will materially prolong the life of animals.[13] The direct evidence of the presence of a toxin in the blood of animals dying of distension necrosis is very scanty. Sugito [15] aspirated blood from the veins in the mesentery of an obstructed loop and found that the serum obtained from this blood was toxic to mice, and although Scholefield [16] corroborated these observations he emphasised the fact that the blood must be obtained during the last few moments of life to show toxicity. In consequence of the difficulty of obtaining direct evidence of the absorption of toxins from obstructed loops, the problem has been studied by indirect methods. One of the most important of these has been the study of the part played by the *Bacillus welchii* in the pathology of acute intestinal obstruction.

THE B. WELCHII THEORY

The nature of the bacteria responsible for the elaboration of the toxin did not arouse great attention until the publication in 1926 of a paper by Williams,[17] who advanced the hypothesis that the toxæmia of acute obstruction was due at least in part to the absorption of the toxin of *B. welchii* from the obstructed bowel. He noted the marked resemblance of the terminal stages of the toxæmia of gas gangrene to that of acute obstruction. He observed that *B. welchii* was by far the commonest anaerobe in the intestinal tract, and he isolated it from the vomitus and intestinal content after obstruction in a high percentage of cases of ileus. On the basis of this theory he gave *B. welchii* antitoxin to patients suffering from intestinal obstruction or peritonitis with an apparently favourable effect upon the mortality-rate. The suggestion that the toxæmia of acute intestinal obstruction is due to a known bacterial toxin aroused considerable interest, especially since the effects of the toxin suggested could be counteracted by a specific antitoxin. Numerous papers on the subject have since been published and I shall summarise them briefly.

Morton and Stabins [18] found that in dogs the development of the toxæmia following obstruction in the jejunum seemed to be delayed by the administration of the antitoxin, and the mortality was lower in an mals given the antitoxin before operative relief. Owings and McIntosh [19] concluded that the life of dogs with high intestinal obstruction was not prolonged by the use of *B. welchii* antitoxin. It is unfortunate that these experiments have dealt with high obstruction only, in which there is no evidence to show that a toxæmia ever exists. In these cases the main lethal factor is dehydration and not toxæmia, and therefore the value of *B. welchii* antitoxin cannot be decided on such experiments.

The number of workers who have studied the value of *B. welchii* antitoxin in the type of case in which toxæmia is known to exist is not very large. In 1929 McIver, White, and Lawson[20] selected for their experiments a closed loop of bowel, the veins of which were ligated, producing an acute strangulation. They gave their reasons for choosing this type of obstruction as follows. Firstly, death is known to be due to a toxæmia; secondly, death occurs before water and chloride loss can affect the issue; and thirdly, the conditions existing in a strangulated loop have been shown to be ideal for the growth of anaerobic bacteria. The experiment was therefore well planned but they were unable to show that the administration of *B. welchii* antitoxin prolonged the life of their animals. The only criticism which may be levelled at their experiments is that they were putting *B. welchii* antitoxin to the severest possible test. Perforation of a strangulated loop and flooding of the peritoneum with a highly toxic and infected fluid is the rule about 24 hours after the onset of strangulation. It is unlikely that any systemic treatment can affect the issue in such cases.

Copher, Stone, and Hildreth[21] utilised an isolated closed loop of jejunum and stated that the administration of *B. welchii* antitoxin on the day of operation prolonged the lives of their animals. Thurston[22] carried out a similar series. He stated that:

> The production of a closed loop is a questionable procedure because rupture of the loop with peritonitis is so commonly found after death, to which, of course, no immunity is possible. If the loop is found intact and no other cause for death is found, it is reasonable to assume that absorption of some of the lethal bodies within the loop has caused death. In animals with unruptured loops and without simple obstruction the administration of the specific antitoxin should have prolonged life if the absorption of that particular toxin is the cause of death.

He concluded from his experiments that the *B. welchii* antitoxin had neither a prophylactic nor a therapeutic value.

The ideal case in which to test the value of *B. welchii* antitoxin is undoubtedly an obstruction situated in the lower ileum or colon. Such cases usually terminate in the condition described as distension necrosis, and death is due to the absorption of a toxin from the obstructed segment. There is no complicating peritonitis, and if *B. welchii* toxin plays any part in the toxæmia of acute obstruction it is in this type of case that the antitoxin should prove its value. These cases present the added attraction of occurring very frequently in clinical practice. North[23] selected an obstruction of the terminal ileum for his experiments. He stated that the use of *B. welchii* both intravenously and enterally does not provide any evidence that it exerts a deterrent influence upon toxæmia or prolongs life following the production of a low intestinal obstruction closely simulating that encountered by the surgeon. He added that giving the antitoxin in a single dose at the time of operation, as he did, might not render it available at the time it was most needed. When discussing low obstruction in dogs, he stated that the changes in the blood chemistry are inconspicuous and that vomiting does not occur. He accordingly did not administer sodium chloride solutions to his animals after operation.

With these views I cannot agree. The loss of water and electrolytes by vomiting in cases of low obstruction is much less rapid than in high obstruction, but there is no doubt that, in any series of dogs with a low obstruction, a definite percentage will die as a result of dehydration and chloride loss. This percentage is increased by allowing the animals water to drink post-operatively.[24] It would appear therefore that, in order to estimate the value of *B. welchii* antitoxin in cases of low obstruction, it is essential that any possible degree of dehydration should be controlled by an adequate replacement of sodium chloride solution. The following series of experiments was carried out with that object in view.

EXPERIMENTS

Eleven dogs in all were used. An identical technique was adopted in each case. The dogs were given gr. ¼ morphine half an hour before operation, which was conducted under ether anæsthesia. The ileum was divided about six to ten inches from the cæcum and the two ends closed and invaginated. A careful asepsis was maintained throughout the operative procedure. After operation the dogs were allowed to drink water as required. Food was not given. Most of the animals vomited the day after operation and the vomiting in small amount continued until the experiment was concluded. It was noted that, after the second or third day, very little water was drunk, although it was always available. All the dogs were given intraperitoneal injections of 1 per cent. sodium chloride solution daily to counteract the dehydration which resulted from the vomiting. At first 250 c.cm. per day was regarded as sufficient but one dog died on the third day after operation from what I thought was dehydration. The dosage was accordingly increased to 750 c.cm., with marked improvement in the animals' condition. Six of the dogs were given at intervals injections of *B. welchii* antitoxin. The concentrated serum—5 units per c.cm.—was used, and each animal received a minimum dosage of 15 units per kg. of body-weight, three times the dose recommended by Williams.[17] The injections were commenced the day after operation and were continued on alternate days. Blood samples were taken at times indicated in the accompanying Table and estimations of the chloride level and non-protein nitrogen (N.P.N.) fractions made. In order to simplify the results and the subsequent comments I have tabulated the order of events as though all the operations were performed on the same day.

Estimations of Non-protein Nitrogen and Chloride in Animals, with Experimental Intestinal Obstruction

The *B. welchii* antitoxin was given by intramuscular injection to dogs 1–6 in the Table. In considering the results of this series I wish to eliminate dogs 3 and 11. The former died from a widespread peritonitis which probably followed a leakage at one of the suture lines. The latter apparently died from dehydration and sodium chloride loss. In all the remaining animals the autopsy findings were identical, differing only in the degree of distension of the obstructed intestine. The closure of the ends of the intestine was sound and there was no evidence of peritonitis. The portion of intestine immediately proximal to the obstruction was distended to several times its normal size, and the walls were very œdematous and congested. Striking changes were found in the intestinal mucosa. Numerous reddish-coloured areas were evident; the mucosa had been completely shed, and scattered submucous hæmorrhages were sometimes noticeable. These changes were most marked in the two feet of intestine proximal to the obstruction and were seldom evident beyond that distance. The liver was very small and showed marked evidence of fatty degeneration, but this was to be expected as a result of the period of starvation through which the dogs had passed.

It will be seen that the dogs receiving injections of *B. welchii* antitoxin fared no better than the untreated controls. Five dogs receiving the antitoxin lived a total of 63 days, or an average of 12·2, whilst four dogs not receiving the antitoxin lived 51 days, an average of 12·75. The results are fairly even and are not unduly affected by the result of one particular experiment. The chemical estimations on the blood samples are interesting. It appears that the administration of adequate amounts of sodium chloride solution prevents an increase in the concentration of the nitrogenous elements in the blood. Estimations made just before death show no rise in the N.P.N. fraction beyond normal limits. It is probable that the rise in the N.P.N. fraction so frequently noticed in experimental results is dependent upon impairment of renal function owing to dehydration. There is no evidence to associate a rise in the N.P.N. of the blood with the toxæmia of intestinal obstruction. From these experiments it is safe to conclude: (1) that animals with an obstruction in the terminal ileum die in spite of the prevention of dehydration and chloride loss; and (2) that life is not prolonged in these cases by the administration of large doses of *B. welchii* antitoxin.

The results of many other investigations into the problem of the toxæmia of acute intestinal obstruction are no more helpful to the *B. welchii* theory. There is ample evidence that anaerobic, sporulating, gas-forming organisms of the *B. perfringens* group are frequent inhabitants of the terminal ileum and there is no doubt that they proliferate in the lumen of the bowel after obstruction.[17 20 22] The cultural studies of the bacterial flora of obstructed loops carried out by McIver and his associates [20] deserve careful consideration. They found that there was no noteworthy increase of any organisms of the aerobic group but that the numbers of the *B. welchii* group were always increased and in no case was there any doubt that *B. welchii* was the predominant organism. They drew attention to the fact that different strains of *B. welchii* show marked variations in their ability to produce toxin, and proceeded to determine the variations in the organisms isolated from obstructed loops. Fourteen strains were used and of these eight were entirely devoid of demonstrable toxicity. Only two strains developed a toxin which compared favourably with that elaborated by a strong toxin-producing stock strain. The hæmolytic power of the *B. welchii* toxin is well known, and animals dying as a result of a lethal dose of toxin show at autopsy evidence of a definite hæmolysis with bloody fluid in the chest and abdominal cavities. But Owings and McIntosh [19] bring out in their paper the evidence that the hæmolysis that follows the intravenous injection of a lethal dose of loop toxin is very much less than that resulting from an injection of *B. welchii* toxin. They show that immunity to the *B. welchii* toxin affords no protection against an injection of the loop toxin, and point out that animals may be successfully immunised against *B. welchii* toxin. These findings have been confirmed by Thurston.[22] Dragstedt [25] was unable to demonstrate the development of any immunity in animals subjected to injections of sublethal doses of the loop toxin. Furthermore, the substance is not destroyed by boiling[26]; it is held up by a Berkefeld filter [27] and it is precipitated by five volumes of alcohol.[28] The striking similarity between the pharmacological actions of the toxic substance and those of the proteoses has been mentioned by Whipple [29] and Chittenden.[30] Thus, while there is still considerable doubt as to the exact nature of the toxic substance present in obstructed loops of intestine, the bulk of evidence is not in favour of its being a bacterial exotoxin.

CONCLUSION

B. welchii is the predominant organism present in obstructed or strangulated loops of intestine. The suggestion that the absorption from the obstructed bowel of the exotoxin of *B. welchii* is responsible for the toxæmia of acute intestinal obstruction is not borne out by later experimental work. It is important to observe that some of the earlier work which appeared to support the *B. welchii* theory was the result of experimental obstruction of a type in which toxæmia is not a lethal factor. There has now accumulated a sufficient amount of evidence from types of cases in which death is usually due to a toxæmia to suggest that the *B. welchii* toxin does not play an important rôle in acute intestinal obstruction. It is only fair to state that, on the clinical side, Williams [17] and Bower and Clark [31] have felt that improvement followed the use of *B. welchii* antitoxin in the treatment of their cases of acute obstruction. But before this opinion can be established it will be necessary to bring forward a series of carefully controlled cases with a type of intestinal obstruction in which death results from toxæmia. The mere presence of *B. welchii* in large numbers in the obstructed segment of intestine by no means proves that it is a factor of importance in producing the symptoms of the disease. Cultures of the organism from cases of acute obstruction show a large number of avirulent strains, a feature which appears to be characteristic of the strains of *B. welchii* isolated from the fæces or from wounds of the perineum and adjacent localities, where the organisms produce little or no toxin and cause no clinical symptoms of infection. But the part played by *B. welchii* in the pathology of acute intestinal obstruction cannot be summarily dismissed. Its proteolytic power is probably of great importance in the production of the toxin of acute obstruction if the view is accepted that the toxin is probably a proteose and its gas-producing power is partly responsible for the marked distension of the obstructed segment which precedes any absorption of the toxin. In this way it is probable that *B. welchii* plays an important part in the development of the toxæmia of acute obstruction. But the experimental evidence does not support the view that the exotoxin of *B. welchii* plays any part in the toxæmia of acute obstruction, and the use of the antitoxin has not proved of any value in the treatment of those types of acute obstruction in which a toxæmia is believed to exist.

The experimental work mentioned in this paper was carried out at the Johns Hopkins medical school, Baltimore, U.S.A., under the direction of Prof. Dean Lewis during the tenure of the Dickinson travelling scholarship in medicine.

THE TREATMENT OF TETANY

BY I. SNAPPER, M.D.

PROFESSOR OF MEDICINE AND GENERAL PATHOLOGY IN THE UNIVERSITY OF AMSTERDAM

THE so-called carpo-pedal spasms characteristic of tetany consist in flexion of the metacarpo-phalangeal joints with extension of the other phalangeal joints and opposition of the thumb. The resulting position is called, for obvious reasons, "main obstétricale." Similar contractions occur in the foot and there is often simultaneous spasm of the facial muscles and chest. Severe attacks may be complicated by epileptiform cramps.

Tetany may, however, be present when no carpo-pedal spasms are seen. The existence of this "latent tetany" is indicated by—

1. *Chvostek's sign.*—Percussion of the cheek just in front of the external auditory meatus causes contraction of the facial muscles.
2. *Trousseau's sign.*—A typical carpal spasm appears when the upper arm is compressed for a minute or two.
3. *Erb's sign.*—Electrical stimulation of the nerves of the arm reveals an increased and abnormal irritability of the peripheral nervous system.
4. *Schlesinger's sign.*—A typical pedal spasm is produced by flexing the hip-joint with the knee extended, the patient being recumbent.
5. *All patients with tetany have a tendency to develop* cataract and trophic disturbances of the nails and teeth.

Manifest and latent tetany have one general cause—hypocalcæmia. When the *calcium content of the* blood-serum falls below 7 mg. per 100 c.cm. symptoms of tetany usually appear. *Hypocalcæmia can be produced by various causes but this paper deals with* two kinds only—namely, lesions of the parathyroid (*parathyroprive tetany*); and idiopathic—apparently causeless—tetany in which the function of the parathyroids is supposed to be diminished.

The prognosis of tetany has improved during the last decade, the treatment consisting in administration of calcium. Only a small part of any *calcium taken* by the mouth is absorbed from the intestine, and *intravenous injections*, though they can now be given without risk and almost always *cut short an acute* attack, have only a temporary beneficial effect. Vitamin D, when given with the calcium, improves *absorption* from the intestine. Subcutaneous injection of the active principle of the *parathyroid*, discovered by Collip in 1927 and marketed as Parathormone, causes a considerable increase in the blood calcium and will almost always counteract tetany. Only in very severe chronic cases do these three methods completely fail. Unfortunately *treatment* with parathormone is very expensive and its influence on hypocalcæmia *gradually* diminishes.

SURGICAL TREATMENT

Transplantation of parathyroid gland is usually ineffective; the transplant rarely survives, though temporary favourable results have been obtained, and the attacks of tetany generally recur after a few weeks or months. Gold[1] has recently reported one case in which parathyroid transplantation was successful.

CASE 1.—A woman was operated on for goitre in 1902. The operation was followed by a short period of tetanic symptoms, but these disappeared spontaneously and did not recur during subsequent pregnancies. Severe tetany, however, developed 13 years after the original operation. Transplants were made in 1920, 1921, and 1924, on each occasion being followed by temporary improvement. In 1930 the symptoms were serious, despite treatment by parathormone and calcium. In 1931 the attacks were accompanied by epileptiform convulsions, delirium, and dementia. Two more transplant operations were undertaken in March and April, 1931; the epileptiform cramps disappeared after the first, and the other symptoms after the second, and since then the patient has been able to go back to full work.

TABLE I

Serum calcium and inorganic phosphate in a case of parathyroprive tetany improved by transplantation of parathyroids (Gold).

	Serum Ca mg. per 100 c.cm.	Inorg. phosph. mg. per 100 c.cm.
Before transplantation	5·40	7·10
3 days after ,,	6·80	5·03
7 ,, ,, ,,	8·80	4·60
1 month ,, ,,	12·50	7·70
7 months ,, ,,	11·80	5·26
1 year ,, ,,	5·90	4·95
1½ years ,, ,,	8·20	5·70

The calcium content of the serum was less than 6 mg. per 100 c.cm. before the operation, and the inorganic phosphorus was very high: 7 mg. per 100 c.cm. instead of the normal 3·5 mg. (Table I.). After the 1931 operation the calcium became normal, and for a short time there was a slight but definite hypercalcæmia. The phosphorus reading, however, is still too high, indicating an incomplete function of the transplanted parathyroid. It is usual for the inorganic phosphorus to be high in idiopathic tetany and in tetany due to inadequate parathyroid function; there are, however, forms of tetany where both the calcium and the inorganic phosphorus are low—e.g., when fatty diarrhœa causes tetany.

In another case under my observation the transplantation of parathyroid saved the life of a patient with very severe tetany.

CASE 2.—A woman of 35 was operated on for goitre in 1915 and again for recurrence in 1924. Four days after the second operation typical tetany developed and was unaffected by very large doses of calcium lactate and parathyroid by the mouth. The attacks became more frequent and were soon accompanied by epileptiform convulsions. They were with difficulty controlled by the administration of 6 g. of chloral hydrate, and several injections of Pantopon daily. Dementia, complicated by attacks of delirium, developed, and this condition lasted for three months. At the end of that time Prof. Lanz transplanted two human parathyroids into the abdominal muscles. This operation immediately stopped the attacks, and the patient was able to go home after a period of convalescence.

Five years later she was examined again. She then felt completely well and took only calcium lactate and thyroid by the mouth. She had a severe attack of tetany in 1933 and came for examination a week later. Chvostek and Trousseau signs could not be evoked, but the calcium content of the serum was found to be 6·2 mg. per 100 c.cm. and the inorganic phosphorus 4·3 mg. The patient had previously been taking only one teaspoonful of calcium lactate; this dose was increased to two teaspoonfuls three times daily, together with two tablets of vitamin D. The symptoms disappeared completely. In September, 1933, the blood calcium was 8·07 mg. and the inorganic phosphorus 3·75.

In these two cases the benefits conferred by the transplantation of the parathyroids was lasting. Possibly in both one parathyroid gland was present but damaged, and was able to recover during the time when the transplant was being absorbed. Even so it would be remarkable that the attack should have lasted for more than three months and have become gradually worse in the presence of a damaged but recovering gland. It seems possible that the transplant may not have been absorbed, and it is at any rate certain that the operation saved the patient's life.

PARATHORMONE TREATMENT

Completely satisfactory results can also be obtained by continuous treatment with parathormone, as the following case shows.

CASE 3.—Another woman, aged 76, had typical carpopedal spasms in March, 1929, for the first time in her life. In May she had an attack of cardiac asthma and five days later a second attack of tetany. Two days later she suffered a third attack of tetany, and a week after that another attack of cardiac asthma. She was given calcium lactate, digitalis, and ouabaine by the mouth and improved somewhat, but during the succeeding summer she lost all her nails. In January, 1930, she developed cataract in both eyes and suffered from continual facial cramp when talking. Parathyroid tablets (by mouth) were started in June. In January, 1931, her condition was worse. She suffered from anorexia, stiffness in the fingers, cramps when talking, diminished eyesight, and crumbling nails. On May 6th, 1931, her blood calcium was only 4·9 mg. per 100 c.cm., although the inorganic phosphorus had not increased above 4·03 mg. (Table II.). Since then she has had 1 c.cm. of parathormone subcutaneously each day and her condition has improved from the first injection; the eyesight is better and the cramps have disappeared. After three weeks of parathormone treatment the blood calcium and phosphorus were normal and the dose was reduced to 1 c.cm. on alternate days. On June 25th she showed a slight hypercalcæmia and the dose was thereafter given every four days. After some trials a dose on alternate days was found to keep her blood calcium at the best level and this treatment has been continued up to the present. The patient feels well; she has no attacks of tetany and no heart trouble and her nails are normal. After a complicated cataract operation in 1933 she had a severe broncho-pneumonia from which she recovered.

TREATMENT BY A.T. 10

Some patients, however, cannot be kept in good health by any combination of surgical or medical methods. A new preparation has been discovered recently and has proved far more active than any of those previously used. Excessive doses of irradiated ergosterol may cause disagreeable or even dangerous symptoms which are usually accompanied by hypercalcæmia. Holtz,[2] working with Windaus in Göttingen, has made a study of the different fractions of irradiated ergosterol and has succeeded in isolating one portion which does not contain vitamin D but which has a specific influence on the calcium content of the serum. It is an oil-soluble fraction, standardised on mice, and known as A.T. 10. When taken by the mouth it causes hypercalcæmia in animals and men; the effect is less rapid than that produced by subcutaneous injection of parathormone but is more lasting. During the first few days after administration of A.T. 10 there is no considerable increase of blood calcium, but the dose should not therefore be increased, because if it is there will be accumulation and dangerous hypercalcæmia.

Holtz, in his investigations at the Charité Hospital in Berlin, has worked out the following treatment, which has proved reliable. In severe cases of tetany 5 to 10 c.cm. of A.T. 10 is given daily for three days. After this the dose must be considerably restricted, even if there is no increase in the blood calcium, lest hypercalcæmia and calcification of organs, especially the kidneys, results. Prolonged administration in correct dosage, however, is not dangerous. Holtz gave A.T. 10 to parathyroidectomised dogs for over a year and could find no symptoms of damage on autopsy.

I have tried A.T. 10 in three cases of tetany, one idiopathic and two parathyroprive. The blood calcium did not exceed 6 mg. per 100 c.cm. in any of them. I therefore began by giving 10 c.cm. of A.T. 10 on the first day and 5 c.cm. on the second and third days. Thereafter 1 to 2 c.cm. was given daily for a short time. In all the patients the calcium content of the serum increased considerably after three to five days and the symptoms of tetany disappeared. After the first ten days a dose of 1 to 2 c.cm. three times a week was usually sufficient to keep the calcium content normal. All other therapeutic measures could be stopped a day or two after the beginning of the A.T. 10 treatment.

This simple oral method of handling tetany is a great improvement on previous techniques; it can only be applied, however, in cases where the calcium content of the serum can be watched, as otherwise there is a risk of accumulation. For this reason the manufacturing firms only put A.T. 10 at the disposal of clinicians working in hospitals where calcium analyses are done regularly.

CASE RECORDS

CASE 4.—A woman, aged 42, had had thyroidectomy performed in 1924 and again in 1932. After the second operation, cramps in the hands, feet, and head had appeared, and a month later had become worse, being accompanied by epileptiform seizures. The latter disappeared under parathormone and calcium treatment and the tetany was relieved, but she still suffered from rigidity of the hands and feet and speech difficulties. Chvostek, Trousseau, and Schlesinger signs remained positive. The calcium content of the serum varied between 4 and 6 mg. per 100 c.cm (Table III.). The inorganic phosphorus of the blood was considerably increased: 5·5 to 6·2 mg. per 100 c.cm. The teeth showed caries and white patches, but the nails were normal and there were no symptoms of cataract. To attain this state of affairs the patient had to receive 80 units of parathormone subcutaneously and two 10 c.cm. doses of Calcium Sandoz intravenously, with three drops of vitamin D thrice, every day. Every attempt to reduce this intensive treatment was followed by severe attacks of tetany. Three transplantations of human parathyroid were made without result. On Sept. 25th, 1932, the calcium content of the blood was 4·8 mg. and the inorganic phosphorus 6·04.

* 1 c.cm. A.T. 10 every second day from Oct. 9th to 17th.

† None from Oct. 17th to Nov. 7th.

‡ 2 c.cm. A.T. 10 every second day from Nov. 9th to 18th.

A.T. 10 treatment was started on Sept. 27th, 10 c.cm. being given on the first day and 5 c.cm. on the second and third days. On the fourth day the calcium content of the serum was 8·8 mg., but the phosphorus was not increased. All other methods of treatment were then stopped and the patient for the next ten days was given 1 c.cm. of A.T. 10 for two days, missing the third day. The calcium and phosphorus values then read 8·99 and 3·97 mg. per cent. respectively. From Oct. 9th to 17th 1 c.cm. was given on alternate days and the calcium and phosphorus readings were 10·95 and 3·86 mg. per 100 c.cm.

The A.T. 10 treatment was then stopped for three weeks until Nov. 7th. The blood calcium diminished to 7·3 mg. and the phosphorus went to up 4·63. On Nov. 7th the patient had a definite attack of tetany. She was therefore given A.T. 10 in daily doses of 2 c.cm. for three days and then 2 c.cm. every other day. After a week the calcium had gone up to 8·65 mg. and the phosphorus had gone down to 4·27. After ten days, normal values of both were found.

In this very severe case of parathyroprive tetany, where even large subcutaneous doses of parathormone and intravenous calcium failed to obtain a satisfactory result, A.T. 10 worked like magic. The second case shows a similarly favourable result.

CASE 5.—A woman, aged 48, was operated on for goitre in 1920 and in 1931. A month after the second operation she complained of pricking in the fingers, vertigo, headache, and fatigue, and the diagnosis of parathyroprive tetany was made in Germany in November, 1931. She received injections of a German parathyroid preparation for five months without benefit, and in April, 1932, severe cramps with general rigidity and cyanosis developed. In July she showed all the symptoms of latent tetany. She had severe hypocalcæmia and an increase of inorganic phosphates. At first she would not take parathormone injections because she thought she got sufficient relief from taking calcium and vitamin D by the mouth. In December, however, she suffered so much from general weakness and fatigue that she began taking 20 units of parathormone on alternate days, continuing to take calcium and vitamin D. On this treatment her condition was satisfactory but she always showed symptoms of latent tetany; she was always tired and her blood was hypocalcæmic (6 to 7 mg. per 100 c.cm.). Under parathormone treatment, however, the inorganic phosphorus became normal (Table IV.).

A.T. 10 treatment was started on Oct. 17th, 1933: 5 c.cm. on the first day, 10 c.cm. on the second day, 5 c.cm. on the third day, and 2 c.cm. on the fourth day. *On the fifth day the calcium in the serum had increased* from 6 mg. per 100 c.cm. to 8·4 mg. In the six succeeding *days she was given 1 c.cm. of A.T. 10 daily and thereafter* 1 c.cm. on alternate days. All other treatment was stopped when the A.T. 10 treatment was started. The calcium remained about 9 mg. per 100 c.cm., and the general condition improved rapidly. The patient felt much better and was able to resume her normal activities.

CASE 6.—A man, aged 48, had a long-standing idiopathic tetany. At the age of 30 he had developed double cataract which had been operated on four years afterwards. Apart from this he had felt quite healthy until 1927, when he had complained of fatigue and cramps in the fingers, especially when overworked. In January, 1933, he had an attack of acute tetany in the street, and after that his fatigue increased so much that he could not continue working; his nails crumbled away and attacks of tetany appeared from time to time. In January, 1930, he showed severe hypocalcæmia and high phosphate content (6 to 6·5 and 5 to 6·6 mg. per 100 c.cm. respectively). Two parathyroids were transplanted with no effect at all. Parathormone injections were given between July 7th and 31st, and the serum calcium rose to 10 mg., the serum phosphate dropping to 3·36. As soon as the injections were stopped the calcium content decreased again to 6 mg. The man attended the out-patient department regularly; although he had severe hypocalcæmia all the time his only complaints were fatigue and chilliness. This is in accordance with the general experience that symptoms of chronic tetany become less marked after a lapse of time. Nevertheless, the patient was a chronic invalid unable to do regular work.

A.T. 10 treatment was started on Nov. 16th, 1933: 10 c.cm. on the first day and 5 c.cm. on the second and third days (Table V.). The calcium and phosphorus readings on the third day were 4·8 and 7·1 mg. per 100 c.cm. respectively, but the dose was nevertheless decreased and 2 c.cm. given for the next two days; then the calcium content was found to have risen to 7·01 mg. For a week 1 c.cm. was given every other day and the calcium and phosphorus readings were then 9·34 and 5·4 mg. respectively. The calcium remained normal and the inorganic phosphate went down to 4·5 mg. under doses of 0·5 and 1 c.cm. of A.T. 10 every few days. The patient became another man under this treatment. He had much more energy and no longer suffered from chilliness. His skin, previously extremely dry, became normal; in fact he only discovered how much he had suffered from his chronic hypocalcæmia when his blood calcium was restored to normal.

SUMMARY

(1) The transplantation of parathyroids for the treatment of tetany does not have a lasting effect although in exceptional cases it may save life. (2) For milder cases the administration of calcium and vitamin D by the mouth is often enough. (3) In most of the more severe cases improvement can be obtained by intravenous injections of calcium and subcutaneous injections of parathormone. (4) A great improvement in the methods of treatment available is represented by oral administration of A.T. 10, a by-product of the irradiation of ergosterol, small doses of which will restore the blood calcium to normal level in the severest cases of tetany, both parathyroprive and idiopathic. (5) The cumulative action of A.T. 10 must not be overlooked; after initial doses of 5 to 10 c.cm. for three days the dose must always be reduced to 1 or 2 c.cm. daily for ten or fourteen days, after which 1 to 2 c.cm. three times a week is sufficient, even in the severest cases.

THE MECHANISM OF HOMOLOGOUS TUMOUR IMMUNITY

BY T. LUMSDEN, M.D. Aberd.

T. MACRAE, B.Sc., Ph.D.

AND

E. SKIPPER, M.D., M.R.C.P. Lond.

(From the Cancer Research Laboratory, London Hospital)

IN a paper[1] on the nature of immunity to transplanted tumours, published by one of us (T. L.) in 1927, it was stated that in the case of immunity against a homologous tumour—for example, in a rat immune to Jensen's rat sarcoma (J.R.S.)—anticancer bodies were present in the immune animal's serum. This conclusion, vigorously opposed in certain quarters, was inferred from a number of experimental observations, but it could not at that time be directly demonstrated on tissue cultures of the tumour cells concerned. This difficulty has been surmounted and the presence of antimalignant-cell bodies can now be shown directly and conclusively by applying the immune rat's serum to cultures of J.R.S. cells in vitro under appropriate conditions.

The probable reason why this fundamental observation eluded previous investigators is that its vivid demonstration requires the coincidence of three separate conditions or factors, each of which, although contrary to expectation, is yet essential.

In order that the immune serum shall invariably kill the J.R.S. cells to which it is applied it is necessary that:—

1. The serum be drawn soon, preferably on the third day, after the last immunising inoculation. The titre of antibodies rises rapidly for the first 48 hours, thus

---

[1] THE LANCET, 1927, i., 116.

attaining its maximum unusually early. From 48 to 96 hours it is at its highest, and it falls again equally rapidly, so that by the sixth or seventh day it may be so low as to be difficult to demonstrate.

2. The serum should be applied to young (24 hours old) actively growing J.R.S. cultures. With older cultures the reaction is much less striking.

3. The serum must be applied directly after it has been prepared, since the antibodies are exceedingly labile and may become ineffective if kept at laboratory temperature for an hour or two.

The characteristic effect of a strong serum is that it kills the J.R.S. cells within 10–30 minutes. The cells swell up, their nuclei become sharply defined and shrunken, and the fatty and protoplasmic granules agglutinate. If stained after 6–8 hours the nuclei are found to be pyknotic, while if 24 hours are allowed to elapse before staining, complete chromatolysis is seen to have taken place. Cultures of normal tissue cells are entirely undamaged by these powerful anti-cancer sera.

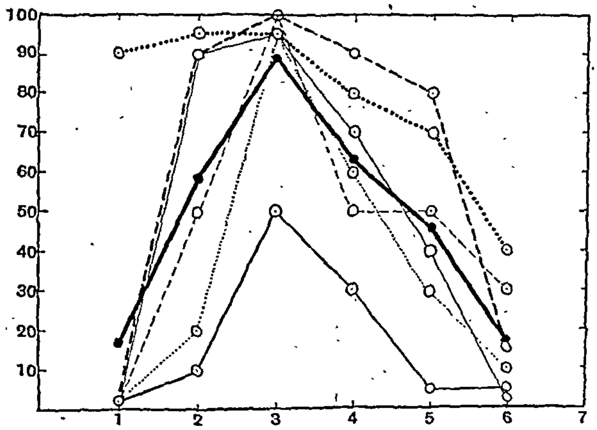

Chart showing the anti-cancer-cell potency of the sera of six rats immunised against a homologous tumour. The abscissæ show the percentage of migrating J.R.S. cells killed by the respective sera, while the ordinates represent the period at which the sera were drawn, in days, after the last injection of antigen (J.R.S.). The darkest black line is the average of all the observations; the other lines represent daily the variations in the titre of the serum of each of the six rats. All the cultures used were of comparable vigour each containing several hundreds of actively migrating sarcoma cells.

When the above precautions are taken the results are characteristic and consistent in 100 per cent. of the experiments; the sera of a rat hyper-immunised against J.R.S. kill the actively migrating J.R.S. cells, whereas control sera from normal rats similarly drawn and applied have no damaging effect at all on the J.R.S. cultures.

A full account of the methods, protocols, and evident extensions, of the experiments here referred to, will be published in the near future. It may suffice in this preliminary note to illustrate in graphic form one typical experiment showing the rise and fall of the titre of the anti-cancer bodies and their effects in a series of six rats.

We draw the following conclusions: (1) That the presence of an effective titre of anti-cancer bodies is demonstrable in the serum of an animal immunised against a homologous tumour. (2) That the existence of these antibodies provides an adequate explanation of the mechanism of homologous tumour immunity.

The experiments referred to above have been performed with the help of grants from the British Empire Cancer Campaign, which have made it possible for each of the three authors to devote his whole time to cancer research.

THE INCIDENCE OF ADENOMA OF THE PITUITARY BODY IN SOME TYPES OF NEW GROWTH

BY H. G. CLOSE, M.D. Lond.

ASSISTANT BACTERIOLOGIST AND LATE GRIFFITHS DEMONSTRATOR OF PATHOLOGY, GUY'S HOSPITAL

THE incidence of tumours in endocrine glands has recently become a matter of importance, since it is now clear that the presence of these tumours is associated in many instances with the effects of hypersecretion of their respective glands. In a series of pituitary bodies obtained from routine post-mortem examinations at Guy's Hospital in the past 18 months, not only was the incidence of tumours in the pituitary body one of the principal objects of investigation but their presence in relation to clinical signs or symptoms was also noted.

Unfortunately, it was not found practicable to examine the pituitary body in every case, and the first *200 glands* were collected from 450 consecutive cases. This group cannot, therefore, be called a true random sample, but on the other hand no deliberate choice was exercised. The selection was determined by the necessity of opening the skull—as, for example, in all cases of accident and sudden death (33); in all cases of probable cerebral involvement (40); and in many instances where a brain was required for anatomical purposes (127). In this way it was found possible to obtain a fairly representative number of both sexes (132 males, 68 females) and all ages, the average number for each decade between the ages of 10 and 70 being 30.

On removal from the sella turcica the pituitaries were fixed in 10 per cent. formol saline and cut in the horizontal plane—i.e., through the equator if the stalk were to represent the north pole. The sections were stained both with hæmatoxylin and eosin in the usual way and with a slight modification of Mallory's connective tissue stain. The use of some stain such as the latter is essential if the cells of the anterior lobe are to be classified correctly as chromophobe, acidophil, or basophil.[1]

In an investigation of this nature where all degrees of deviation from the normal appearance of the pituitary may be encountered, it is imperative that the term "adenoma" should be clearly defined. "Adenoma" is used here to describe a grouping together of one of the three types of cells found in the anterior lobe. An arbitrary limit for the diameter of an adenoma was fixed at 0·8 mm., the smallest found, but the majority of these tumours can be seen easily in the stained sections by the naked eye. The nodule of growth may be solid or partly cystic and may or may not have a fibrous boundary, but is easily distinguishable from the neighbouring cells by alterations in the arrangement, size, and shape of the cells. The normal acinose plan is lost, the stroma is often scanty, and the cells are smaller than normal. The not infrequent hyperplasia of cells confined to one acinus only has not been regarded as adenoma, and doubtful "border line" tumours have been rejected.

An examination of a few sections only from the plane through which the pituitary had been cut was made at first and revealed several points of interest. For example, in the first 200 pituitaries collected as described above, an adenoma was found in 18—i.e., the incidence of pituitary adenomata is probably at least 1 in 10. This is in agreement with the findings of other investigators.[2,3] It was also noticed that most of these adenomata were present in subjects of more than 45 years of age who had, in addition, a benign or malignant new growth in some other part of the body.

Attention was thereupon directed to testing the correctness of this latter observation: 125 pituitaries were subjected to serial sectioning, 75 from cases of proved new growth occurring elsewhere in the body, and 50 from "control" cases. The latter, the "controls," were subjects of 45 years of age or more in whom routine post-mortem examination (conducted with varying thoroughness, particularly in regard to the thyroid and sex glands) revealed to the naked eye no obvious new growth. Serial sections were cut at a thickness of 7µ and from six to twelve sections were placed on each slide, about forty slides being required for a normal-sized pituitary. Every fourth slide was stained and examined. Five of the "control" cases had an adenoma of the pituitary—an incidence of 1 in 10—and the sex, age, and post-mortem diagnosis in these cases are briefly as follows:—

1. Male, 54 years. Gastro-jejunostomy four months before dying of acute pancreatitis.
2. Male, 60 years. Gastro-jejunostomy six years before dying of acute duodenal obstruction.
3. Male, 54 years. Inguinal hernia for 20 years before it strangulated. Had a generalised hyperplasia of lymphoid tissue and a persisting thymus.
4. Male, 55 years. Died of cerebral hæmorrhage.
5. Male, 62 years. Died on admission. Thrombosis of coronary arteries of heart.

In four other cases of cerebral hæmorrhage and four other cases of sudden heart failure no adenomata were found in the pituitary.

INCIDENCE OF ADENOMATA

The most striking feature of the Table is the comparatively high incidence of pituitary adenomata in cases of adenoma of the prostate and carcinomata of the pancreas, rectum, and bronchus. In the "control" cases the incidence of pituitary adenomata is only 1 in 10, so that even if the figures are too small statistically to allow definite conclusions to be drawn, they nevertheless suggest that some association exists between pituitary adenomata and certain kinds of new growth. What form this association takes is not at all clear, but four possibilities may be suggested.

First, it is well recognised that the pituitary plays some part in the growth of the body considered as a whole. Evans and others have produced gigantism in animals by injections of extract of anterior lobe [4]; and the frequent association of acidophil adenoma with acromegaly also points to a hypersecretion of the anterior lobe as the probable cause of increased stature. There is, however, no reason to believe that the pituitary can also exert this influence locally to form a new growth, though it may perhaps affect the rate of growth in one particular part, as for example in a neoplasm.

There is a striking difference in the histological appearance of a pituitary taken from a case where there is a slowly growing tumour—e.g., an epithelioma—and one taken from a case where there is a rapidly growing tumour—e.g., a sarcoma. In the epitheliomata the anterior lobe appears to be almost inactive. There are abnormally few cells in each acinus and the stroma is swollen with a "colloid"-looking substance. In the sarcomata, on the other hand, the appearance of the gland suggests a state of great activity. The acini are packed with the increased number of cells and the stroma is inconspicuous. In the cases of glandular carcinomata no correlation has yet been found between the degree of malignancy (as measured by the tendency to infiltrate and metastasise) and the presence of pituitary adenomata or cellular hyperplasia. But if the rate of growth of an active tumour in the body is increased when a pituitary adenoma is present, it would be difficult to explain the frequent association of pituitary adenomata with the less active forms of new growth, such as adenoma of the prostate.

The second suggestion to be put forward may perhaps overcome this difficulty. It is possible that the formation of a tumour in the pituitary, such as an adenoma, is only one indication of a constitutional tendency to tumour-formation in all the glands. For, as the Table shows, the incidence of pituitary adenoma is high in cases of new growth in other glands (adenoma of the prostate and glandular carcinomata), while in cases of epitheliomata not one pituitary adenoma was found. Excellent examples of cases showing widespread tendency to tumour-formation of glands have been described by Cushing and Davidoff [5] and by Simpson.[6]

Thirdly, as very little is known of the effect on the body of a chromophobe cell adenoma in the pituitary, it is possible that an undetected syndrome is associated with the pituitary adenoma present in those types of new growth which have a high incidence of pituitary adenomata as well as in the five "control" cases.

The last of the four possibilities—and the least likely—is that the presence of pituitary adenoma is accidental and unrelated to the presence of other new growths or to a syndrome common to them and to the control cases.

Carcinoma of the pancreas.—The fact that a pituitary adenoma was found in most cases of carcinoma of the pancreas is one more example of the close relationship between the pituitary and the pancreas. Among the other examples are, briefly, the changes which occur in one organ when the other is removed experimentally [7, 8]; the mutual antagonism of posterior pituitary extract and insulin [9]; the incidence of diabetes mellitus (12 per cent.) and glycosuria (25 per cent.) in acromegaly [10]; the finding of glycosuria also in cases of basophil cell adenoma of the pituitary.[11]

Adenoma of the prostate gland.—The association of chromophobe adenomata of the pituitary with adenomata of the prostate gland may also be explained on a physiological basis. One of the secretions of the anterior lobe of the pituitary is known to have a gonadotropic effect [12]; and in hypophysectomised rats, feeding with the "anterior pituitary-like substance" (Collip[13]) led to great hypertrophy of the accessory sexual organs. It should be noted, however, that most of the pituitaries in cases of carcinoma of the prostate appear to be normal histologically. Of the 10 cases of adenoma of the prostate shown in the Table, three were also cases of Paget's disease of bone, and in two of these there was a chromophobe adenoma in the pituitary.

Carcinoma of rectum.—Little can be said as to possible reasons for the fairly frequent occurrence of pituitary adenomata in this disease. But in view of what has been suggested above—namely, that the pituitary lesion might be one expression of a general glandular involvement—it may not be coincidence only that pituitary adenomata were present in 6 out of 10 cases of carcinoma of the rectum, while in approximately 7 out of 10 cases (25 out of 33 actually) of this type of carcinoma, adenomata of the rectum were present before malignant changes supervened (Dukes[14]). Thus the incidence of pituitary adenoma and of rectal adenoma in cases of carcinoma of the rectum is very nearly the same.

THE NATURE OF THE PITUITARY ADENOMATA

Of the 280 pituitaries collected, nearly half of which have so far been cut in serial sections, 39 were found to contain an adenoma. In all but two the adenoma was composed of chromophobe cells or almost entirely of chromophobe cells, for careful searching will often reveal the presence of one or two cells of other types.

There were two very small adenomata of the acidophil cells of the pituitary—one in a case of carcinoma of the rectum and the other in a case of carcinoma of the bronchus, and neither showed any of the classical signs of acromegaly, or even of gigantism.

No adenoma of the basophil cells was seen but, in a case of carcinoma of the colon in a female 69 years old, there was an adenoma-like collection of those basophil cells which are frequently seen passing back into the posterior lobe from the region of the cleft.

There were two instances of a secondary deposit in the pituitary. The malignant growth in one case was a carcinoma of the bronchus, and in the other a lymphosarcoma.

Most of the adenomata seen were too small to give rise to symptoms, and it was only possible to diagnose one of the 39 clinically. But not every large adenoma gives an indication of its presence. One adenoma, nearly double the size of a normal pituitary, had remained symptomless even though it had grown out of the pituitary fossa. Presumably, in pushing its way backwards and outwards between the posterior clinoid process and the internal carotid artery, it had met with no resistance from structures which give rise to symptoms on being disturbed.

SUMMARY

The incidence of adenoma of the pituitary gland was approximately :—

(a) 10 per cent. in all cases.
(b) 44 per cent. in cases of carcinoma of other glands.
(c) Over 50 per cent. in cases of :
  adenoma of the prostate gland ;
  carcinoma of the pancreas ;
  carcinoma of the rectum ;
  carcinoma of the bronchus.

The majority of these pituitary adenomata (38 out of 39) gave rise to no known clinical signs or symptoms.

I am grateful to Prof. G. W. Nicholson and Dr. Dorothy Russell for checking my results ; and to Dr. A. A. Osman, Dr. P. P. Laidlaw, the Medical Research Council, the Clinical Research Committee of Guy's Hospital, and particularly to an anonymous donor, for their help.

SIMPLE FIXTURES ADAPTING A TABLE FOR CRANIAL OR SPINAL OPERATIONS

BY ARNOLD K. HENRY, M.B. Dub., F.R.C.S. Irel.
PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY OF CAIRO

THE fixtures here described allow a table ordinarily used for general surgery to be modified, in a simple way, for operations on the skull or spine. The advantages of these fixtures are shared by the anæsthetist and the surgeon.

THE FACE-DOWN FIXTURE

Tables used at present for spinal or cerebral operations in the face-down position usually have supports for the patient's shoulders, which project up from the top of the table itself. The patient's forehead, on the other hand, rests at a distance from the table determined by the length of his neck. If the neck is short his mouth and nose touch, or almost touch, the end of the table. This unfairly cramps the anæsthetist during the long sessions of cranial surgery and puts a sore tax upon his skill. The surgeon, for his part, is often, as I know, constrained to fit long or short patients to a fixture of average size.

The new fixture removes both difficulties. (1) It eliminates neck-length as a cramping factor by supporting the patient's shoulders at points beyond the end of the table ; his face lies then still further off, and gives the anæsthetist full access to the mouth and nose. (2) It can be easily adapted to all patients, whether small infants or the largest men.

The face-down frame (*Fig. 1*).—A rigid metal frame fits into the slots that ordinarily carry the foot-piece of the Thackray table. On each side of the frame there is a short transverse bar which can travel backwards or forwards, and each short bar carries a crutch-like shoulder-support. The six-inch gap between these bars gives clear access to the face of the patient, however short his neck, while their mobility backwards and forwards allows adjustment for every length of trunk.

The shoulder supports are fixed in height, and each can slide in or out along its short bar according to the patient's width of shoulder. The supports have *curved* stems and are reversible. At their widest, when the stems diverge, they fit the very broadest individuals ; when reversed and close together they fit the smallest child. They can at once be adjusted to any patient of intermediate width.

The head-rest.—The front of the frame carries the head-rest—a semicircular, malleable band padded with sponge rubber ; it is fixed to a stout horizontal bar that slides through a vertical one, and can thus be moved backwards, forwards, or vertically ; a thumb-screw makes it fast. The bars that carry the head-rest are long enough to permit adjustment for any length or inclination of the neck. Two sizes of head-rest have been found sufficient; both are hinged to the horizontal bar in such a way that the angle they form with it can be varied at will.

Rests for the patient's wrists keep the upper limbs alongside the trunk; the arms otherwise hang vertically.

Position of the table.—For the face-down posture the top of the table may be pumped to its maximum height of 40 inches or, if the surgeon prefers to operate with the patient's head well raised above the level of the trunk, the whole table is tilted and then brought to any height that is convenient for access. The surgeon and the assistant stand on stools.

The anæsthetist on a low seat with his back to the table has plenty of head-room beneath the frame. In front of him, below the support for the patient's head, is a shelf for bottles and instruments. Stainless steel hooks are provided to hang on the frame for the purpose of taking a sphygmomanometer dial or a tongue-forceps; a larger adjustable hook forms a convenient rest for the arm of the anæsthetist (Fig. 2).

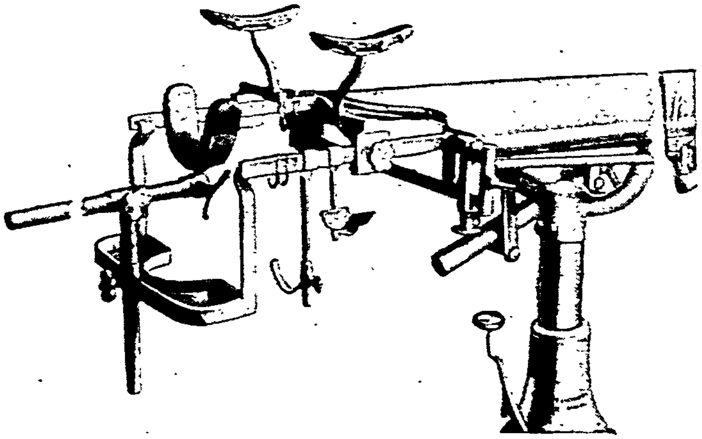

FIG. 1.—The face-down fixture, showing the frame which fits into the ordinary foot-piece slots of the table. The frame carries shoulder supports with curved stems, and a head-rest; both are adjustable to patients of every size. Note the anæsthetist's shelf and arm-rest.

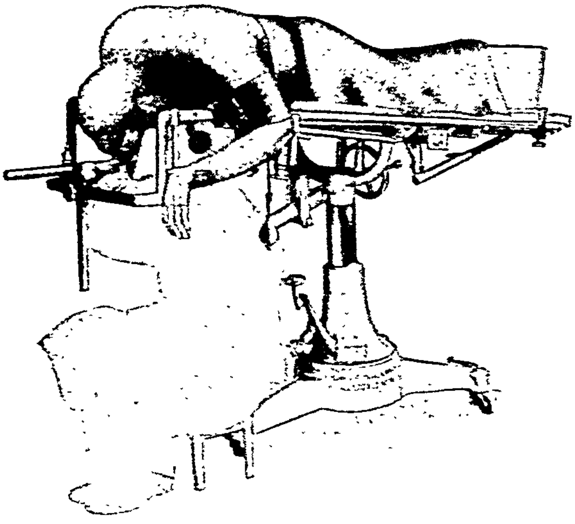

FIG. 2.—The face-down fixture in use. The anæsthetist beneath the frame has ample head-room and easy access to the patient's face. Note the wrist supports.

THE FACE-UP FIXTURE

The second fixture (Fig. 3) was designed in the first place to give free access—from beneath—to the back of the skull. Its primary purpose was to remedy a disappointing feature of the ventriculographic puncture, in which an outflow of cerebro-spinal fluid that begins well may often stop after the substitution of only a few cubic centimetres of air.

Apart from the accident of displacing the needle's point from the ventricle the cerebro-spinal outflow fails, I believe, because the needle is often introduced posteriorly when the head is lying more or less on its side; the needle does not therefore enter the bottommost part of the ventricle. Obviously, however, the only sure way of aspirating all the fluid from a closed sac and replacing it with air is to puncture the sac at the bottom, and nowhere else—a thing difficult in the cerebral ventricle without a special support for the head.

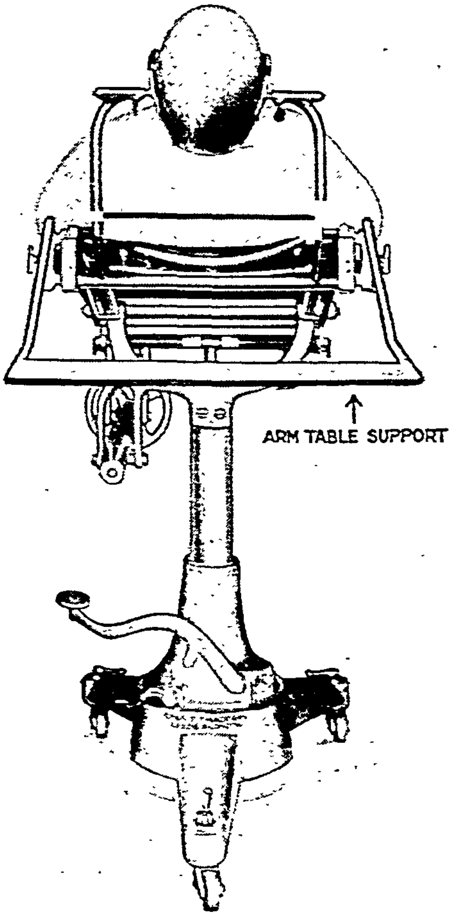

FIG. 3.—The face-up fixture arranged for ventriculographic puncture. The surgeon rests his elbows on the arm-table, which is adjustable in height. The head-supports allow free access to the neck of the skull.

Construction.—The face-up fixture consists of a frame, concave upwards, which fits, like its face-down fellow, into the foot-end of the Thackray table; it carries two narrow crescentic supports, which can be made to grasp any skull on either side, just behind the mastoid process. The surgeon, seated on a stool and working from below, has then a wide field between the crescents for tapping the ventricle at the lowest possible level. A convenient arm-table steadies and supports his elbows.

The face-up fixture is used for (*a*) frontal, and (*b*) parieto-temporal craniectomy.

(*a*) For frontal exposures the head lies face up as it does for ventriculography.

(*b*) For a wide parieto-temporal approach one crescentic support is adjusted beneath the head to the occiput; the other, set nearly at right-angles to the first, passes obliquely above and close behind the ear, supporting the parieto-occipital region on the side opposite the field of operation. The pivotal points of the two supports should be kept close together when adjusting them for this exposure.

THE PERINEAL SADDLE

Lastly, and at the suggestion of my friend Mr. Adams McConnell, a perineal support, shaped like a bicycle saddle, has been added to the table. This support, together with a pair of foot-rests, is easily slid on to the ordinary fittings of the table; it prevents all risk of the patient slipping down from the reversed Trendelenburg position required for many intracranial operations. The saddle is adjustable to patients of different length, and is also reversible for use in the face-up or face-down postures.

My best thanks are due to Messrs Thackray, of Leeds, who have made the fixtures from my design, and to their experts, Mr. Beardmore and Mr. Blackburn, for their admirable coöperation.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF MEDICINE

At a meeting of this section held on March 27th the chair was taken by Sir **Farquhar Buzzard**, the president, and a discussion was held on recent advances in the

Pathology and Treatment of Lymphadenoma

Dr. **Mervyn Gordon**, dealing with the pathology, said that lymphadenoma occupied an intermediate position between granulomata of known ætiology and malignant disease, and the problem of its causation might therefore be a key position to the problem of sarcoma. In a typical case the diagnosis could be made from sections of an enlarged gland, when the three characteristic changes were present: fibrosis, giant cells, and eosinophils. In practice, however, one or more of these three changes was often lacking. There were probably a number of different conditions, largely hitherto undifferentiated, in these atypical cases. The term "Hodgkin group" was a convenient one for the series of gradations between typical lymphadenoma and typical lymphosarcoma. The course of the disease was very suggestive of an infective agent, but the uniform fatality resembled malignant disease. So far lymphadenoma had not been certainly identified in or communicated to animals. It seemed possible that the ætiological agent would prove to be more nearly allied to that of sarcoma than of the granuloma-producing agents.

Recent work at St. Bartholomew's Hospital had included search for a pathogenic factor in lymphadenomatous glands by microscopical and other studies and work on allergic tests. No evidence had been found of spirochætal, tuberculous, or mycotic infection. Twort had found that lymphadenoma gland suspensions might cause local inflammatory nodules when injected into guinea-pigs; this had been confirmed and some very pronounced reactions noticed. In one case serial passage of this local subcutaneous granuloma had been obtained through eight guinea-pigs, the material being sterile throughout. Unfortunately this reaction could not be produced invariably.

A virus causing lymphogranuloma inguinale had been demonstrated by means of cerebral inoculation, and this procedure had therefore been used to investigate lymphadenoma. An encephalitis, frequently fatal, had been produced in the rabbit and guinea-pig, though not in the mouse or monkey, by inoculation of gland suspensions. After one to seven days susceptible animals showed symptoms such as fits, salivation, tremor, head-turning, and paresis, but the characteristic condition was one of incoördination and ataxia with muscular rigidity and spastic gait, occasionally also opisthotonus. Dr. Gordon showed slides and a film illustrating this condition. Application of this test to diagnosis showed 30 positives and 5 negatives during the last three years. Glands from other conditions gave negative results. The reaction could be obtained after heating the material for 30 minutes to 65° C. The test was of chief value in early cases; it might be negative with glands from chronic cases. The strongest reaction appeared when all the cardinal histological changes were present in the glands.

The active agent thus obtained was inactivated by keeping for half an hour at 80° C. and apparently increased when a suspension was kept by autolysis of cells. It was filtrable and withstood antiseptics well, but was gradually attenuated by ether. Moderate doses of X rays did not inactivate it. Successful passage had not been obtained, but there was evidence for the existence of both passive and active immunity, though both were very difficult to obtain. The agent was not likely to be a proteolytic enzyme. It might be complex and partly derived from the cells. An encephalitogenic agent was present in marrow and pus, but this did not invalidate the diagnostic value of the rabbit test. Bodies closely resembling the elementary bodies (Paschen) of vaccinia were found in large numbers in suspensions of lymphadenoma glands. No evidence of specific allergy had been obtained.

Dr. A. E. Gow said that the term lymphadenoma did not denote a single disease but several morbid processes which showed minor differences in clinical characteristics, course, prognosis, and therapeutic response. The histological changes were found in the reticulo-endothelial cells of lymphoid tissue, and both endothelial and reticulum cells showed overgrowth. Mononuclear elements obscured the normal structure of the gland. Endothelial cells gave rise to the typical giant cells, but in some cases mononuclear cells predominated, and there was no fibrosis and few giant cells. Considerable laboratory support was available for the theory that lymphadenoma was a virus infection, but clinically the condition did not resemble any other virus disease except oriental bubo (lymphogranuloma inguinale) and perhaps psittacosis. Specific treatment had so far proved unsuccessful. Chicken serum had been tried, and also a suspension from the patient's own glands. The latter seemed to contain some active agent, as its injection was followed by temporary relief of pruritus and swelling of the nodes in face and neck. Dr. Gow described the technique of treatment and the course in several cases, and also the attempts made to diagnose Hodgkin's disease by an intradermal allergic test. The great majority of tests had given negative results, but in three instances where the disease seemed to be "resting" a small local reaction had been seen. He also showed a number of slides illustrating the histology. There could be no doubt, he said, that life was prolonged by irradiation, and the periods of remission were increased in length, and patients were able to resume their occupation, apparently well.

A paper by Dr. W. M. Levitt was read by Dr. R. F. Phillips. The radiologist, he said, wanted to know from the physician what to treat. Further progress could only result from coöperation. A localised focus could be made to disappear, almost for certain. The doses were considerably below the tolerance limit of healthy tissues and much might be lost by attempting to use larger doses. Any increase should be in the number of areas treated. Histologically as well as clinically the lesions disappeared, but the disease was not cured. Recurrences appeared, and sooner or later became so widely disseminated in chest and abdomen that adequate doses could no longer be applied. Nevertheless palliative treatment could still be used; pressure symptoms and early cachexia could be relieved. In the final stages the disease became more resistant to X rays. Almost magical in early stages, X ray treatment might be worse than useless in the late stages. The palpable mass was not necessarily the original focus, which might really lie in deeper tissues. An initial lesion which escaped treatment would act as a centre for spread. The disease required study from the angle of distribution and march. Finzi taught that the mediastinum should be treated in every case, whatever the apparent lesion, but the abdomen presented a more difficult problem because of the effects of X rays on the organs. It was arguable that the abdomen ought to be treated as a routine measure. The chief palliative measure was the "X ray bath," an exposure of wide areas to repeated small doses. Radiologists now knew the dosage for "baths" of all areas except the trunk, where there was still some danger of leucopenia. The results of abdominal baths had so far proved only temporary.

Prof. U. Friedemann suggested that there might be two agents, one producing the encephalitis in rabbits and the other the allergic skin reaction. He had found that normal bone-marrow injected cerebrally produced the same picture, and thought more depended on the site of injection than on the material injected.

Dr. C. E. van Rooyen mentioned some of the many clinical conditions described by Hodgkin. The biological test was one of the greatest value, which had been confirmed in Edinburgh and Glasgow. A gland which contained very large numbers of leucocytes gave a persistently negative reaction and the specificity of the test seemed clear. The parasite seemed to be intracellular; the reaction was produced by something that was coming out of a cell. It might be a living agent, a toxic product, or a ferment. In the absence of inclusion bodies and animal transmission it could not be called a virus. But neither typhoid, leprosy, nor syphilis had ever been satisfactorily transmitted to animals. He thought it was a toxin. Virus infection in a cell might cause degeneration and death or proliferation; lymphadenoma was a proliferative phase.

Dr. F. Parkes Weber offered another explanation of Hodgkin's disease; he did not believe that the evidence for infection was by any means conclusive, and thought there was just as much to be said for the neoplastic theory. By neoplastic disease he meant a proliferation which served no useful or conservative purpose to the organism and for which no causative agent had been discovered. It might be benignant or malignant. The myeloses were malignant proliferation of the leucopoietic system of the body. Erythræmia was benignant proliferation of the erythroblastic system. Hodgkin's disease was, perhaps, a more or less malignant proliferation of the reticulum—a reticulomatosis. It was characteristic of neoplastic cells that they could continue their ordinary work to some extent. The reticulum was able to form all the cells found in every type of Hodgkin's disease.

MEDICAL SOCIETY OF LONDON

A meeting of this society on March 26th, with Mr. R. Davies-Colley in the chair, was devoted to a discussion on

Functional Disorders of the Bowel

Dr. T. L. Hardy (Birmingham) pointed out that many of the terms applied to colon dysfunction—such as visceroptosis, muco-membranous colitis, atonic constipation, and colon spasm—were inaccurate and needed revision, though they indicated that the neuromuscular imbalance of the bowel had a variety of phases. The tone, coördination, and harmony of the intestinal movements depended on the extrinsic autonomic nervous system; the sympathetic fibres were inhibitory to the bowel and caused contraction of the sphincters, while the parasympathetic was predominantly motor and inhibited the sphincters. Physiologists, however, held that these nervous influences were affected to some extent by the state and tone of the muscle at the time. Further knowledge of this subject could be expected not from animal experimentation but rather from operations on the sympathetic nervous system and observations on the effects of such drugs as atropine, adrenaline, and acetylcholine.

The functional disorders of the colon could be regarded as due to an imbalance between the nervous and the muscular apparatus, which resulted in disturbance in mechanical and secretory activities—a disturbance made known to the patient by symptoms such as abdominal discomfort or pain, distension, and the abnormal elimination of fæcal material. Often there was a psychical or emotional factor in addition. It was hard to estimate the frequency of these disorders, especially as the intestinal neuroses diminished in frequency with descent of the social scale. At Birmingham General Hospital, out of 1078 patients admitted on the medical side for chronic disorders of the digestive system, there were 85 of colon dysfunction (8 per cent.), but E. I. Spriggs, and Jordan, of New York, published figures giving a much higher proportion. Of 157 patients treated by the speaker 89 were females and 68 males; the greater proportion were in early middle life, 51 being aged 31–40, 29 41–50, and 27 21–30. Some of the late results of dysenteric and non-specific inflammations seemed to be due to an irritability of the neuromuscular mechanism, and were periodically made evident by attacks of diarrhœa; also chronic disease of the gall-bladder and appendix commonly caused reflex disturbances of colon function, and thus provided a good many diagnostic difficulties. Similarly an inflamed Fallopian tube or ovary might set up spasm in an adjacent coil of bowel, and influenza and upper respiratory disorders might play a part. Achlorhydria as a predisposing cause of disorders of the colon was rare, but dietetic factors were important, and some of the modern food cults did not encourage healthy action of the bowel. The colon dyspeptic reduced his total intake to relieve his indigestion, but he really aggravated it by increasing his constipation. The chief rôles in causation must be assigned to constipation and its treatment by excessive purgation, and to nervous instability. Constipation was complained of by the vast majority of patients—e.g., by 106 of his 157—77 of whom were taking irritant aperients daily. The drugs most commonly used were vegetable laxatives, such as rhubarb, aloes, cascara, and senna, and the synthetic product phenolphthalein, the last of which seemed especially harmful, since it was in part absorbed and excreted in the bile, and might go on acting over three or four days. Its continued use resulted in the passage of much mucus, and sometimes in hæmorrhoids.

Emotional upset and fatigue were common causes of functional disorder of the colon, as also were cold winds and tobacco. Abnormal mental reactions characterised many of the patients, especially tall thin people, and there was often a vicious circle of constipation, neurosis, purgation, indigestion, and undernutrition. There was no experimental evidence that chemical or bacterial toxins were absorbed from the colon in intestinal stasis in amounts sufficient to cause symptoms, and many so-called toxic symptoms were the reflex results of distension of the sigmoid and rectum with fæces. Food allergy was very real, but there was danger in too facile diagnosis of it.

Dr. Thomas Hunt said that of 93 cases of simple indigestion without organic lesion, he had been able to place 62 in the category of irritable spastic colon. Even severe cases might show little on X ray examination or by ordinary physical investigation; on the other hand, there might be big displacements with normal function. Certain symptoms aided the differential diagnosis. An increased frequency of discomfort in cold weather, and backache, were both common, as was also aching in the muscles after the passage of mucus. Flatulence was frequent and true aerophagia occurred in 11 of 53 cases; patients often said they had the feeling that defæcation was always incomplete. Frequency of micturition was another symptom, and a full bladder could excite colon spasm, thus accounting for the pain which sometimes awakened a patient at night. There might be loss of weight and vomiting, sometimes severe, and these might be aggravated by injudicious handling from the psychological point of view. Three main points of tenderness were the right iliac fossa (over the cæcum), the epigastrium (over the aorta), and the left iliac fossa (over the sigmoid).

The causes could be considered under four heads: reflex, bacterial, allergic, and nervous. The most important, he thought, were the nervous; even the effects of taking purgatives must be placed second to them. It was possible to exaggerate the importance of bacterial infection, and this had the disadvantage of fixing on patients the idea of a physical illness. Actually a sea voyage with congenial companionship (to take one example) might be far more useful than vaccines and other remedies directed towards the physical condition. Even in the cases attributed to over-use of purgatives there was a strong nervous element; this was shown by the fact that of 75 patients with other than digestive disorders, 37 had been taking purgatives every night for ten years or longer but were not adversely affected. The emotional element could sometimes be greatly reduced by reassurance, explanation, and argument, apart from any intricate psycho-analysis. The most important cause of the trouble was fear. The fear of organic disease was fairly common. At the same time there were other sources of anxiety, associated, for example, with masturbation, sexual frustration, or coitus interruptus. Lack of work and the state of mind it produced could not be ignored.

In treating the unstable colon the diet should be as free as possible, the only restrictions being the exclusion of substances with hard residue, such as nuts and peel. It was desirable to limit the formation of gas in the bowel, and a mixture of belladonna and bromide was often successful, though belladonna had less effect on colon spasm than on pyloric spasm. Sedatives lessened fear and nervous tension. In some cases he had found nitrites of value; amyl nitrite capsules almost always brought temporary relief. He had not seen much effect experimentally from either adrenaline or pilocarpine. In cases of loss of appetite and under-nourishment insulin might be useful, for a gain in body-weight would give valuable encouragement.

Dr. A. F. Hurst said it was important to realise the essential part played by mucus as a lubricant; it was absurd to look upon its presence in the stools as evidence of colitis. Secretion of mucus took place whenever the colon was irritated, and an aperient stimulated secretion in excess; but this excess should not be regarded as evidence of disease unless it was associated with looseness of bowels not caused by aperients. In normal defæcation the whole colon took part, even the cæcum, and most cases of constipation were due to deficiency in the process. Defæcation was a conditioned reflex, initiated when the child was first required to regularly use the chamber; if this reflex was for any reason broken in later life the habit should be re-formed, and this often sufficed to cure the constipation. He considered that there was only one sphincter of the colon—namely, the anal. It was the easiest of the sphincters to get at; it could be easily dilated by the fingers, and in Hirschsprung's disease frequent digital dilatation was often effective without the operation of sympathectomy. Intestinal allergy was rare but very important. Patients with this had a sudden violent colic, with diarrhœa and a feeling of unfitness; they often gave a history of asthma or hay-fever, and the blood always showed eosinophilia during the attack. Adrenaline sometimes cut short the attack. Intestinal flatulence Dr. Hurst attributed to irregularity in the small intestine.

Dr. G. E. Vilvandré spoke of the value of barium meals and barium enemas in disorders of the colon. No barium meal examination was complete, however, unless a radiogram was seen also after defæcation. If organic disease was present there might then be *contraction of the colon.*

Mr. Eardley Holland said that many women with functional disorders of the colon were thought to have gynæcological lesions. Most of the cases of this kind which he saw were the products of some emotional upset. Retroflexion of the uterus was very common indeed, and suspension of the uterus gave the patients hope. Enuresis and dyspareunia also were found in cases with colon disturbance.

Dr. **Campbell McClure** said that some people seemed to have an inborn imbalance of the vagosympathetic system. He had often found tachycardia and similar disturbances in association with colon trouble.

Mr. W. McK. **McCullagh** did not think that uterine retroversion caused intestinal disorders; but a train of symptoms, including indigestion and dyspepsia, might be caused by the pressure of the uterus on the ovaries, and he had seen women cured of indigestion by ventro-suspension.

Dr. C. E. **Newman** said that the emotional element in these cases had formerly been much neglected. When investigating functional disorders of the biliary tract it was borne in upon him how often these patients complained of disorders of the colon. Intolerance of physical cold, pain over the gallbladder region, backache, nausea without vomiting, and respiratory signs, such as sinus arrythmia, were all commonly found. It was important to give due place to vagal action in these cases.

Dr. J. E. A. **Lynham** drew attention to the great variety in colons as revealed by X rays. Patients with undescended cæcum and a rectocæcal appendix showed a peculiar picture of colon upset. They did not have periodical attacks, and they might go on without disturbance for months or years; after which there would be an attack of great pain, with distension and constipation.

Dr. **Hunt**, in reply, said he wished to make it clear that he did not conclude that colon disorder was functional until a thorough examination had been made to exclude organic disease.

EDINBURGH OBSTETRICAL SOCIETY

A meeting of this society was held on March 19th, with Dr. **Oliphant Nicholson**, the president, in the chair.

Contraction of the Uterus

Dr. **Chassar Moir** read a paper entitled Recording the Contractions of the Human Pregnant and Non-pregnant Uterus. His observations were made with three types of apparatus: (1) an intra-uterine bag and recording manometer by which contractions of the puerperal uterus could be recorded; (2) an abdominal apparatus which recorded changes in the shape of the uterus; and (3) an intra-uterine bag which could be used in the non-pregnant uterus. It was found, he said, that suckling usually caused strong contractions of the puerperal uterus to appear. Ergotoxine, ergotamine, and the alleged new alkaloid sensibamine all caused strong contractions of the uterus, but there was a delay of half an hour or more before any effect was seen after intramuscular injection. This lessened their value in post-partum hæmorrhage unless they were combined with a quick acting drug. Histamine was not effective because it had a negligible action on the uterus when it was used in doses small enough to avoid unpleasant flushing effects. Pituitary extract was reliable early in the puerperium, but its action was very erratic after the first week; in the late puerperium it often failed to produce any activity of the uterus. Liquid extract of ergot (B.P. 1914 and also B.P. 1932) had a powerful quick action on the uterus, the effect sometimes appearing in as short a time as four minutes when it was given by mouth. It caused marked spasm of the uterus for an hour or longer, its action being entirely different from that of the ergot alkaloids, and it was this quick acting factor in ergot which led to its use by midwives 200 years ago. Intra-uterine injection of glycerin was not an effective means of causing uterine contractions.

By a double uterine apparatus contractions were simultaneously recorded from fundus and cervix. There was some evidence of a peristaltic wave in the uterus, since the contractions of the cervix lagged about 17 seconds behind those of the fundus. The non-pregnant uterus showed contractions at all periods of the menstrual cycle, but these gradually increased in force from the sixteenth day till the onset of menstruation. During menstruation the contractions exerted a pressure considerably in excess of that seen during parturition. In a case of dysmenorrhœa the intra-uterine pressure rose to surprising heights. Contrary to Knaus's observations published in 1929, it was found that the uterus always responded to pituitary extract. Oxytocin (Pitocin) in doses of 10 units intramuscularly had no effect on the non-pregnant uterus, whereas vasopressin (Pitressin) in the same dose had a very marked effect.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED MARCH 24TH, 1934

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 5 (last week 10); scarlet fever, 3093; diphtheria, 1189; enteric fever, 19; acute pneumonia (primary or influenzal), 1529; puerperal fever, 70; puerperal pyrexia, 110; cerebro-spinal fever, 17; acute poliomyelitis, 5; acute polio-encephalitis, 1; encephalitis lethargica, 4; dysentery, 15; ophthalmia neonatorum, 96. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on April 1st–2nd was as follows: Small-pox, 17 under treatment, 1 under observation (last week 16 and 0 respectively); scarlet fever, 1637; diphtheria, 1803; enteric fever, 7; measles, 3557, (last week 3470); whooping-cough, 325; puerperal fever, 21 mothers (plus 7 babies); encephalitis lethargica, 260; poliomyelitis, 4; "other diseases," 160. At St. Margaret's Hospital there were 19 babies (plus 11 mothers) with ophthalmia neonatorum.

Deaths.—In 118 great towns, including London, there was no death from small-pox, 2 (1) from enteric fever, 187 (82) from measles, 14 (2) from scarlet fever, 37 (9) from whooping-cough. 54 (7) from diphtheria, 58 (23) from diarrhœa and enteritis under two years, and 109 (26) from influenza. The figures in parentheses are those for London itself.

The weekly total of fatal cases of influenza is a little lower, the figures for the last few weeks (working backwards) being as follows: 109, 115, 99, 96, 85, 87, 73. The fatal cases were widely distributed among 49 great towns, the highest number of deaths being reported from Birmingham 10, Leeds, Liverpool, and South Shields each 7, York, Stoke-on-Trent each 3.

There were 16 fatal cases of measles in Liverpool, 12 in Middlesbrough, 10 in West Ham, 4 each in Walthamstow, Salford, and Norwich. Whooping-cough caused 6 deaths in Birmingham, 3 in Liverpool. Seven deaths from diphtheria were reported from Leeds and Liverpool, 4 from West Ham and Birmingham, 3 from East Ham and Hull.

The number of stillbirths notified during the week was 282 (corresponding to a rate of 43 per 1000 total births), including 42 in London.

Lancaster Royal Infirmary.—Last year this hospital derived £1954 from the payments of 149 private patients. There were 1816 in-patients, who stayed on an average 19·14 days, as against the previous year's average of 17·28 days.

REVIEWS AND NOTICES OF BOOKS

Traité de médecine des enfants

Publié sous la direction de P. NOBÉCOURT et L. BABONNEIX. Secrétaires de la Rédaction : J. CATHALA et J. HUTINEL. Paris : Masson et Cie. 1934. Tome I. Pp. 884. Fr.170. Tome II. Pp. 960. Fr.150. Tome III. Pp. 1088. Fr.170.

IT is nearly 25 years since a system of pædiatrics in any way comparable with the present one has appeared in France. These three volumes are the first of five, and the work has been entrusted to over 70 authorities. The first volume begins with a historical review of pædiatrics and pædiatricians from the time of Hippocrates to the present day, and includes such illustrations as the obtaining of asses' milk for artificial feeding, the method of leaving and receiving infants in a foundling institution, and (a more modern touch) a royal visit in 1790 to a ward in a children's hospital. The aims and methods of prophylaxis and treatment are outlined in some detail. The main body of the volume is devoted to a consideration of normal and abnormal growth, development and nutrition, endocrine disorders, congenital abnormalities, and deficiency diseases. The disorders of growth are particularly well illustrated, though a more liberal use of normal controls in the photographs would have made the significance of these more plain. In a work of this scope, a rather fuller discussion of the recent work on the pituitary might perhaps have been usefully included, though the endocrine section otherwise gives a fair presentation of the stage that has been reached by careful clinical rather than experimental observation.

The second volume deals with infectious diseases and diseases of the blood and hæmopoietic system. We note that rheumatism is included without comment amongst the infectious diseases, although the theory of a streptococcal origin is rather summarily dismissed. Those with long memories may echo the author's opening comment : "Il serait vain et peut-être cruel de rappeler tous les germes qui ont été tour à tour décrits dans le rhumatisme articulaire aigu." "Fourth disease" receives full recognition, but (a little in the grand manner) a fifth and sixth disease as well. Congenital syphilis is, as would be expected, fully and admirably discussed, though few British clinicians will accept the attribution to it of such widespread effects ; indeed, those who boggle at inheritance as far as the third generation will be a little staggered by its calm visitation on the children of the fourth and fifth.

Diseases of the cardiovascular and respiratory systems, and the first part of the section devoted to diseases of the alimentary tract, are included in the third volume ; the numerous X ray pictures are well chosen and for the most part well reproduced, though, as is so often the case, those in which lipiodol has been used entirely fail to give adequate contrast in the print. It is perhaps a pity that in view of the value of lipiodol in the diagnosis of pulmonary disease in childhood, and the pioneer work that has been done in France in this field, more space was not devoted to a description of the technique of its injection and to the dangers and difficulties to be avoided in its use. The section on pulmonary tuberculosis in childhood gives an excellent review of the modern conception of the pathology and spread of the disease.

The volumes are beautifully produced and profusely illustrated, but in a work of such dignity more attention should have been paid to the accuracy of the references. A very great number of the English and American proper names are spelt wrongly or inconsistently (in one instance there are four mistakes in five names, and three variations of one name on one page) ; the authors of one section give naked-eye and histological post-mortem findings in a case quoted from the English literature which is, to our certain knowledge, still alive and in excellent health. The work as a whole, however, is a real addition to pædiatric literature, and the appearance of the subsequent volumes will be awaited with keen interest.

Hypnosis and Suggestibility

By CLARK L. HULL, Professor of Psychology, Institute of Human Relations, Yale. London and New York : D. Appleton-Century Company Inc. 1933. Pp. 416. 15s.

Hypnotism—Friend of Man

By J. LOUIS ORTON. London : Thorsons. 1933. Pp. 280. 5s.

Hypnosis and Suggestion

By WILL. F. LOVATT, C.S.M.M.G., B.P.A. London : Rider and Co. 1933. Pp. 144. 2s. 6d.

Hypnotism Explained

By ALAN MACEY, M.D. London : Ferland Press. 1933. Pp. 131. 2s.

HYPNOSIS is not only a therapeutic instrument for treating certain abnormal mental states ; it is still more a mental state, which provides material for investigation not only by the psychologist, but by the neurologist. To the former, it is important in the understanding of suggestion, dissociated mental states, and hysteria. To the latter, it has affinities with narcolepsy, catalepsy, and allied phenomena related to the sleep mechanism and perhaps to the epilepsies.

Dr. Clark Hull's work on hypnosis is of extreme interest as one of the very few attempts that have been made to deal with the phenomena by the controlled methods of experimental psychology. After describing concrete experiments on methods of inducing hypnosis and negative and positive states of suggestibility, he gives details of laboratory experiments which are of great value in illustrating how these illusive and much-distrusted phenomena are accessible to laboratory technique. Post-hypnotic phenomena are carefully studied, and most important is the author's denial of the identity of sleep and hypnosis. Hypnosis as heightened suggestibility is experimentally demonstrated, and such an important topic as non-prestige suggestion is analysed and related to perseveration. No psychopathologist can ignore this carefully planned inquiry.

Beside this treatise the books by Orton and by Lovatt are merely pleasant and popular expositions of hypnosis as universal panaceas. Both are well-endowed practitioners of the art, and Orton in particular writes in a friendly diffused manner which to the suggestible may have quite a hypnotic effect producing perhaps, in consequence, some uncritical enthusiasm.

Dr. Macey provides in small bulk a practical exposition of hypnosis with none of the faults exhibited by those of Orton or Lovatt. It is strictly medical and describes methods of induction and the application of hypnosis to medicine, surgery, and education. The author describes the relation of hypnosis to multiple personality, quoting Morton Prince's case. He omits, however, to discuss this case in the light of general psychopathology. This is indeed an error common in books devoted exclusively to hypnosis as an isolated phenomenon, and generally speaking provides an argument against its separate consideration.

Oxidation-reduction Potentials in Bacteriology and Biochemistry

Second edition. By L. F. HEWITT, Ph.D., B.Sc., A.I.C. Published by the London County Council. 1933. Pp. 81. 2s.

THIS valuable little monograph, the first edition of which was reviewed in our columns three years ago, was published by the London County Council as a combined description of original work carried out in their laboratories, and an introduction to the basic principles involved. The venture has had a gratifying success, which is due to the straightforward manner in which the author has dealt with his intricate subject. In this edition the text has been thoroughly revised, recent work has been included, and the bibliography has been brought up to date. Though no sensational advances are recorded, steady progress has been made. Oxidation-reduction potentials have come to stay in bacteriology and biochemistry, and this little book provides an excellent introduction to this study.

Cutaneous Neoplasms

By C. NORMAN PAUL, M.B., Ch.M., Physician for Diseases of the Skin, Sydney Hospital; Past President, N.S.W. Branch of the British Association of Dermatologists. London: H. K. Lewis and Co., Ltd. 1933. Pp. 153. 10s. 6*d*.

THE prevalence of skin carcinomata and precarcinomatous changes (keratoses on the exposed areas) in the inhabitants of Australia is well known, and has been emphasised by Dr. Paul on more than one occasion in the past. It is equally true that, per contra, lupus and tuberculous infection of the integument is rare, and there is little doubt that the power of the sun is to be blamed for the one and thanked for the other. Dr. Paul takes occasion to warn his compatriots of the dangers incurred by sun-bathing, which, superimposed on the unavoidable exposure, may turn the balance in favour of malignancy at a later date. The warning need not be taken too seriously by sun-worshippers in this country, for to be dangerous exposure must be prolonged and frequently repeated, and the chances of such cumulative effect in our climate, or even in central Europe, are small.

All the commoner tumours, except the nævi, are here considered in detail, and most of them are illustrated by excellent reproductions of photographic studies, together with photomicrographs of sections in the more important group. A section has been devoted to a brief discussion of the seborrhœic and arsenical keratosis, xeroderma pigmentosum, and some of the peculiar abnormalities of the sweat and sebaceous glands, leading to neoplastic—not necessarily malignant—changes. By far the greater portion of the book, however, is concerned with malignant disease in its various forms, the rodent ulcer—or basal-celled carcinoma (both single and the rare multiple types)—the less common squamous varieties, and X ray epitheliomata. Here Dr. Paul's opinions should be read with particular respect, for there is probably no other living dermatologist who has had so extensive an experience. One new departure in treatment will doubtless be tried; for the author claims better results with the consecutive application of radium and CO_2 in certain types of growth—the raised nodular, the ulcerative lesion with raised nodular border, and the superficial with beaded border and cicatrising centre—than with either treatment alone. The freezing precedes the radium application for two or three weeks according to the depth of infiltration, or for so long as shall render the subsequent radium application effective in one session.

It was a good idea to incorporate cutaneous neoplasms in one volume, and the lucid and unpretentious way in which the material is dealt with should make a general appeal.

Food and Character

By LOUIS BERMAN, M.D. London: Methuen and Co., Ltd. 1933. Pp. 384. 8s. 6*d*.

IT is a somewhat humbling reflection that the human belief in magic is such that the last 500 years have simply served to substitute vitamins for mandrakes and gland extracts for love philtres. The title Dr. Berman gives to his first chapter—"Body-mind as a Chemical Brew"—is a good example of the fare his book provides, whilst an introductory cocktail is extracted from the dicta of Henry Ford, Senator Copeland, and others. As there are always a great many people who like to think their food fads are based on the profoundest scientific reasoning (and indeed Dr. Berman handles words like "purins" and "calcium balance" as a master), this book will doubtless appeal to a large public and have an extensive circulation.

A Text-book of Physiology

For Medical Students and Physicians. Twelfth edition, thoroughly revised. By WILLIAM H. HOWELL, Ph.D., M.D., Sc.D., Emeritus Professor of Physiology in the Johns Hopkins University, Baltimore. London and Philadelphia: W. B. Saunders Co., Ltd. 1933. Pp. 1132. 32s. 6*d*.

IN the preface to this book is to be found the sentence "It is doubtless the art of presentation that makes a text-book successful or unsuccessful." Dr. Howell is a master of this art as well as of his subject, and the latest edition of his work is no less attractive than its predecessors. The subject matter is presented in a straightforward way, with great ease of expression; yet no explanation is shirked which is necessary for its proper understanding. The book is not suitable for the advanced student or the research worker, since the author has himself sifted the available facts and theories and has aimed at placing a clear statement before the reader; it is, however, ideal for the student beginning his study of physiology and for anyone who desires a coherent framework on which to build future knowledge, be it on advanced physiology or on medicine. A generous sprinkling of footnote references furnishes jumping-off points for more detailed study if this is desired. The number of pages gives a rather misleading idea of the size of the book, since the print is large and the margins spacious; these features make for ease in reading, however, and the publishers deserve credit for an attractive production.

The arrangement of material is unlike that usually found in English text-books, the central nervous system and special senses being treated in early sections; the former is well done, but is still dominated by the anatomical tradition. That the interests of the student are given first place is emphasised in the section on blood, where the subject of coagulation is dealt with lucidly; the author's own theories are not stressed at the expense of others. Digestion comes rather late in the book, and is described with a minimum of chemistry; much that often precedes digestion is discussed later in relation to kidney excretion, nutrition, and heat production, while the classification of proteins and a certain amount of physical chemistry are relegated to the appendix. This method has advantages from the point of view of interest and perspective, but the student who is a little weak in his preliminary sciences would probably appreciate an enlargement of the appendix to include at least the chemistry of carbohydrates and fats. A reference section of this sort would be extremely valuable, even at the risk of repetition, and would justify the fundamentally sound arrangement which has been adopted. Throughout the book, wherever there is danger of confusion of issues, a historical survey has been inserted, which makes clear at least the evolution of the subject. For the most part the illustrations have been carefully chosen, so that each has an unmistakable significance; they include a few very good colour plates.

Over den Oorsprong der Syphilis

By W. F. R. ESSED. Amsterdam: H. J. Paris. 1933. Pp. 328.

THE title of this book is somewhat misleading, for only a very small fraction of its space is devoted to the origin of syphilis. The author holds that the disease "has always been known in Europe." The evidence for this statement is not given in detail, but is summarised in the sentence: "The recognition by various ancient writers of condylomata lata as an infective lesion of the genitalia and anus, Hippocrates' description of the combination of perforated palate and saddle-nose, and the existence of pre-Columbian bones showing gummatous osteomyelitis are facts which cannot be explained away." The general consensus of informed opinion at the present day is opposed to the pre-Columbian existence of syphilis in Europe. The evidence on the other side has been well summarised by W. A. Pusey in his book "The History and Epidemiology of Syphilis," recently reviewed in these columns.

The bulk of the book consists in an attempt to show that the "new sickness" which was brought into Europe by Columbus' seamen on their return from Haiti in 1493, which within the next few years devastated Western Europe and to which Fracastor in 1530 gave the name of syphilis, was in fact not syphilis at all but frambœsia. The author lays stress on the clinical resemblances between the new sickness, or morbus gallicus, and yaws; on the similarity of the native names for yaws, in different parts of the world at the present day, to the names given to the "new sickness"; and on the differences between the latter and syphilis as now seen. The most interesting part of the book is the full description, compiled from contemporary sources, of the clinical characters of the "new sickness." The book would be improved by the addition of an index and by the arrangement of the extensive bibliography on some systematic plan.

HEALTH OF THE NAVY IN 1932

THE year was a healthy one in the Navy[1]; new cases of illness and daily sick were both less than in previous years. Accident was the chief cause of death, and the rate was substantially raised by the loss of 57 lives in Submarine M2; allowing for this, the death-rate of Army and Navy is almost identical—viz., 2·53. Fatal injuries (apart from the M2 disaster) numbered 66, suicide 14. From disease the death-rate was 1·57 per 1000, the chief contributants being pneumonia 18, pulmonary tubercle 12, malignant new growths 10. On the other hand losses by invaliding were greater by 112; pulmonary tubercle 194 (30 plus), sequelæ of gonorrhœa 32 (22 plus), "other nervous diseases" 73 (30 plus), mental instability 38 (21 plus). One of the 12 cases of enteric fever ended fatally; it is not quite clear from the report when preventive inoculation was given.

Malaria has slightly decreased; the majority of new cases were benign tertian, but in Africa only malignant tertian were seen. Prophylaxis by quinine is touched on: the men of *Delphinium* all took quinine and none got malaria, but the report gives no clue to the degree of exposure. Influenza was light; cases chiefly occurred at home. There were 6 deaths among 43 cases of meningococcal infection; deaths were halved though cases had increased. Some credit for this result is given to frequent lumbar puncture combined with glucose per rectum and much liquid by the mouth. Intrathecal injection of serum was continued until the cerebro-spinal fluid became clear, serum being also given intravenously (up to 40 c.cm. daily) if there was a rash. The incidence of pulmonary tuberculosis has increased from 2·05 to 2·47 per 1000, the highest rates being found on destroyer and submarine depôt ships, but the numbers are too small to draw deductions. It is however noteworthy that the incidence of tubercle in the Navy is double that in the Army or the Air Force at almost every age, a fact worthy of study by the Joint Medical Services Committee which is now in being. Undulant fever is raising its head again at Malta. Venereal diseases are no worse—syphilis slightly up, gonorrhœa slightly down—but, as we have seen, rather more invaliding for sequelæ of gonorrhœa. The prevalence of tonsillitis in Army and Navy is almost equal, but catarrh is almost three times as frequent as in the Navy. Scarlet fever in *St. Vincent* has been again halved by Dick testing and active immunisation. Of diphtheria there were 18 cases in Greenwich Hospital School, only four of which were clinically recognisable. Among the other diseases caused by infection were a fatal case of anthrax meningitis in England, and one of glanders in a Somali from the Red Sea.

Two cases of gastric ulcer, operated upon on the fifth and sixth days, made good recoveries without drainage. Antigonococcus vaccine was used with good results in chronic cases and in others with metastatic sequelæ. An artificer apprentice was found with dextrocardia, but in perfect health. An infra-red generator has been installed at Chatham, and has been usefully employed in obtaining deep hyperæmia. Eight cases of acute appendicitis and one of perforated duodenal ulcer were operated on successfully in ships at sea. Only eight men were invalided refusing operation, showing an increasing confidence of the service in its medical staff.

THE LANCET

LONDON: SATURDAY, APRIL 7, 1934

INCREASING CARE OF THE BLIND

THE Ministry of Health has done well to publish a revised edition of the handbook on the welfare of the blind compiled by its advisory committee.[1] The book is based on the definition of blindness adopted for the purposes of the Blind Persons Act of 1920; it deals with the register of blind persons which every county and borough council in England and Wales is under the obligation of keeping, and with the methods of certification for the purposes of these registers. It sets out the welfare services that have been established for the employable blind by way of training and augmentation of wages earned when trained; and for the unemployable blind, unfortunately in the majority, by means of Braille teaching and home visiting, including the measures to be taken to prevent any blind person from falling into destitution. A growing number of authorities are laying down a scale up to which the income of each unemployable blind person should be brought, and have voted substantial sums to assist the funds of voluntary agencies in meeting these payments. The first difficulty that arises in implementing this measure is on the definition of blindness. There are still two statutory definitions. One, for purposes of the Education Act, runs: "Too blind to be able to read the ordinary school books used by children"; the other, for purposes of registration and eligibility for certain privileges, including the old-age pension at 50, runs: "So blind as to be unable to perform any work for which eyesight is essential." In interpreting the latter definition certain rules have been laid down by the Ministry of Health for the guidance of the certifying surgeon. The main difficulty is to decide whether or not a person having visual acuity between 3/60 and 6/60, with full or nearly full fields of vision, is or is not blind within the meaning of the Act. There are a considerable number of these borderland cases, and some latitude is necessarily given to the certifying surgeon, certain points being laid down for his guidance. Cases with visual acuity between 3/60 and 6/60 should, if there is no material contraction of the field, not as a rule be certified as blind. If however there is a material restriction of the field they should. Does this mean that when one eye is blind or excised and the other sees, say, 5/60 with full field the case should not be certified? Here there is necessarily a restriction of the binocular field of vision, and probably many cases of this type are certified. The certifying surgeon is also told that he can take into account the age at which the defect of sight was first noticed and the age of the patient. Young persons can adapt themselves more readily than old to new conditions, and a man whose defect is recent is less likely to be able to adapt himself to any sighted work than one whose defect is of long standing. The problem of the partially sighted, such as some of those indicated above, does not come within the scope of this handbook, but until there is some consensus of opinion as to what should be done with them and how to help them there will always be the tendency to deal leniently with them in certification. This specially applies to those partially blind persons who, having been educated at a blind school and received a vocational training fitting them to earn their own living partially as subsidised workers under the Blind Persons Act, would yet be quite unable to support themselves without such aid.

All the 146 councils of counties and county boroughs in England and Wales have now made schemes under the Act. The first matter for which these schemes make provision is registration. At present this must be very incomplete. For instance, in 1932 the number of registered blind persons was 59,788. Of these the number under 5 years old was only 225, whereas the number between 5 and 16 was 2066. Now blindness which first becomes manifest during school age is rare, and it is probable that the great majority of the 2000 registered during school age were cases of blindness either congenital or occurring during infancy. It is true that blindness due to ophthalmia neonatorum, which used to be the most important cause in infancy, has very markedly diminished, but this is not the case with blindness due to various congenital malformations, such as congenital cataract, which form a large proportion of the whole. The fact probably is that the majority of cases of infantile blindness do not come to the notice of public authorities until they are of school age. Blind children of school age may be, and for the most part are, sent to day or residential schools at the cost of the local education authority, and are kept there until the age of 16. For high myopes and other children who are partially blind special schools and classes have been organised in London and some other centres, but most country children of this class are either accepted in a blind school or take their chance in an ordinary one. There are not enough of these special classes for the partially sighted. When a blind person is trainable for remunerative employment the Act provides that the local education authority shall secure adequate and suitable provision for this. Actually, this duty is discharged by subsidising voluntary agencies. When the blind worker is trained he becomes "employable." In March, 1932, there were 3342 blind persons employed in workshops for the blind, 1631 in home-workers' schemes, and 4151 others who were employed elsewhere. In order that the blind may earn a living wage it is, as a rule, necessary to "augment" their earnings, and it is also necessary to organise the sale of the goods they produce. A large number of home workers are piano tuners. In order to ensure a proper standard of efficiency in these an examination has been instituted by the Board of Education, and it is their aim that no one who has not passed it should in future be recognised as a home worker.

---

[1] H.M. Stationery Office, 1934, 1s.

While schemes of employment concern a considerable portion of those who become blind in early life, a large majority of the rest are unemployable—77 per cent. of the total on the register. According to their individual circumstances domiciliary assistance is arranged. The Ministry of Health has laid it down that it is an essential part of the duty of the local authority to secure that "reasonable provision" shall be made for these persons, either by their own officers, by voluntary agencies, or by the public assistance committees. The number of "home teachers" whose functions include the teaching of Braille or Moon type and pastime occupation has more than trebled since 1919, being 85 men and 325 women in 1932. It is now a condition of approval that they should obtain the home teaching certificate of the College of Teachers of the Blind within two years of appointment. The actual work of organising these services is generally delegated to voluntary associations, of which there is a great variety, providing for technical training, workshops and home workers' schemes, and a number of home teaching societies, these latter especially for the unemployable blind. The voluntary agencies are for the most part organised in counties and groups of counties. Nearly all have united to form the Union of Counties Associations for the Blind. There are also three important organisations whose work is of a national character—the National Institute for the Blind, the National Library for the Blind, and St. Dunstan's.

MASTOPATHIA AND CHRONIC MASTITIS

FACED by the frequent introduction of new terms for disease, it is well to recall MCFARLAND's dictum that pathology must remain confused both in theory and in application unless its terminology is so relieved of ambiguity as to be easily understood. No more obvious failure in this respect could be cited than the redundant terminology of mammary lesions, and especially of the condition commonly called chronic mastitis. A vast literature has collected round this disease, but its nature and significance are still matters of controversy. Some regard it as essentially "a productive inflammatory process," and lay stress on its benign character as evidenced by resolution following non-surgical treatment. Others, and they are the majority, are suspicious of its possible outcome, since records point to its frequent association with malignant development. Much of this uncertainty has arisen, not because of its possibly inflammatory nature—a conception now generally discarded—but because, while the term conveys a fairly definite idea to the clinician, it embraces for the pathologist almost any abnormality in the breast which is neither an acute infection nor a true neoplasm, and also covers various types of hyperplasia which indicate excessive but more or less physiological functional activity, as well as later involutional changes. The term is therefore indefinite and unsatisfactory, and many attempts have been made to find a substitute. SEMB's suggestion, fibro-adenomatosis (simplex or cystica), has not received in this country the attention it deserves; he assumes the underlying identity of the varied types of the disease, glandular, interstitial and cystic, and describes in a logical sequence various degrees of hyperplasia and cyst-formation and their association with other mammary lesions. LENTHAL CHEATLE and CUTLER separate two distinct proliferative conditions, "mazoplasia," described as an exaggeration of physiological activity with epithelial desquamation, spontaneous disappearance at the menopause, and no tendency to neoplasia, and "cystiphorus hyperplasia," a pathological activity with possible outcome in malignant growth.

In a study of mammary enlargement and its symptoms Prof. BECKWITH WHITEHOUSE[1] questions whether these two conditions should be separated, since he has found them very commonly associated in the same organ. He considers that interpretation of microscopical appearances in the breast needs the correlation of cytology with the phase of the menstrual cycle and its possible abnormalities, for while mazoplasia appears to be the result of excessive mammary stimulation by the corpus luteum hormone and subsequent failure of return to the physiological base-line, cystic disease is, in his opinion, the product of similar repeated excessive stimulations, with a breakdown in the balance between secretion and absorption. This may be an explanation, on the functional side, of the progressive cystic enlargement described by SEMB in fibro-adenomatosis cystica. The mammary disturbance is associated, in 70 per cent. of WHITEHOUSE's cases, with oligomenorrhœa, menstrual headache, and mammary pain with swelling—a syndrome ascribed to excessive formation of luteal hormone as a result of over-stimulation by the anterior lobe of the pituitary. For this disorder, on the analogy of metropathia, he suggests the name "mastopathia" and the final rejection of "chronic mastitis." Rational treatment of this functional upset would seem to be inhibition of the hypophysis. Prof. WHITEHOUSE pays a tribute to CUTLER's success with Ovarian Residue and records improvement in his own cases with theelin (œstrin), though in both series the numbers so far are very small.

An estimate of the permanent efficacy of therapy along these lines cannot be made until we have news of the eventual outcome in such cases. Meanwhile it appears that mammary hyperplasia still needs elucidation. Though different types of proliferative activity are observed in the same mammary tissue, their identity as phases in a progressive process cannot be assumed and ascribed to the same functional upset. In "chronic mastitis" two types of epithelial proliferation are usually observed: the one an excessive glandular formation of physiological type, or "adenosis," and the other what WHITEHOUSE calls excessive epithelialisation, preferably "epitheliosis," of individual glandular structures. Adenosis is often associated with puberty and adult mammary enlargement and underlies many temporary menopausal swellings; it may result in fibro-adenomatous tumours, but has apparently no connexion with malignant development. Epitheliosis, on the other hand, is a suspected condition, for though many of the cysts formed by proliferation in the glandular structures become atrophic and permanently quiescent, as in the blue-domed type described by Bloodgood, we have at present no means of determining in situ the final result of cystic activity. We are in fact faced here by the possibly "precancerous" lesion met with in other tissues. The wide divergence of clinical and pathological findings which have been recorded is evidence that the clinician has inadequate guidance in the treatment of these breast conditions, and suggests that further investigation is needed to throw light on the difficult problems of mammary hyperplasia.

LONG LIFE

Common observation suggests that longevity runs in families. Most people could call to mind a family whose members had all reached an age well beyond the Psalmist's allotted span, or (perhaps less readily) one whose members had all died relatively early in life. The drawback to this kind of evidence is that such individual pedigrees may be no more than curiosities; everyday observation tends to put undue emphasis on the extremes and to disregard the normal or average. A family of four, all of whom live to be over 80, is noteworthy and the circumstance is easily remembered, whereas a family of four dying at ages 25, 45, 65, and 80 will attract no corresponding attention. To measure the force of heredity we need a large and unbiased sample of family histories, and so far the material available for study has been somewhat inadequate, being limited to data such as those provided by the peerage, the records of the Society of Friends, and the histories of notable persons and families individually recorded. At first thought it might seem that insurance companies must possess the information required; for an assessment of the weight to be assigned to family history in the prognosis of longevity is of obvious importance to those who sell assurance policies upon lives. A little consideration leads, however, to the conclusion that information provided by the applicant for insurance is useless for the purpose. One flaw is that the age of the parent at death is known in the society's records only if the parent is dead at the time the application for insurance is made. This age is not known if the parent dies after acceptance of the proposed policy-holder. In other words, short-lived parents would be in excess and long-lived parents in defect, since many assurances are effected in early adult life. The second flaw is that "bad" lives do not apply for assurance or on application are rejected, so that those accepted are a physically select group. This explains why workers have fallen back upon the recorded family histories of special social classes. And in these groups a significant, though small, correlation has been found between the length of life of parent and child, and between brother and brother.[1]

In a series of studies on human longevity which is being carried out in the department of biology of the school of hygiene and public health of the Johns Hopkins University, Prof. Raymond Pearl (in conjunction with Miss Ruth Pearl) has approached the subject from a somewhat different angle.[2] By the questionnaire method they have acquired case-histories of 1579 persons living at the ages of 90 years and above, and from these have chosen a group of 365 who could give particulars of the age at death of both parents and all four grandparents. For comparison similar data were extracted from family records already in possession of Prof. Pearl's department. Analysis of this material showed that the average length of life of the six immediate ancestors (taken as a whole) was nearly 16 per cent. greater in the case of the nonagenarians and centenarians than in the comparative group. In addition the average age at death of each one of their six ancestors was substantially higher than that of the corresponding ancestor in the comparative group—a 20–30 per cent. advantage in the case of parents and 10–14 per cent. in the case of grandparents. It was noted, however, that as large a proportion as 13·4 per cent. of the nonagenarian and centenarian group was derived from matings in which *neither* parent was long-lived (long-lived being defined as 70 years or over at death), so that it appears that extremely longevous persons may be bred from short-lived or average ancestry in a small but not negligible proportion. But it may be observed that 45·8 per cent. of the nonagenarians and centenarians, 56·7 per cent. of their fathers, and 53·4 per cent. of their mothers had *both* their parents in the long-lived category, contrasted with 11·9, 37·1, and 30·1 per cent. in the comparative series. A striking difference was also found in the infant mortality-rates; in the long-lived families it was only 59 per 1000, compared with 125 in the life table population of 1901, and 144 in the comparative series. Generally, therefore, these long-lived have kin whose vitality is superior to the average.

To accept these relatively large differences in the duration of life lived by the immediate ancestors, and the sibships, as being due only or mainly to hereditary influences, one must infer that the environmental conditions in the two series of families do not on the average differ significantly—that the long-lived families do not share a common environment superior to that of the comparative series. How far this is true it is impossible to determine. The long-lived persons are, the report points out, not a random sample of longevous persons generally. They are those "whose great age *per se*, or something they did, or that happened to them, caused them to be written about in their local newspapers." A notably long-lived kinship or ancestry might be a factor tending to bring them into the public eye, and this would introduce a bias to the series. Such points make it difficult to exclude completely environmental and selective factors, but in general this interesting study adds to the cumulatively convincing evidence in support of hereditary factors in the duration of life. We still lack an adequate measure of the strength of these factors and evidence as to the mechanism of such inheritance.

DINITROPHENOL COMPOUNDS IN OBESITY

During the last two years drugs of the nitrophenol group have been widely used in the treatment of obesity, and it may now be opportune to take stock of the experience gained on both sides of the Atlantic. It is clear that the nitrated phenols are powerful and hence potentially dangerous agents, their principal effect being a substantial acceleration of the basal metabolic rate. Three deaths have so far been recorded, for which dinitrophenol was responsible in two and dinitrocresol in the third. The first fatality followed an enormous overdose taken, it seems, intentionally (J. C. Geiger [1]); the second occurred in a negress who received rather large daily doses of nitrophenol over a period of two weeks [2]; while the third, which formed the subject of a recent coroner's inquest in London, can also be attributed to overdosage for which the patient was responsible. Apart from these deaths there is ample evidence that more or less serious toxic symptoms are not uncommon. Some of this evidence has already been mentioned in these columns,[3] and further instances have more recently been described by J. H. Masserman and H. Goldsmith,[2] who observed unpleasant reactions, notably a fall in blood pressure, tachycardia, acidosis, and stupor in 4 out of 18 psychotic patients treated with dinitrophenol. Such drawbacks, however strongly they may argue in favour of caution and rigid control of the sale of the drugs, do not necessarily provide reason for discarding them, for, as I. M. Rabinowitch and A. F. Fowler [4] point out, some of the most useful drugs in the pharmacopœia, such as morphia and strychnine, are equally open to abuse. But this argument can be pushed too far. The first care of the physician is to do no harm to his patient. He does not prescribe morphia when aspirin will answer his purpose; neither should he use dinitrophenol until he is satisfied that safer remedies are not available. This elementary principle of therapeutics seems in danger of being overlooked.

It might be expected, with reason, that a drug which stimulates metabolism would be valuable mainly in treating conditions in which metabolism is depressed. The clearest example of such an abnormality is myxœdema, but myxœdema is more than a simple expression of slowed metabolism (Dodds and Robertson,[5] D. M. Dunlop [6]), and incidentally is *not* generally associated with conspicuous adiposity; so that nitrophenol is useless as a substitute for thyroxine. In the vast majority of cases of obesity the basal metabolic rate lies within normal limits and the excess fat must in theory, and can in practice, be readily dispersed by simple restriction of diet and increased physical activity. It is true that nitrophenol by raising the basal metabolism will increase the total output of heat from the body and will so permit the self-indulgent to eat their cakes while preserving their figures. But this entails habitual use of the drug; and he would be a bold man who, mindful of what was learnt about nitrated aromatic compounds during the war, would ignore the possibility of ultimate damage to the liver.

To revert to more immediate dangers, two facts may be emphasised: the first that, short of periodic measurements of basal metabolism, which are rarely practicable, there is no way of recognising intoxication from overdosage or idiosyncrasy in good time; and the second that, once the metabolic fire has got out of control, the physician is helpless, for as yet he has nothing with which to quench the flames. The question may be fairly stated thus: is it justifiable, in dealing with a condition which almost always responds readily to a little wholesome discipline, to employ instead a drug of unquestioned potency but uncertain toxicity?

ANNOTATIONS

COMPULSORY CONSULTATIONS

The March number of *St. Bartholomew's Hospital Journal* contains a rumour that the medical consultations held at the hospital are to be abolished. Let them pass, the surgeon might say, for they are only things of yesterday, mere mushroom growths. The old-time physicians rarely saw the patient; they prescribed for him sitting in a coffee house, upon the report of symptoms told them by the apothecary. They were far too individualistic to consult with anyone, least of all with a fellow physician, unless a great nobleman had the gout or a royal personage was about to die. It was far otherwise with the surgeons.

From the earliest times of which there is any record in London the surgeons were the guardians of the public health and were held responsible for the cure of the sick and maimed. They were on duty at the city gates to see that no grossly diseased person was admitted; and as early as Feb. 2nd, 1369, the chief officers of their gild were sworn to take charge of the hurt and wounded and to give true information to the officers of the city about such persons "whether they be in danger of death or not." A few years later when the barbers had become a company they ordained, in what would now be called their standing orders, that "no barber practising the surgical faculty within the liberty of the city should presume to take under his charge any sick person in actual danger of death or of permanent disability from injury without showing him to the master and wardens." Should he fail to make such a presentation within three days of the patient coming under his care the barber so offending was to pay a penalty of 6*s.* 8*d.* for each day, 5*s.* to go to the chamber at the Gildhall and 1*s.* 8*d.* to the use of the Barbers Company. The master and wardens were to give their advice free, but if the friends of the patient insisted upon making a present "it be evermore divided by the master into even portions under the penalty of a fine of 20*s.*" Moreover, "if they do deny or make refusal to go when so called they equally to pay 20*s.*"

This presentation of the sick and maimed served two purposes. It ensured that the patient was seen by three surgeons of great experience, and it shielded the practitioner in attendance from any subsequent action for neglect or malpractice. Neither was it very arduous. London was a small place in the sixteenth and seventeenth centuries and every part of the city was within a few minutes' walking distance. The system worked well, for there is no record of the master and wardens abusing their privilege; but there are countless instances of shifty and ignorant practitioners being fined for neglecting their duty. The utility of the regulation was so plain that it was adopted by other towns like Newcastle-upon-Tyne, York, and Bristol, where the barber surgeons had formed themselves into a company. In London it fell into disuse after 1745 when the surgeons separated from the barbers, but the shadow of it remained in the newly formed voluntary hospitals and infirmaries. It was customary, even within living memory, to advise every member of the surgical staff when an operation was to be performed, naming the day and hour. They attended, watched, advised, and, when an emergency occurred, assisted. Even at such well-regulated hospitals as St. Bartholomew's, St. Thomas's, and Guy's the comments of the onlooking surgeons were sometimes caustic, and a reputation could be easily lost or won.

Surgical consultations as they now exist are purely educational. They are a feature of Basle and some other continental clinics where the pathologist discusses with the surgeons concerned the post-mortem findings of the week. They have long been a feature at St. Bartholomew's Hospital, and in a modified form they are in use at the Peter Bent Brigham Hospital at Boston, Mass. At St. Bart.'s surgical consultations began at some time between 1850 and 1860, possibly at the instigation of Sir James Paget, who was always solicitous for the improved teaching of medical students. They are still conducted periodically in the manner in which they began, except that they are now held in a special room instead of, as formerly, in the (only) operating theatre. Punctually at half past one on a Thursday afternoon the surgeons and assistant surgeons assemble and with them a crowd of students. A patient is brought in about whose treatment his surgeon has doubts, or who is suffering from a condition which is interesting on account of its rarity or obscurity. The nature of the case is explained in the presence of the patient, who feels thereby honoured above his fellows. Each member of the surgical staff examines and puts such questions as he thinks necessary and the patient is then wheeled back to his ward. Each surgeon in the order of seniority expresses his views and the surgeon in charge of the case sums up. At Boston the method varies somewhat, for it is based on continental lines. Once a week the physicians and surgeons assemble and the amphitheatre is filled with students. The clinical notes of patients who have died are read out; staff and students alike make a diagnosis from the recorded facts. The pathologist then steps forward and records the post-mortem findings. His statements are sometimes surprising but chastening to self-confidence.

AMŒBIC DYSENTERY AND FOOD-HANDLERS

APPENDED to a paper[1] by those responsible for the public health of Chicago is the report of a strong committee appointed to investigate the outbreak of dysentery in that city last year.[2] This committee is convinced from clinical and post-mortem findings that the infection was without question amœbic. Two hotels were concerned, and as soon as the dysentery was reported from city hospitals steps were taken to examine their food-handlers. This investigation disclosed 15 clinical cases and 11 carriers of *Entamœba histolytica*. Since exclusion of carriers from food service had apparently been successful in bringing to an end a similar outbreak in Chicago in 1926–27, it was again brought into effect. But it did not check the new epidemic and a second survey, financed by the hotels in question, showed that the personnel other than food-handlers was widely infected. Accordingly the sanitary equipment of the hotels was investigated. The height of both is too great for all floors to be reached at the pressure of the city's water-supply, and the upper floors have to be served by means of pumps situated in the basement of one of them; they have thus a common feature in their water-supply. Further, they had in common special risks of three kinds. The lay-out of the water and sewerage systems was typical of that of older buildings in Chicago in that there was a possibility of back syphonage from water-closets into water pipes. Moreover, twice within three days in the summer of 1933 heavy rain flooded the basement with diluted sewage, entering an ice-storage room, which it filled to the ceiling, and covering the floor of much of the area where food was handled. Finally there were cross connexions of serious character between water and sewage lines, or between water lines carrying potable water and water potentially subject to contamination. These grave defects were put right as soon as discovered, but up to January of this year there had been over 700 clinical cases of amœbic dysentery distributed over 206 cities, and over 1000 carriers had been recognised in Chicago alone.

The direct issue here has turned out to be one of engineering and plumbing and not of food-handling, for food-handlers were conspicuous victims and not originators of the epidemic. Nevertheless, the committee has rightly raised the question of carriers and food-handling. It holds that no one passing cysts should be allowed to hold that occupation until, seven days after treatment, there have been three negative stool examinations, at intervals of at least one day, and at least four more at intervals of a month. A. Bassler[3] believes that to ensure a parasite-free condition at least three fæcal specimens should be examined three-monthly for a year. Much, however, depends on the method of examination. By a thorough survey of 55 persons in a mental hospital in Sweden, Ruth Svensson and J. F. Linders[4] have compared three methods of diagnosis: at least six smears from formed stools, a single smear from a loose stool, and culture from the latter. They found that, of all infections so discovered, 73 per cent. were detected by the first, 75 by the second, and 94 by the third. In the most conspicuous failure of the first, 13 examinations failed to detect amœbæ, whereas a single examination from a loose stool disclosed them. The Dobell-Laidlaw culture medium was used with added starch and trypaflavine, the Boeck-Debohlav medium disclosing only 61 per cent. of cases. Svensson and Linders lay stress on the observation that the ease with which infection can be demonstrated depends on the tendency to encyst, and that for *E. histolytica* at least three factors govern this—the host, the food of the protozoon, and concomitant bacterial flora. It may differ greatly again in different groups of persons.

It is clear that the tracking down of all carriers among food-handlers is no easy matter, and that there is considerable room for improvement in technique.

TREATMENT OF LEPROSY TO-DAY

IN a review[1] of the treatment of leprosy Dr. Ernest Muir points out that, as no specific remedy is yet available, each writer is guided by his own experience and preference, with the result that the number of methods employed is very large. They range from autogenous and stock vaccines and other protein substances, through the various chaulmoogra compounds, iodides, heavy metals, and a wide variety of irritant drugs, to cauterisation and electrotherapy. Spontaneous recovery is not unknown, and severe infections such as kala-azar and pneumonia have been known to produce surprising improvement, presumably through their general shock effect. Dr. Muir declares that the best results are obtained by raising the patient's general health and resistance to the highest possible level and giving the maximum amount of the most effective special treatment consistent with maintaining the general health. He regards it as important to have a trustworthy means of estimating the patient's resistance. It is, he thinks, a mistake to press the special treatment until a general reaction is produced. The appearance and feeling of the patient are useful, but a patient whose general health is good might still suffer from a lepra reaction. The erythrocyte sedimentation test is invaluable; anything which accelerates sedimentation lowers the resistance to leprosy. When sedimentation is fast it is necessary to proceed with caution and build up the general health; when it is slow the special treatment may be pressed with confidence. Complicating diseases such as malaria, dysentery, venereal disease, pyorrhœa, and other infections and infestations should be corrected as far as possible. To move the patient to a cooler climate is sometimes useful, and a well-balanced diet is essential. The patient should have a regulated daily time-table, with suitable mental and physical occupation to prevent brooding and depression. Physical training should be progressive and include special exercises to correct trophic pareses and deformities.

When the time has come to initiate special treatment, Dr. Muir is insistent on caution, for almost any effective remedy has a depressing effect. The first dose must be tentative, the second should be given only after the negative phase of the first has passed off, and the dosage is gradually raised until the limit of tolerance is reached. This limit may be extended by use. Potassium iodide is considered by most workers too dangerous for general use; the oils appear to give the best results, and of these chaulmoogra or hydnocarpus holds first place. Sodium hydnocarpate or alepol, although less effective than the oil and the esters, has the advantage of being compact and easily preserved. The best method of administration seems to be intradermal infiltration. Oil made from ripe fresh seeds causes little irritation, but, owing to its viscosity, it does not penetrate the intercellular spaces as readily as the esters; this difficulty may, it seems, be overcome if it is heated on a water-bath to 55° C. Oil is much cheaper than the esters and a uniform quality can be more easily secured. The difference in efficacy between the two is not great. The greatest difficulty in treatment is of course the length of time required—three to five years on an average. Good results are impossible without the intelligent and willing coöperation of the patient, and even then the patient should report at frequent intervals for a number of years.

CUTANEOUS MOLES

PIGMENTED moles, or melanomata of the skin, are equally common in the two sexes and very widely distributed. Indeed, there are very few people who cannot show a few small flat brown or black spots somewhere on their bodies, and there is seldom any objection to their appearance. Removal is sometimes demanded, nevertheless, for cosmetic reasons, and provided the lesions are not counted in scores or hundreds it may well be practicable. When undertaken, however, it must be drastic; there must be no tentative applications of caustics, radium, or X rays. The best weapon of attack upon the pin-point to the pea-sized lesion, whether hairy or not, is almost certainly the electrolytic needle. It is very doubtful indeed if the more modern diathermy point offers any advantages over this older method, and in unskilled hands it is liable to cause deep burns and scars.

From the strictly medical standpoint pigmented moles have a more serious importance in view of their occasional (fortunately very rare) tendency to undergo malignant degeneration with metastasis. T. Butterworth and J. V. Clauder,[1] from a review of 500 published cases, are able to give some account of the circumstances under which this degeneration takes place. In 10 of 50 cases of their own it appeared that trauma had a part in causing the change, and to put the proportion of traumatic cases at 20 per cent. is not excessive in the light of observations by others whom they quote. In practice we may say that the slightest change in the appearance of a pigmented mole, whether flat, raised, nodular, or hairy, papillomatous or verrucose, should indicate removal without delay, and by the diathermic method for preference. Probably the most convenient applicator of this "cold cautery" is the snare, which resembles in size and shape that used for removing polypi from the nose. In the frankly malignant cases, it is suggested, a margin of healthy tissue, 3 cm. wide, should be removed at the same time, and this seems advisable even where malignancy is doubtful. The excision should be carried deep enough to include the fascia covering the muscles. Butterworth and Clauder recommend that deep X ray therapy should follow, but do not say whether the diathermy wound should be sutured or not. There should be no objection to an attempt at suture if the wound is free from sepsis at the time of the operation, and not too wide for the edges to come together without plastic procedures which would open fascial planes and increase the risk of spread. The subsequent irradiation, it is proposed, should include the area of lymphatic drainage and the lymph glands associated, and thus far there would probably be complete agreement; but most authorities would be inclined to criticise Butterworth and Clauder's view that the dissection and removal of regional glands is of doubtful value. In the disseminated case such a measure would of course be useless, but in an early case or one of doubtful malignancy most surgeons would advise it. One point cannot be stressed too strongly: the scalpel should never be used to remove the tumour. Furthermore, X rays should not be applied until after its removal, since generalisation, with melanin in the urine, has been observed to follow rapidly in more than one case.

[1] Jour. Amer. Med. Assoc., March 10th, 1934, p. 739.

The prognosis is worse perhaps in cases of cancerous mole than in any other form of malignant disease, and it is of vital importance to deal with them in their very early stages. By way of prevention it may be said that any pigmented mole which is situated in an area liable to constant slight trauma or irritation should be removed—e.g., on the foot where covered by the shoe, under a truss, on the face when a razor may damage it daily, and under corsets or braces. A mole that is changing its appearance, colour, or size should be removed by diathermy, and the dissection of regional glands should be considered. Caustics must never be used, and even electrolysis is permissible only for such small lesions as can be wholly destroyed at one sitting.

INOCULATION OF LIVING SPIROCHÆTES IN SYPHILIS

THE success achieved in most of the stages of syphilis by the chemotherapeutic methods at present in vogue has overshadowed the possibilities of specific immunisation. A practical obstacle to vaccine treatment has been the difficulty of cultivating the spirochæte in adequate purity and profusion, but this, it is stated, has been overcome by Hilgermann, who has also found means of reducing the pathogenicity of the living organisms. For some considerable time the dermatological and neurological departments of the University of Debrecen in Hungary have had supplies of an "avirulent" living vaccine, and Prof. E. Neuber[1] is able to report on its clinical use. It has not, for obvious reasons, been injected into uninfected subjects; nor is any mention made of its trial upon animals. Of the 215 syphilitic patients treated 42 received vaccine alone for six weeks, followed by bismuth and arsenical combinations. In the other 173 cases the vaccine and chemotherapy were combined from the first; on the average three or four injections of material, in quantity decreasing from 1·0 to 0·1 c.cm., were given, for the most part subcutaneously. Local reactions resembling those produced by injections of tuberculin were common, especially after the earlier and larger injections, and in 62 cases there was a general reaction, with fever, headache, and malaise. The Wassermann reactions became somewhat more pronounced under vaccine treatment, and it was noted that a series of cases treated in the ordinary way—i.e., without vaccines—attained a negative serum more rapidly than those subjected to the combined injections. In the 42 cases treated with vaccines alone (three injections with a fortnight's interval between each) the clinical manifestations were sometimes improved and the Wassermann reaction remained strongly positive, as was anticipated. The clinical improvement was most conspicuous in cases of gummata in the third stage, whether these were ulcerating or still closed; there seems to have been no objective improvement in cases of roseolar or early maculopapular eruption, although improvement was observed in some cases of condylomata, and adenitis was not influenced to any degree. The most interesting observation was that all the cases treated with vaccine responded thereafter in a remarkable manner to injections of salvarsan or its derivatives, whether they had previously been refractory or not. This leads Neuber to hope that the method may be a useful adjuvant to chemotherapy.

JOHN HEYSHAM AND HIS BILLS OF MORTALITY

STIMULATED by Mr. Norman Maclaren, Carlisle has been celebrating the centenary of the death of John Heysham, one of its most distinguished citizens. A special service was held in the cathedral and the Mayor presided at a meeting when Dr. C. W. Graham delivered an oration on Heysham's life and Mr. W. B. Elderton, president of the Institute of Actuaries, spoke of his world-famous tables of mortality.

John Heysham was born at Lancaster on Nov. 22nd, 1753, and went to the village school at Yealand, near Burton, kept by the Quaker brothers Jenkinson. On leaving school he became "doctor's lad" to Mr. Parkinson, surgeon of Burton, and during his apprenticeship pursued the study of birds, which drove him to become expert in the practice of the bow and arrow. His pupilage over he rode on horseback the 170 miles to Edinburgh, where he graduated in June, 1777, with a thesis on hydrophobia (of which he was destined never to see a case in his 50 years' practice). He then sailed from Leith to Rotterdam for a medical tour of Holland, on returning from which he settled in Carlisle, taking lodgings in St. Cuthbert's-lane, where he lived until his death on March 23rd, 1834. Carlisle was at that time beset with itinerant quacks of all descriptions, and Heysham, well equipped though he was with the medical principles of his time, had a struggle to establish himself as the foremost practitioner in the city, and it seems that his annual income never exceeded £400. His commanding appearance, possibly too the conspicuous brightness of his dress, soon served to make him a well-known figure, and his industry was enhanced by excellent health, for he did not have a single day's illness during his life of 82 years, and this in spite of a well-earned reputation as an epicure. Quite early in his career his thoughtfulness for the needs of his poorer patients led him to apply to the Dean and Chapter for a room above the Abbey Gate in which was founded in 1782 the Carlisle Dispensary, which moved later into the Tithebarn, Heads-lane, and in 1857 to its present site in Chapel-street. This record would have secured him affectionate memory among his fellow citizens, but it was a remarkable excursion into medical statistics that gained for him a wider fame. A few months after settling in Carlisle he meditated a census of the inhabitants and the framing of bills of mortality. He first made sure of the number of the population of Carlisle by a method that in point of accuracy almost amounted to a personal registration of each individual family. This exacting work went on until 1787, when his courtship of the daughter of a rich tanner diverted his attention in other directions. His achievement may be stated in Mr. Elderton's careful words: "He counted the houses and inhabitants, tabulated his results, counted the deaths and set out the causes of death, age by age, person by person, recorded influences likely to affect his statistics, and then took a second census similar to the first. . . . In this and similar tedious work," he added, "lie the roots of all discoveries, the proof or disproof of any scientific theory, the test of every social remedy—the measure of all improvement." Heysham's work might have remained unnoticed had it not been for a letter dated Sept. 12th, 1812, written from the Sun Life Assurance office in London by its actuary, Mr. Joshua Milne. "Being engaged," he wrote, "in enquiries relative to Human Mortality, and having met with your valuable Observations thereon that were published at Carlisle in 1797, I have constructed a Table of Mortality from them, whereby it appears that the inhabitants of your city surpass in longevity those of any other place (so far as I am informed) for which a similar table has been constructed." This led to a correspondence between the two men, given at length in an appendix to the "Life of John Heysham," by Dr. Henry Lonsdale (Longmans, 1870). Milne finished his work on the Carlisle statistics in 1815 and his tables were still used for annuity valuations in 1875 and even later. They were adopted by other leading assurance companies as the most trustworthy data, superseding the official system then current, and being accepted both in this country and abroad.

---

[1] Dermat. Woch., Feb. 24th, 1934, p. 229.

It was fitting then that the gathering at Carlisle should have been attended by actuaries and representatives of many life offices. The occasion was utilised to support an appeal fund for renovating the dispensary which Heysham founded. This year too will see the opening of the park in the Raffles area of Carlisle provided by a sum of money left in trust to the city by Heysham himself which has been allowed to accumulate.

A CHEST DIAGNOSTIC SURVEY

AMONGST the various schemes for dealing with the unemployed in New York is one which has a wider significance for civic health than the immediate relief of distress. Dr. John L. Rice, the new health commissioner for the city, records an intensive X ray study of unemployed and their families in the form of a chest diagnostic survey, made possible by a grant from the State Temporary Relief Administration. For this purpose the paper roll film which only costs about one third of the celluloid film has been used. Surveys of the first two sections of the city, Central Harlem and Red Hook, made in 1933 have now been published. A third survey in the West Side section is being undertaken under the direction of Dr. Margaret Barnard who has been closely associated with these X ray studies.[1] Some 20,000 persons have been examined, among whom 512 cases of tuberculosis have been found. Hitherto only 15,727 registered cases were known in the city as a whole. Dr. Rice estimates that if the ratio of cases discovered amongst the unemployed of the Harlem and Red Hook sections prevails in New York City as a whole, the cases should total 180,000. Another surprising fact has been the number of positive cases amongst the white population. In the Harlem district the white women led all others in the proportion of pulmonary tuberculosis. In the Red Hook district, although it is predominently white, the group study showed about 54 per cent. more tuberculosis than in the overwhelmingly coloured Harlem district. These studies suggest that in the unemployed population tuberculosis is four and a quarter times commoner in white than in coloured persons, a surprising and unexpected result. The cases discovered have been placed under treatment.

Use of the paper film has not only lowered the cost of this survey to an economic level, it has enabled the physician to take skiagrams of more than 500 persons a day. Another advantage claimed is the ease and convenience with which the pictures can be read and interpreted, together with an attainment of uniformity in quality. Each picture bears on its face full data regarding the subject—name, address, sex, weight, height—so that time in record making is saved. The diagnosis also may be added to the film, thereby making a complete record of each case. Each 20-ft. roll film contains 100 pictures. The preliminary report issued by Dr. Rice gives no detailed analysis of the X ray findings so that it is not possible at the moment to estimate the value of the paper as against the celluloid film in differentiating between active and inactive, early and obsolete lesions, but the figures are sufficiently impressive to warrant a careful comparison of the two kinds of film in the same patient over a large series.

ILLICIT USE OF NARCOTICS

IN the last report of the advisory committee on the traffic in dangerous drugs to the Council of the League of Nations attention was called to a practice which is becoming prevalent in the Far East of smoking heroin pills. An analysis of these pills made by Prof. E. Knaffl-Lenz, of Vienna, showed that they contain caffeine as well as heroin and sometimes also strychnine or quinine. It appears that at least one-third of the heroin content would pass over to the consumer in the smoke and is capable of producing its physiological effects.

The report of a subcommittee on seizures of illicit drugs contains interesting information regarding contraband traffic in the United States, whence more seizures have been returned than in any other single country. The heaviest arrivals of raw opium were on the Atlantic coast, mostly from Italian ports but of Turkish origin. On the other hand, "prepared" opium reached the States on the Pacific coast by ships from the Far East en route from Hawaii. Illicit morphine entered the States by various routes—e.g., from Japan and China on the Pacific coast, from French ports on the Atlantic sea-board, and from Germany through Central American countries. It is reported that "all the circumstances point to a continuance of illicit traffic in morphine from Western Europe to the United States on much the same scale as for several years past, with a development of new methods of concealment and transportation." Appreciation is expressed at the valuable coöperation of enforcement officers in the United Kingdom, Canada, Egypt, France, Germany, and the Netherlands in tracking and exposing the agencies employed in this illicit commerce. Although the position is certainly better than it was a few years ago yet "it is by no means safe to conclude that illicit import is decreasing."

THE death is reported from South Africa of Dr. Charles Porter, for many years medical officer of health for Johannesburg.

AN election will take place in July next for members of the Council of the Royal College of Surgeons of England. There are four vacancies, and the following Fellows are standing for election :—Ernest William Hey Groves, George Grey Turner, Hugh Lett, C.B.E., Alfred William Sheen, C.B.E., Duncan Campbell Lloyd Fitzwilliams, C.M.G., Gwynne Evan Owen Williams, Ernest Cranmer Hughes, O.B.E., and William Girling Ball. Of these candidates the first three are retiring from the Council in rotation and offer themselves for re-election.

PROGNOSIS

A Series of Signed Articles contributed by invitation

I.—PROGNOSIS IN GALL-BLADDER DISEASE

To the patient suffering from gall-bladder disease, especially that form of it which is associated with recurrent attacks of severe pain, the practical problem of relief depends on the likelihood of improvement or cure under medical measures or the dreaded necessity for operative treatment.

Does inflammatory disease of the gall-bladder ever clear up completely? Does it often pass into long periods of quiescence? If gall-stones have formed may they, under treatment, dissolve or be passed by the bowel? Is the patient's general health likely to suffer from the presence of a diseased gall-bladder, and is any risk to life run by leaving a diseased gall-bladder in situ? Does surgical treatment involve much risk to life? If survived, will the operation relieve all the symptoms? What chance is there of the trouble recurring after operation? Does removal of the gall-bladder per se give rise to any disagreeable or disabling symptoms? Does the presence of a stone or stones in the common bile-duct make the operative risk and the future prospect grave? What is the outlook from operation in the patient who is deeply jaundiced?

These and other questions are being raised daily in practice, and in this communication I will endeavour to answer them.

Might I first emphasise the difficulty in some cases of being sure of the diagnosis and thus of assessing the value of various forms of conservative treatment? I have on more than one occasion, whilst operating for another upper abdominal lesion, exposed a perfectly normal gall-bladder, the known disease in which was said to have been kept in abeyance for years by careful medical treatment. It is inevitable, therefore, that in any series of cases treated on medical lines, we will have a number in which the diagnosis was sufficiently in doubt as to make accurate statistical record impossible. On the other hand, we have a sufficiency of cases in which the diagnosis was clear, and in which medical treatment was employed, to give an approximately accurate estimate of prognosis.

CHANCES OF SUCCESS WITH MEDICAL MEASURES

Have we any reason to doubt that inflammation in the gall-bladder will clear up completely in a certain number of cases? We know that cholecystitis is frequently a chronic and indolent disease; that the causal organism is embedded in the gall-bladder wall and is killed or dislodged with difficulty. We also know that the common association with gall-stones and the intermittent obstruction of the cystic duct which is liable to take place aggravates and perpetuates the cholecystitis. None the less it is true that in a certain number of cases of indubitable cholecystitis, symptoms have disappeared for long periods of years after medical treatment and a lasting symptomatic cure has been effected.

If we have diagnosed the presence of gall-stones, either from typical biliary colic or from X ray demonstration, what chance is there of cure by medical treatment? It may be said at once that no known drug or diet will cause the solution of gall-stones. Can we induce the passage of the stones by way of the ducts and bowel? There is no question that sometimes after the administration of generous doses of olive oil a number of small stones may pass, and this form of treatment is well worth a trial, provided we do not know that there is a stone present the size of which makes passage down the ducts impossible. Experience points to the percentage of cases in which such treatment can be followed by lasting success being extremely small—in the region of 5 per cent.

We have obtained abundant evidence in the past few years of the sinister consequences of untreated gall-bladder infection. Firstly, a stone may lodge in the common bile-duct and give rise to the disabling, and sometimes dangerous, symptoms which follow obstruction of the duct. A suppurative obstructive cholecystitis may be followed by a subphrenic abscess or a pylephlebitis, or a large stone ulcerating through into the intestine may cause acute intestinal obstruction. A pancreatitis, either of the slow sclerosing variety or of the dangerous acute hæmorrhagic type, may develop. Toxic changes in the heart muscle, in the fascial planes, in joints and in kidneys, resulting from absorption of organisms and their toxins from the chronic infective focus in the gall-bladder, are now known to be not infrequent sequelæ of cholecystitis.

Apart then from the dangerous complication where life is in jeopardy, an indolent gall-bladder infection may play a definite and important rôle in bringing about those degenerative changes which, coming on in late middle life, precipitate the patient into a premature old age.

FACTORS DIMINISHING OPERATIVE RISKS

What is the immediate risk attached to operations on the biliary passages? It is obvious that the answer to this question depends on several factors—viz., the care taken in pre-operative preparation, the skill and experience of the surgeon, and the quality of the nursing in the post-operative period. Many patients with biliary disease are bad subjects for operation. They are often very stout and breathless on exertion, and in some cases are poisoned and jaundiced.

The immediate prognosis will be greatly improved if an appropriate pre-operative régime be instituted. If the patient is very obese a delay of three months, during which weight is reduced on a suitable diet with regulated exercise, will facilitate the operative manipulations, and, by ensuring well-maintained cardiac action, will lessen the risk of post-operative thrombosis and embolism. Since adopting a period of pre-operative dieting and physical training in stout, flabby subjects, I have found my mortality-rate in biliary surgery has been reduced to half its previous level. An adequate pre-operative supply of fluid and sugar is another safeguard, especially in cases in which an infected and obstructed common bile-duct has led to loss of weight and impairment of hepatic efficiency.

In uncomplicated cases of gall-bladder disease in which operation has been undertaken on account of recurring colic or chronic dyspepsia, the risk to life from removal of the gall-bladder should not be more than 2 per cent. Evacuation and drainage of the gall-bladder in such cases should bear an even lower mortality; but it is not advised because a diseased organ is left behind, gall-stones recur in approximately 10 per cent. of cases, biliary dyspepsia may persist, and, in some cases, carcinoma of the gall-bladder develops.

Emergency operations.—In cases of acute obstructive cholecystitis where the condition does not yield to expectant and medical measures, operative treatment of an emergency nature must be undertaken. This should consist merely in an exposure, opening and evacuation of the gall-bladder, followed by drainage. In elderly subjects with a tendency to chest complication this operation is by no means free from risk. A preliminary narcotic and local anæsthesia will permit of adequate access and is well tolerated. Where the gall-bladder is partly gangrenous *B. welchii* is usually found. In such cases the abdominal wound should be left open and packed and anti-welchii serum—40 c.cm.—given at once. After such emergency operations recovery may be complete and lasting. My experience has been, however, that in 50 per cent. of such cases symptoms recur, often with the formation of further stones, and in two of my cases with the development of carcinoma of the gall-bladder. Owing to this tendency to persistence of some of the symptoms, to the recurrence of stones, and to the development of malignancy, the operation of drainage of the gall-bladder has been largely superseded by that of removal.

RESULTS AFTER OPERATION

What chance is there of persistence of symptoms after removal of the gall-bladder? We find, from a follow-up, that the patients are relieved of symptoms in over 70 per cent. of cases. The poor results and the qualified benefit are found, for the most part, in the cases in which the pre-operative symptoms were somewhat atypical and the pathology disclosed at operation was not gross. Flatulence, heartburn, and intolerance of fats are the usual residual symptoms. Occasionally attacks of colic will persist after operation, to the chagrin of both patient and surgeon. Such attacks may mean that a stone in the common bile-duct has been overlooked or merely that the sphincter of Oddi is still subject to spasm. Patience and belladonna are indicated for some months after operation in such cases, and only if jaundice supervenes should further operative interference be considered.

There is a fairly widespread impression that after removal of the gall-bladder a patient never quite regains normal digestion. This is quite erroneous. I have questioned many hundreds of patients on this point and the unanimous verdict is that digestion is as good as ever and better than for many months or years before operation. The only exception is where a functioning gall-bladder, the seat of early disease, has been removed; here for some months vague digestive disturbance results but in course of time gradually disappears.

An analysis of the cases in which, following cholecystectomy, troublesome symptoms have persisted has shown that in the majority the disease in the gall-bladder was mild in degree and without stones, and at operation some hesitation existed as to whether extirpation of the gall-bladder was justifiable. In such cases the diagnosis was probably wrong and the operation of cholecystectomy must bear unwarranted discredit. In some cases a stone in the common bile-duct had been overlooked and little, if any, benefit has resulted. In some such cases the disappointed patient will have no further surgical interference; in most, luckily, the patient consents to a second operation, when the duct is cleared, the patient relieved, and surgery rehabilitated.

The lesson is that the common duct should always be displayed and, if any doubt exists, opened and explored at every operation on the biliary tract.

STONE IN THE COMMON BILE-DUCT

When a diagnosis of stone in the common duct is made, surgical treatment should always be recommended. The possibility of a stone, which has been arrested in the duct, passing on into the duodenum becomes less with every day. Surgical treatment, whilst imperative, should not be precipitate. If intermittent jaundice and fever have punctuated the course of the illness, operation should, if possible, be timed to occur with a waning jaundice and a receding infection. When this can be done the risk of operation does not exceed appreciably that of cholecystectomy. If, on the other hand, the obstruction of the duct is complete, jaundice progressive, the stools devoid of bile, and the patient apathetic and drowsy, operation is demanded without undue delay and the prognosis must be guarded.

In the first case chemical disinfection of the ducts by large doses of hexamine and the "schutztherapie" for the liver—glucose and insulin—may with advantage be carried on for a week or more. In the second case intensive pre-operative therapy over a period of 48 hours by intravenous administration of fluid and glucose, of calcium chloride, and of blood, will lessen the considerable risk of hæmorrhage and of hepatic insufficiency, but will not render safe what must be at all times a dangerous procedure.

If on opening the common duct colourless fluid escapes—white bile—this is an index of severe back pressure on the liver and a bad prognostic feature; it calls for special efforts to promote liver function by fluid, glucose, and by diathermy to raise the temperature of the liver.

In spite of all our efforts the death-rate in the deeply jaundiced patient will remain high, not less than 20 per cent. Consequently, we should see to it that patients presenting symptoms of stone in the common duct are not left until they reach a dangerous condition requiring desperate measures.

CARCINOMA OF THE GALL-BLADDER

When malignant disease of the gall-bladder occurs it is almost invariably as a sequel to gall-stones. The gall-bladder is not a very common site for cancer—I have had to deal with 32 cases among some 800 cases of gall-stones, and in just over 1000 operations on the biliary passages. Frequently it does not declare its presence until, on the one hand by obstructing the neck of the gall-bladder, it gives rise to a palpable mucocele or empyema of that organ, or on the other hand by pressure exerted by invaded lymph glands on the common duct it causes jaundice. Seldom, therefore, can the growth be successfully removed—the only successful cases in my experience are those (two cases) where it was discovered accidentally on opening a gall-bladder removed for gall-stones. In all other cases where removal was attempted early recurrence in the liver has taken place. Practical experience of these cases convinces one more and more of the advisability of removing and not simply draining the diseased gall-bladder.

D. P. D. WILKIE, M.D., F.R.C.S.
Professor of Surgery, University of Edinburgh.

AT the recent annual meeting of Melksham Cottage Hospital it was announced that the hospital is about to receive the legacy of £100,000 bequeathed by the late Mrs. Ludlow-Bruges, who formerly lived in the neighbourhood. Owing to the appreciation of securities the sum mentioned will probably be exceeded. A new wing is to be built with a portion of the money. The year 1933 closed with an adverse balance of £639, and the rating assessment of the hospital has been raised from £10 to £87.

SPECIAL ARTICLES

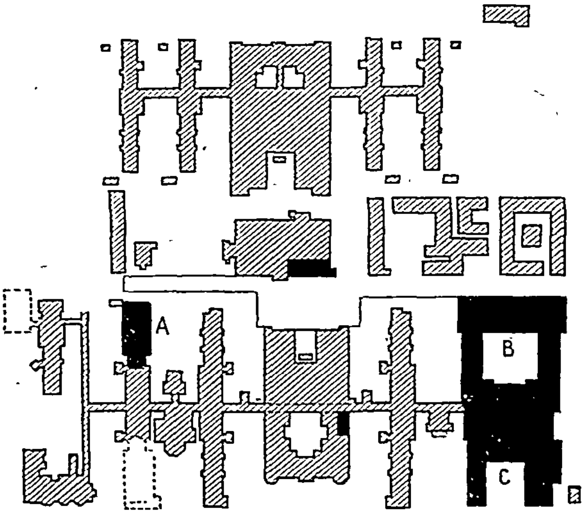
BRITISH POST-GRADUATE MEDICAL SCHOOL

BUILDING is progressing rapidly at Hammersmith Hospital in fulfilment of the scheme which, if all goes well, is to produce by December the framework of a new post-graduate medical school. The foundation-stone was laid last July[1] by Mr. Neville Chamberlain, Chancellor of the Exchequer, in the presence of Sir Austen Chamberlain, chairman of the Governing Body, Lord Athlone, chancellor of the University of London, Sir Hilton Young, Minister of Health, and Mr. E. M. Dence, chairman of the London County Council. The scheme is the joint concern of H.M. Government, the University of London, and the London County Council, and by the courtesy of the Governing Body and the Council we are able to reproduce here the detailed plans of the new buildings.

The foundation of a new medical school in London is in itself an event of some interest. No one living can remember the foundation of any of the 12 undergraduate medical schools in the metropolis. Their growth and development has been dictated by experience of their particular needs, reconciled as far as possible to exigencies of site, finance, and available space. The new post-graduate school is a building de novo, not like the hospital to which it is attached, an adaptation and extension of existing premises; it has been designed and is being carried out solely to embody the ideals of its promoters. What these intentions are may be gathered from the report of the 1930 committee which set out to provide facilities for at least three different classes of students. In the first place, in addition to the permanent teaching staff (professorships in four subjects—medicine, surgery, gynæcology and obstetrics, and pathology—have been advertised), the provision of courses by visiting experts, including acknowledged leaders in medicine and surgery, should, they thought, attract students from the Empire and abroad who at present have no means of taking advantage of practical work in this country. Secondly, they bore in mind the further need for scientific training on the part of those who have qualified at one or other of the British undergraduate medical schools, either in London or elsewhere, with the expression of a hope of bringing these schools into closer interrelation than exists to-day. Thirdly, they were keenly aware of the need of short and highly concentrated refresher courses for practitioners, especially those in the country, to keep them in touch with new developments in medicine and surgery. As one example there are 17,000 practitioners working under the National Health Insurance Acts, and year by year a certain proportion of these should have a chance of taking such courses at a post-graduate school. The plans of the school will be closely scrutinised to see how a committee of great distinction has sought to put these objects into being.

THE CHOICE OF SITE

A domicile for the post-graduate school was a matter which had perplexed and eluded successive committees. The ideal solution of a new hospital specially built and equipped was finally turned down even in times of less financial stress than the present; overtures to one and another of the undergraduate teaching schools, although long entertained, ultimately came to nothing. Four years ago an association with an existing voluntary hospital was becoming definite, when it was seen that the London County Council was itself shortly to be charged with the duty of providing and maintaining public accommodation for the sick poor in London, and the attachment of the school to a public municipal hospital became a new and exciting possibility. The choice gradually narrowed down to hospitals at Lewisham and Hammersmith (Ducane-road), and finally fell on the latter. The choice of site may be regarded as a happy one, for the hospital is finely situated to the south of a large area of open ground known as Wormwood Scrubs, which is assured in perpetuity. On the west lies the famous prison; and the extensive plot on the east will also remain open, for it has been acquired by the governors of St. Clement Danes grammar school. Ducane-road itself ceased to be a main thoroughfare when Western-avenue was pushed through parallel to it 100 yards away. Between them lies the Central London Railway, on which the new London transport board should be willing to make a stopping place near the entrance gate of the hospital, which would then bring it within a quarter of an hour of Oxford Circus. The grounds of the hospital itself cover 14 acres, and provide ample room for further building.



Lay-out of the Hammersmith Hospital, showing existing buildings in grey and additions in black. A is the new hospital wing, with a group of operating theatres. B is the medical school proper. C is the new casualty and out-patient department.

THE EXISTING HOSPITAL

The hospital now contains 400 beds, a modern maternity ward with 16 beds and an antenatal clinic, but is without tuberculosis or venereal departments, or any organised out-patient department except for the following-up of previous in-patients. The buildings were not carried out completely as planned[2] in 1905 by the architects, Messrs. Giles, Gough, and Trollope, when economy already stepped in, but the ward blocks are well built and serviceable with a certain dignity about them. The administrative block, as in so many of the legacies from the poor-law, has a number of the best characteristics of the comfortable private house. Important additions were made when it was taken over during the war, and remained from 1918–24 as an orthopædic hospital of the Ministry of Pensions; an excellent range of workshops was built, and a fine room for remedial exercises which now serves usefully as a common room and lecture room for the nursing staff. At this time was built on a temporary basis, but still functioning heartily, a fine operating theatre to the specification of the late Sir Robert Jones. The long east-west corridor which crosses and links up these buildings conveniently will make it readily possible for every ward in the hospital to be used for teaching purposes, and for a case in any of them to be transferred in bed to the clinical theatre of the new medical school. The old stationary beds are already being replaced by wheeled ones—four wheels perhaps would be better than two, and, before it is too late, the committee might consider the ingenious plan adopted at the Clavadel surgical clinic of putting rubber-tired discs on all four legs about a foot from the ground, and a metal strip at corresponding height along all the corridors that the beds are likely

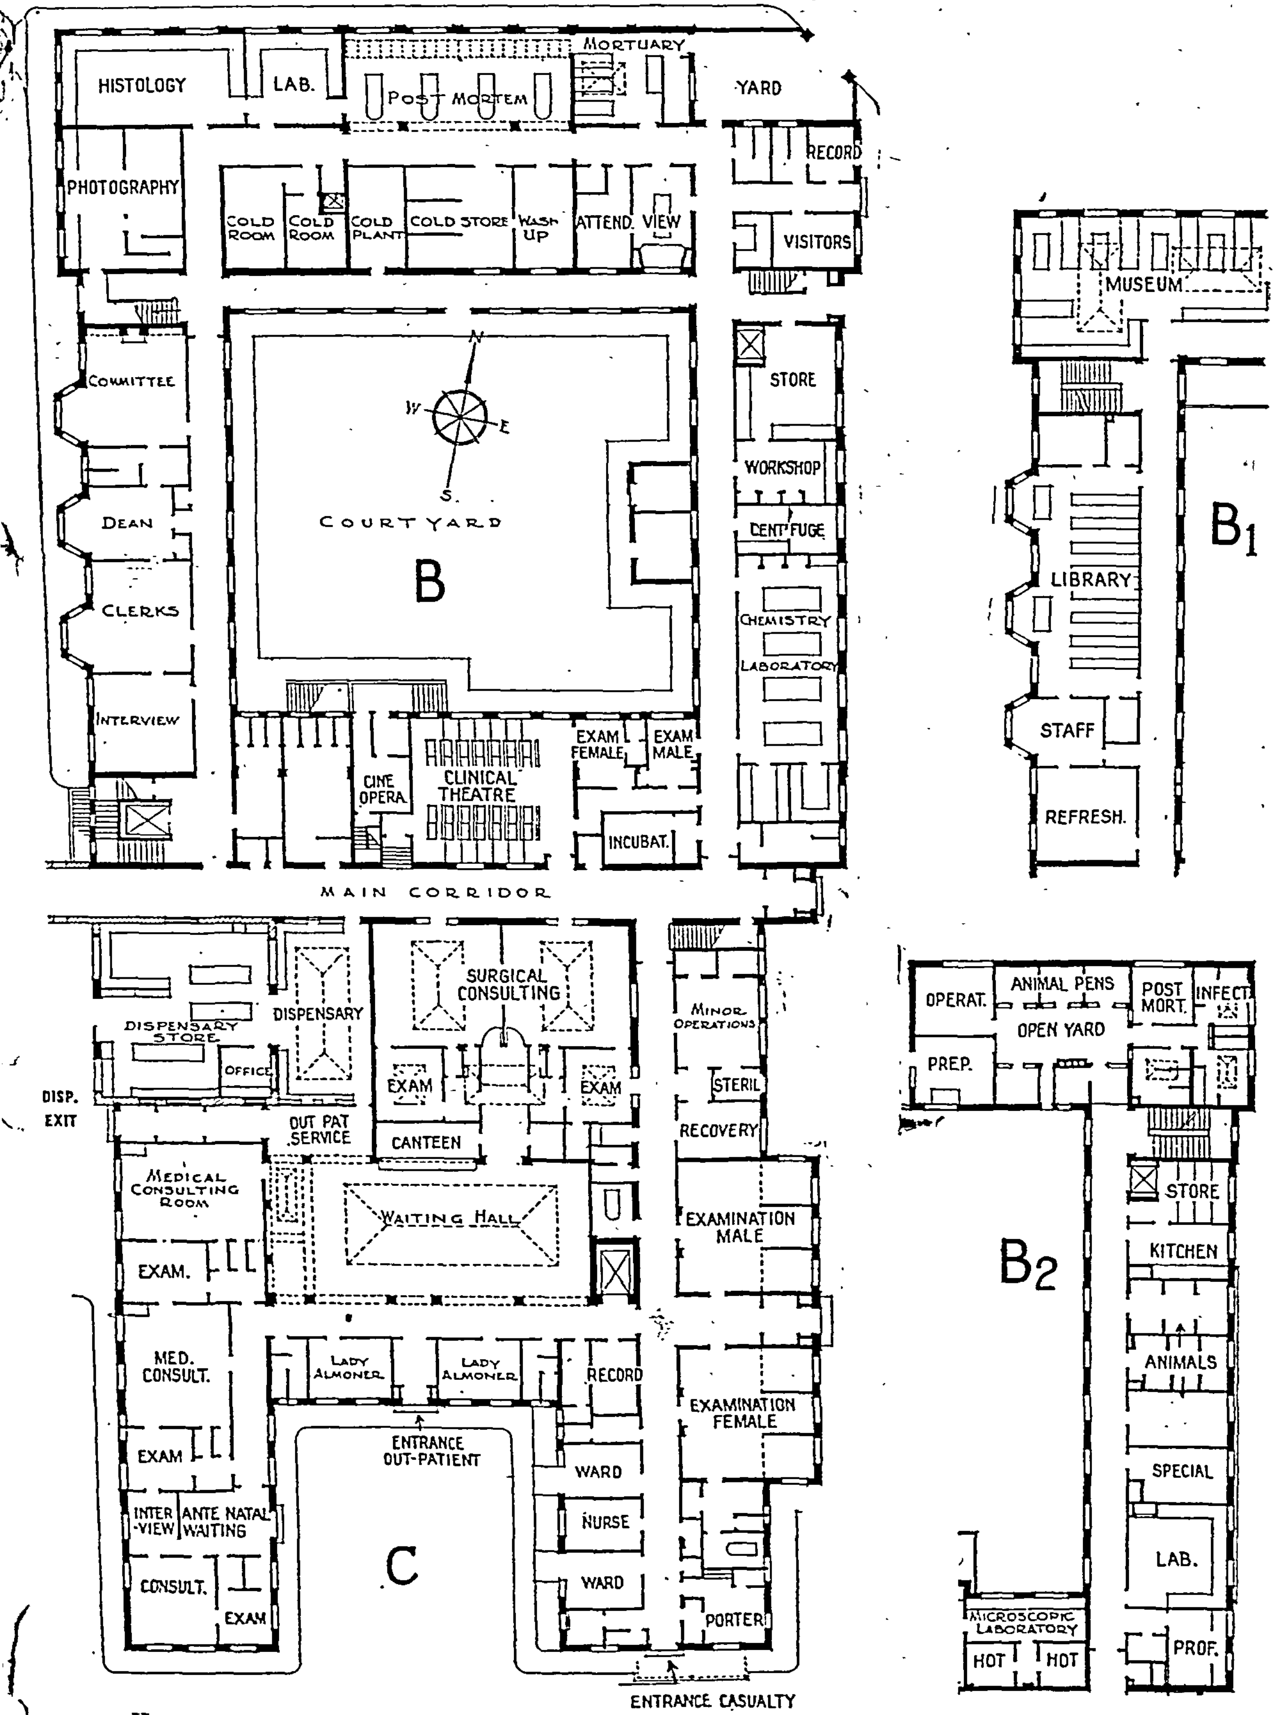
Hammersmith Hospital: plan of the new surgical and maternity block (A).



Hammersmith Hospital: ground-floor plan of the medical school (B) and new out-patient department (C). Parts are also shown of the first floor (B₁) and second floor (B₂) of the medical school.

to traverse—a device which saves the inevitable scratching of the plaster.

At the present time the northern half of the site is occupied by an institution not yet appropriated by the public health department of the L.C.C., and still occupied by infirm aged persons. The central block of this building already serves as quarters for some of the resident staff, and could be further so utilised to almost any extent—incidentally its northern outlook is on a particularly sequestered parcel of ground behind the rifle butts, already used by birds as a sanctuary. It is part of the organisation committee's plan to provide accommodation for a limited number of post-graduate students, some of whom would during their period of residence be holding temporary appointments on the staff of the hospital as internes. When this section is appropriated next year two of the four wings might provide the promised material for the study of chronic disease not usually available at voluntary hospitals; the other two wings would become available for extension of accommodation for nurses, who are unfortunately not in so favourable a position as had been hoped. The original nurses' home can only accommodate about half of the nursing staff at present required, and the personnel is scattered in three different parts of the hospital. The new nurses' home which had already been contemplated by the guardians before the hospital came into the hands of the L.C.C.—to be built for 100 nurses in the first instance, and capable of enlargement so as to house 200 to 250—came under the economy axe, and later was one of the items sacrificed when the Government grant to the new scheme dropped from £250,000 to £100,000, and the expenditure of an equivalent amount contemplated by the L.C.C. was correspondingly reduced.

As will be seen from the lay-out plan, the new building comprises three sections: (A) a surgical ward and maternity section with a dual group of operating theatres designed to complete the equipment of the hospital; (B) the medical school proper; (C) a new casualty and out-patient department with special X ray departments on the first floor, and a skeleton second floor pending ultimate requirements. The minor additions marked on the lay-out are for a new boiler in the engine-house and a central sterilising room in the basement of the central block.

NEW SURGICAL AND MATERNITY BLOCK

This (marked A in the plan) is an extension in four stories of the northern wing of an existing block of the hospital. It abuts directly on the main east-west corridor and has a full-sized lift which will make it possible for a bed to be wheeled from any part of the hospital to any floor of the new block. On the ground floor is a surgical ward of 24 beds, opening freely to a verandah on the west side; it may be hoped that the roof of this verandah is on the cantilever principle, leaving nothing to obstruct the outlook. The beds are arranged on the lengthwise principle now familiar at the new Southend hospital, but differing slightly owing to the width of the building, which made it necessary to place four beds instead of two in each compartment. On this floor there are also three small one-bed wards. The first and second floors are taken up by a well-equipped maternity department, the plan of which is still subject to minor variations. On the first is an observation ward of eight or ten beds, with an emergency delivery room and a number of small ante-natal rooms. On the second are two large delivery rooms, as well as a ward of five beds for the first stage, and other accessory rooms. On the third floor are two identical operating theatres facing due north, each with its own suite of anæsthetising ante-room and a wash-up room for the surgeon and his assistants. The sterilising room, which occupies a central position, is top-lighted. A study of the plan will show to what extent experience has been utilised in the arrangements for system and cleanliness.

THE MEDICAL SCHOOL

This (marked B on the plan) occupies the north wing of the new east block; it consists of three floors around a central courtyard. On the ground floor is the clinical theatre, with seating room for 100 students, directly abutting on the main east-west corridor of the hospital, with a room for a cinema operator on the one side and examination rooms for patients on the other. On the north side of this floor is a very complete pathological department centring around a top-lighted post-mortem room with four tables, attached to which is abundant cold storage. The adjacent mortuary opens on a yard with a separate entrance to the street and completely cut off from the rest of the hospital. Alongside are rooms for histology and photography, and a service lift to take material up to the museum and preparation laboratories on the floor above. On the east side are chemical laboratories with workshops, stores, and centrifuge room; on the west side are the committee room, the offices of the dean and clerical staff. On the first floor, of which only the north-west portion is reproduced here (B_1), are the library and museum, as well as the lecture theatre which lies over and duplicates the clinical theatre below. Here are the laboratories for the professors and a number of other laboratories large and small, with a small refreshment room, an earnest of the restaurant which is one of the desiderata in the next extension, when presumably space will be found for it in the northern administrative block. On the second floor, of which only the north-east portion of the plan is reproduced here (B_2), is a large animal section with preparation, operating, and post-mortem and infectious rooms, abundant pens and cage accommodation. All this is opening on a flat roof and completely shut off from the rest of the building. On this floor also are microscopic and other laboratories, with hot rooms and autoclaves. The completeness of the arrangements for pathology suggest the intention of a full-time chair in this subject, as well as in medicine, surgery, and obstetrics. Pædiatrics and most of the specialties will still have to be studied elsewhere. On the other hand, the arrangements will be elastic enough to provide material for the "ad hoc" teaching on which Lord Dawson has laid stress, and especially for experienced teachers from overseas to take a share in the curriculum. The noteworthy absence of the specifically preventive side of medicine is accounted for by the fact that complete provision is made for post-graduate teaching of this at the London School of Hygiene and Tropical Medicine at Keppel-street.

OUT-PATIENT DEPARTMENT

This (marked C on the plan) is a novel feature for one of the L.C.C. hospitals. In justifying to the ratepayers the outlay of some £100,000 on this and the surgical block the chairman of the central public health committee pointed out how greatly these additions will improve the medical and surgical treatment of the sick of London and enhance the value of the Council's hospital service. The concentration at the school of the best medical and surgical skill available to teach on modern lines will give opportunities to the Council's medical staff of instruction in the most modern methods of treatment; patients from any of the Council's hospitals can be sent to Hammersmith for the purpose of diagnosis and the specialised treatment available there. The hospital is situated in a rapidly growing neighbourhood—East Acton has sprung up almost in a night—and there is no casualty department nearer than the West London Hospital, 1¾ miles away. The department occupies the whole south wing of the east block, and is situated just opposite the main entrance to the hospital. Nearest to the gate is the entrance for casualties adjoining the porter's lodge; here are two small wards separated by the nurses' room, with ready access to all the other facilities of the department. The entrance for out-patients is in the centre of the block, and opens into a top-lighted waiting hall with sitting room for 300 persons, served by a canteen. Opening out of this hall are two rooms for the lady almoners and suites of consulting and examination rooms, including a theatre for minor operations with recovery room. There is a separate antenatal section with its own entrance. A large new dispensary serves both the main hospital and the out-patients, who have their own entrance and exit. The first floor of this block, which is much reduced in size, contains on the one side a large X ray therapy section, and on the other dental rooms, rooms for heart and lung and gastro-intestinal cases, conveniently separated by the dark room, a fracture room, and various other rooms whose use is likely to be determined by experience. The second floor of this block will remain in skeleton pending ultimate requirements.

We may conclude this account of the buildings themselves with a reminder that the agreement between the London County Council and the Governing Body of the School may be considered to be of a permanent character, although the licence granted to the School for occupation of the new premises is restricted to a term of 999 years. The appointment of the professorial and technical staffs is a matter for agreement between the two bodies. The responsibility for the care of patients will continue to rest with the Council, and while the proper duty of the School is teaching the two functions are in practice inseparable, at least with regard to the more senior posts. The School will depend for its main income on a grant from the University Grants Committee administered through London University (which has two representatives on the Governing Body), but will also receive a payment from the Council in respect of services rendered to the hospital, and, in addition, fees will be charged to students attending courses. The agreement between the two bodies further provides for the setting up of a joint committee, on which the School and the hospitals and medical services committee of the Council will be equally represented, in order to determine all matters of joint concern.

COVENTRY AND WARWICKSHIRE HOSPITAL.—The management of this hospital has decided to acquire the adjoining City Fever Hospital, alter, enlarge, and equip it as an extension. An appeal is therefore being issued for £100,000, which would make it possible to pay off the overdraft of £25,000. The existing facilities have become hopelessly inadequate. The out-patients' department can no longer cope with its rapidly growing attendances, and there is a waiting-list of between 150 and 200, and delicate technical treatments are being given in crowded and unsuitable temporary premises. The extension fund at present stands at about £30,000, and the cost of acquiring the City Hospital will be £65,000.

SURPLUS MILK AND SAFE MILK

A POLICY IN OUTLINE

THE steps the Government proposes to take to increase the consumption of milk and improve the supply were described in the House of Commons[1] on Feb. 22nd. Anxiety, however, has been expressed in the medical journals[2] and elsewhere lest the advantage of greater consumption should be bought at the price of safety—especially the safety of children—and it has been emphasised that the support of the profession will be withheld from schemes which do not include satisfactory arrangements for preventing the transmission of bovine infections.

On March 8th a meeting was held at the London School of Hygiene and Tropical Medicine, with Prof. G. S. Wilson in the chair, and a memorandum on the Government's milk policy was drawn up. We publish here a list of the signatories, followed by passages representing the greater part of their statement.

Dr. J. A. ARKWRIGHT, F.R.S., hon. member of bacteriological staff at the Lister Institute of Preventive Medicine; member of the Medical and Agricultural Research Councils.

Mr. J. C. DRUMMOND, D.Sc., professor of biochemistry in the University of London, at University College.

Prof. J. C. G. LEDINGHAM, M.D., F.R.S., director and chief bacteriologist of the Lister Institute.

Mr. F. C. MINETT, D.Sc., director of the research institute at the Royal Veterinary College.

Prof. H. RAISTRICK, F.R.S., professor of biochemistry in the University of London, at the London School of Hygiene and Tropical Medicine.

Dr. G. S. WILSON, professor of bacteriology as applied to hygiene in the University of London, at the London School of Hygiene.

Mr. N. C. WRIGHT, Ph.D., director of the Hannah Dairy Research Institute.

The Memorandum

The desirability of increasing the consumption of liquid milk is admitted on both economic and public health grounds. Investigations on children have shown conclusively the value of a daily ration of milk in promoting physical growth and development. There is reason to believe that the raising of the per caput consumption of milk from its present value of between one-third and two-fifths of a pint to a higher level would be attended by most beneficial results. A propaganda campaign to achieve this object would probably receive the strong support of the medical and veterinary professions, provided satisfactory assurances were given as to the safety of the milk so supplied.

NECESSITY FOR A SAFE MILK-SUPPLY

Evidence is accumulating rapidly that the raw milk-supply of this country is often heavily infected with micro-organisms capable of producing disease in man. An average of 6·7 per cent., running up in some districts to as much as 20 per cent., of samples of raw market milk are infected with virulent bovine tubercle bacilli. Approximately 20–30 per cent. of raw milk samples can be demonstrated to contain *Brucella abortus* which causes both contagious abortion in cattle and undulant fever in man. It is therefore not surprising that in England and Wales about 2000 deaths every year, mainly in children, occur from tuberculosis of bovine origin, and that at least 4000 fresh cases of this disease are notified annually. The occurrence of undulant fever has only been recognised of late years in this country, and its exact incidence is unknown. There are grounds, however, for believing that about 500 cases of active infection with *Brucella abortus*, derived to a considerable extent from milk, occur annually in England and Wales. This estimate, it may be noted, agrees well with the figures of other countries having a similarly infected bovine population.

[1] THE LANCET, March 3rd, p. 491.

[2] THE LANCET, Feb. 24th, p. 405, and March 10th, p. 526; Brit. Med. Jour., Feb. 24th, p. 339.

Besides tuberculosis and undulant fever, numerous milk-borne outbreaks of scarlet fever, septic sore-throat, diphtheria, enteric fever, dysentery, and gastro-enteritis have occurred of late years. We may mention, in particular, two recent outbreaks, one of septic sore-throat at Hove resulting in over 1200 primary cases with 65 deaths, due incidentally to consumption of raw milk coming from an exceptionally well-managed farm, and one of paratyphoid fever at Epping involving 312 persons with 8 deaths.

It is impossible scientifically to escape the implication of these facts—namely, that no raw milk can be guaranteed as safe for human consumption. Milk from tuberculin-tested herds is for all practical purposes free from the risk of conveying tuberculosis, but, as experience both in this country and the United States has shown, it is capable of carrying other infections.

Milk is so liable to contamination, not only from the cow, but also from infected water-supplies used for cleaning utensils, and from human carriers and early cases of disease during its production and distribution, that it must always be considered as potentially dangerous in the raw state.

We do not wish to convey an exaggerated impression of the frequency of milk-borne disease, but we do wish to point out that the potential dangers of raw milk are such as to preclude members of the medical profession who are acquainted with the facts, and who are responsible for the health of those under their care, from recommending it for human consumption.

The logical conclusion to which this argument leads is that all liquid milk should be submitted to some form of adequate heat treatment, preferably low-temperature pasteurisation. There is no doubt that pasteurisation carried out under commercial conditions in properly designed plant efficiently operated can be relied upon to render milk safe. We are of opinion that ordinary raw milk should be pasteurised under official control, and that every step should be taken to ensure that pasteurisation is efficiently performed.

There is reason to believe that if the present Milk Designations Order was amended so as to permit of the pasteurisation of milk from tuberculin-tested herds it would meet with strong support from the medical profession. Hitherto very little progress has been made in the establishment of these herds, partly because the medical profession has no confidence in the safety of Certified and Grade A (T.T.) milk, so far as the risk of conveying diseases other than tuberculosis is concerned. If permissive powers were given to pasteurise milk from tuberculin-tested herds, there would become available a clean safe milk, which we venture to believe would receive very strong support from the medical profession. Experience in the United States may be called upon to justify the truth of this prediction.

The evidence at present available affords no support to the statement still frequently made that pasteurisation seriously diminishes the nutritive value of the milk. The expression of opinion in the Report of the Medical Research Council for the year 1932–1933 amply bears out this conclusion.

There are strong grounds for believing that the adequate pasteurisation of all liquid milk intended for human consumption in this country would abolish the yearly toll of disease and death due to milk-borne infection, and we can see no reason why steps should not be taken to hasten the achievement of this highly desirable result.

OUTLINE OF A MILK POLICY BASED ON SCIENTIFIC PRINCIPLES

The purpose of this memorandum is to offer constructive criticism, and we therefore submit the following proposals outlining a policy which might obtain the support of medical, veterinary, and agricultural interests.

(1) *Stimulation of clean milk production.*—Experience has shown that the production of milk free from dirt and excessive numbers of micro-organisms is possible if a few essentials are adhered to, such as washing of the milker's hands, washing of the cow's udder, and, most important of all, sterilisation of milking utensils. The carrying out of these measures is largely provided for in the Milk and Dairies Order, 1926, and enforcement of this Order would necessarily result in a considerable improvement in the cleanliness of the milk-supply. We would emphasise that dirty milk cannot be made clean by pasteurisation, and that only with milk produced under cleanly conditions is it possible to obtain a satisfactory pasteurised product.

(2) *Permissive powers of compulsory pasteurisation* should be given to towns of 10,000 inhabitants and over. The adequate supervision of pasteurising plants by the local authority should be made obligatory, so as to justify the confidence that the public places in pasteurised milk. Consideration should be given to the possible use of small pasteurising plants by producers in rural districts. All raw milk that cannot be adequately pasteurised should be boiled for use.

(3) *Establishment of a pre-pasteurisation standard of cleanliness.*—It is often urged that pasteurisation diminishes the incentive to produce clean milk. This, we maintain, is unjustifiable. A clean milk is almost as desirable as a safe milk, and the aim for which we must all work is a milk produced under cleanly conditions from healthy animals rendered safe by pasteurisation and distributed in sterilised bottles. A pre-pasteurisation standard of cleanliness, to which all milks intended for pasteurisation must conform, would stimulate enormously the production of clean milk. Such a standard, we believe, is quite possible to set up, and provided it is interpreted liberally in the early stages of its operation, no undue hardship should result.

(4) *Alteration and simplification of the present grading system, with permissive powers of pasteurisation of milk from tuberculin-tested herds.*—We do not propose to suggest new designations at the moment, since they will need a considerable amount of discussion. We do wish, however, to suggest that permissive powers of pasteurisation of milk from tuberculin-tested herds will stimulate enormously the establishment of this type of herd, and will aid the veterinary profession in its campaign against bovine tuberculosis. Pasteurised tuberculin-tested milk will be the cleanest and safest milk on the market; its retail price should not be more than 2*d.* a quart dearer than ordinary pasteurised milk; and it is likely to receive strong recommendation from the medical profession

(5) While in thorough agreement with the desire of the Government to clean up the milking herds of

the country, we feel that nothing short of the *establishment of tuberculin-tested herds* on lines similar in principle to those that have proved so successful in the United States of America is worth serious contemplation. Though clinical inspection and bacteriological sampling of the milk may eliminate a certain number of animals with obvious disease, they can have little ultimate effect on the extent of infection, since animals with clinically detectable disease constitute only a fraction of the total number infected with the tubercle bacillus. They do not accomplish the eradication of tuberculosis, nor do they provide a sufficient guarantee of safety for the milk-supply to justify its increased consumption. We therefore favour a plan, based at first on voluntary coöperation, for the gradual establishment of tuberculin-tested herds, and for the paying of a premium on the milk from such herds whether intended for pasteurisation or not.

(6) We urge that the £750,000 promised for improving the purity of the milk-supply, and of the £500,000 for propaganda purposes, should be devoted to furthering the suggestions laid down in this memorandum rather than on the proposals at present contemplated by the Government.

(7) We further urge that before any definite legislation is introduced, a committee should be appointed consisting of representatives of the producing and distributing interests, and of the Ministries of Health and Agriculture, together with independent scientific authorities, to draw up a plan for the immediate improvement in the cleanliness and safety of the milk-supply of Great Britain. We believe that very striking results might be achieved in a short time at comparatively slight cost if only agreement on fundamental principles was reached. The provision of a clean safe milk-supply is possible only if medical, veterinary, and agricultural interests are united in the support of a plan based on scientific knowledge. The time seems to us to be ripe for the translation of scientific knowledge into current practice.

A Deputation to the Ministers

On March 27th Sir Hilton Young (Minister of Health) and Mr. Walter Elliot, M.B. (Minister of Agriculture), received a deputation introduced by Sir Austen Chamberlain as chairman of the governing body of the London School of Hygiene. The members were Prof. Wilson, Dr. Arkwright, Prof. Ledingham, Dr. Minett, Prof. Raistrick, and Dr. Wright, and their object was to urge the valency of the views set out in their memorandum. In reply the Ministers stated that the points raised were under examination by the Cattle Diseases Committee of the Economic Advisory Council, and the report of the committee and the views of the deputation would receive the careful consideration of the Government. The legislation about to be introduced would be in general terms, and would permit full consideration to be given at a later stage to the matters under discussion.

HOSPITAL COSTS.—Last year the average total cost of each of 2309 in-patients at Worcester Infirmary was £7 10*s.*, as compared with £6 10*s.* in 1932. The average cost per occupied bed was £136 9*s.* 9*d.*, as against £129 18*s.* 10*d.* in the previous year. Each out-patient cost 10*s.* 5¾*d.*, a fractional fall.—At the Chelmsford and Essex Hospital last year in-patients (1877) cost £3 5*s.* 7½*d.* each per week, an increase of 9*s.* 6*d.* per patient; the explanation of the rise was that there were 132 fewer in-patients.—At Croydon General Hospital 2576 in-patients (daily average 116; average stay 16·5 days) cost £6 16*s.* 7*d.* on the average.

HOOKWORM ANÆMIA: ACUTE AND CHRONIC

ACUTE ankylostomiasis is an entity which has been too little studied, and it is useful to have the observations now reported by B. K. Ashford and G. C. and F. K. Payne.[1] The outbreak they describe was in Porto Rico and concerned seven previously healthy persons, of whom six bathed in the sea at a spot where a muddy infective stream was discharging flood water. The whole of those parts of their bodies under their bathing suits became covered with intensely irritating "bites," and acute illness set in with fever, rawness of the throat making swallowing difficult, epigastric pain and vomiting, diarrhœa, intestinal hæmorrhage, and rapidly developing asthenia and pallor. In the most serious case typhoid with hæmorrhage but with delayed agglutination had been diagnosed, but Colonel Ashford was satisfied that he was faced by acute ankylostomiasis, a diagnosis justified by the first appearance of the eggs in the fæces a few days later. Noteworthy is the presence of fever which, it appears, has also been demonstrated as a feature to be expected in acute Mansonian schistosomiasis in Porto Rico. In every case blood, patent or occult, was found in the fæces, and in the most serious of them the loss was so great that the patient's life was only saved by two blood transfusions. The throat symptoms were evidently due to the presence of larvæ there during their well-known passage from skin to intestine. On the digestive symptoms light has been thrown by J. Stewart,[2] whose experience is that heavy nematode infections lessen protein digestion, while from the worms themselves can be extracted a body (he terms it nezyme) which in-vitro experiments show to inhibit the action of pepsin; the effects on intestinal digestion will doubtless be investigated later.

These cases, as well as that of a seventh child who had not bathed but had delved with her hands in the mud bordering the infected stream, were followed by Ashford through daily, and later less frequent, blood examinations for a year; and by the Paynes through examinations of all stools for a month and afterwards on all occasions of anthelmintic treatment, these examinations being so minute as to recover young worms only 1·8 mm. long. Although all but the child bathed for about the same period and appeared to have been about equally peppered with "bites," it is significant that the number of worms recovered varied from 21 to 1439, and from the delving child 7 only. The blood changes were remarkable: a leucocytosis, preponderatingly eosinophilic, reaching its maximum three to four months after infection, the eosinophils in the last case comprising 90 per cent. of all leucocytes. The explanation offered for this striking condition is that it was due to strayed larvæ surviving in numbers in the tissues for that period and then mostly dying, an explanation which though merely inferential at present will have to be in the mental foreground in future work. At all events the fact that such close and skilled fæcal examinations disclosed only 7 worms in one whose hæmoglobin fell to 60 per cent. and erythrocytes to 3,824,000 should give pause to those who hold that 25 intestinal hookworms constitute a negligible load.

As to the cause of the anæmia, the presence and influence of blood loss were unquestionable in these acute cases. But that it wholly explains that of chronic hookworm infection is questioned by C. D.

de Langen.[3] He points out that fæcal blood cannot always be demonstrated, though in general the reaction is such as would have been produced by taking 2 to 3 c.cm. of blood by mouth; and again that the abstraction of one thirty-fifth of a sheep's blood weekly for four years left it in prime condition with a normal blood picture. Nor is increased hæmolysis a sufficient cause, for his experience in this condition is one of lessened fragility of red corpuscles and therefore lessened hæmolysis. The root cause lies in aplasia, and in its production de Langen urges the effects of diet, and in particular implicates the lipoids, cholesterin and the phosphatid lecithin; essentially he uses Miyagawa's theory of autoregulation—namely, that the intravascular death of an erythrocyte provides to the bone-marrow the most important stimulus for the formation of a new one.

The young erythrocyte contains cholesterin which prevents hæmolysis, but as it circulates in the blood it slowly adsorbs lecithin and this, or the higher unsaturated linolenic acid, brings about hæmolysis. There is normally a balance between the two substances, but when adsorption of lecithin reaches a certain level the corpuscle disrupts, and bodies so set free activate the marrow. Thus on a lecithin-rich diet of oats the serum of rabbits may be pink from hæmolysis but the numbers of red corpuscles do not fall; and in a bled rabbit erythrocytes increase, with reticulocytosis, more rapidly on a lecithin-rich diet than in one poor in that substance. This implies that within limits the hæmolysis of erythrocytes within the circulation is the best stimulus to the red marrow to produce more, though, as experiments show, this spurring may be overdone. Moreover in a heavy hookworm infection a considerable area of intestinal epithelium is sucked off, and it appears that it is absorption of lipoids which is first affected by this change.

It is on this basis that de Langen explains the effects of diet in producing hookworm anæmia in Java. It is rife amongst the poorest whose food is frugal with preponderance of carbohydrates, little protein and that vegetable, and fats and lipoids mainly vegetable and of subordinate value. Hæmolysis is thereby lessened, and a daily small loss of blood which would readily be made good by a well-nourished bone-marrow becomes the proverbial last straw. It is, however, noteworthy that, although in malaria hæmolysis occurs within the circulation, in hookworm infection (as has been mentioned) there is less intravascular destruction of red corpuscles than normal, so that their disruption can hardly act directly as a marrow stimulant; nor indeed is their iron stored within the body for the building of new ones. Ashford, too, is sure that in Porto Rico diet is important—that, speaking generally, a diet deficient in protein (in preventive advice he specially mentions animal protein) is a main factor in causing hookworm anæmia, in checking the marrow in its efforts to make good the loss of erythrocytes caused by blood sucking. Dietary defect does not, however, apply to the acute cases he reported which occurred among cultured whites; yet these persons were all still anæmic a year after infection in spite of their economic advantages. But it needs note that none of them had been completely freed from infection even after three to eight treatments with hexylresorcinol and carbon tetrachloride. That such slight infection cannot be disregarded as causing persistence of anæmia the recent report from Syria shows.[4]

In the marrow itself the plastic reaction has its various stages,[5] and at one or more of them the overtaxed marrow evidently ceased to function in the Porto Rican cases. This key position held by the marrow in combating hookworm anæmia has of course long been known; an importance of these investigations is that they throw some further light on the steps of the essential mechanism. This small epidemic is also noteworthy in that infection took place in the sea. It has been known since the opening of the century that the newly hatched hookworm larva is rapidly killed in a salt solution of sea-water strength, so that from fæces deposited in the sea the infection can hardly be carried; but less stress has probably been laid on the observation, known for nearly as long, that infective larvæ have survived in such a solution for a month, so that, as now unhappily demonstrated, a most severe infection can be acquired in the sea when infective larvæ are washed into it and have some such purchase for penetration of the skin as is afforded by a bathing suit.

Ashford's minute investigations were carried out in the face of crippling disability, and the equally exact ones of the Paynes were done with stools often disgustingly offensive from putrefying blood. But their devoted labours have outlined a clinical entity, and their stimulating suggestion as to the effects of strayed larvæ is one which is sure to be further tested. Moreover, their and de Langen's work must weigh heavily against the curiously persistent legend that the gravity of an individual hookworm infection depends solely on the intestinal load, with the victim's body as a passive nonentity.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Lts. (D) to be Surg. Lt.-Comdrs. (D): P. S. Turner, T. G. à C. Emberson, and A. A. Gardner.

The following appointments are notified: Surg. Comdr. W. Gemmell to *Pembroke* for R.N.B.

Surg. Lt.-Comdrs. W. A. Hopkins to *Orion*; S. G. Weldon to *St. Angelo*, and as Naval Health Officer, temp.; and D. A. Newberry to *President* for three months' course.

Surg. Lt. W. D. Gunn to *Victory* and to *London* on recommg.

Surg. Comdr. C. G. Sprague to *Cyclops*.

ROYAL ARMY MEDICAL CORPS

Rex St. John Lyburn to be Lt.

ARMY RESERVE OF OFFICERS

The undermentioned having attained the age limit of liability to recall, ceases to belong to the Res. of Off.: Major P. S. Stewart.

TERRITORIAL ARMY

P. R. Goodfellow (late Cadet Corpl., Clifton Coll. Contgt., Jun. Div., O.T.C.) to be Lt.

INDIAN MEDICAL SERVICE

Majs. N. D. Puri and J. B. Vaidya to be Lt.-Cols.

Capt. E. V. Claydon retires, receiving a gratuity.

Lt.-Col. N. M. Wilson to be Col.

Pritam Varialsingh Karamchandani to be Capt. (on prob.).

ROYAL AIR FORCE

Dental Branch.—Flight Lt. A. P. Atkins is transferred to the Reserve, class D (i).

PANEL AND CONTRACT PRACTICE

The Increase of Canvassing

THERE seems little doubt that the practice of canvassing for patients is on the increase, although it might be hard to ascertain how much of it is due to the difficulty felt by many practitioners to make ends meet, and how much to the lack of ethical training in the curriculum. The General Medical Council has laid down that canvassing is contrary to the public interest and complaints are considered by the Council in this light when brought to their notice. Reference to the index to the Council's minutes will give some idea of its prevalence. It is, however, open to any practitioner who has what he considers sufficient evidence of this practice to lay a complaint before his panel committee. The ethical subcommittee will consider the complaint, and invite the complainant and the doctor against whom he makes the complaint to appear before them to give evidence, upon which they will arrive at a conclusion as to whether the complaint is substantiated or not.

The course to follow in the event of the complaint being substantiated was the subject of debate in the London panel committee at its last meeting. The complaint of canvassing made by Dr. A against Dr. B was found to be proved. It was decided eventually to make representations to the Minister of Health that Dr. B's conduct had been prejudicial to the Service and that he should be removed from the panel. This decision means that the whole case will be tried again de novo by officials of the Ministry when the panel committee will be required to prove that Dr. B did canvass the patients of Dr. A, and both sides are entitled to legal assistance. The case is therefore sub judice, but the facts submitted to the committee may be briefly set out. The practice of Dr. A was originally in the possession of Dr. B. He sold this practice to another practitioner, Dr. C, in October, 1931. Part of the purchase price was paid in cash and a substantial balance was payable by quarterly instalments. Owing to Dr. C borrowing the whole or the bulk of the purchase price, Dr. B has stated that he was not permitted to have any security on the practice. Dr. C defaulted and went bankrupt. The lease of the house which belongs to Dr. B was disclaimed by Dr. C's trustee in bankruptcy, and when the mortgagees sold the practice to a further practitioner Dr. D, the house next door was taken at a lower rent and the practice transferred there. Dr. D in due course sold the practice to Dr. A. This was in September, 1933. On May 9th, 1933, Dr. B returned to his original address to practice, as the usual clause with regard to the restriction of practice was no longer enforceable through the default of Dr. C. Dr. A contended that Dr. B canvassed insured persons on his list to transfer to him. He supported his contention by signed statements from six insured persons. The hearing of this case occupied the committee three days.

This is the first occasion in London that the panel committee has made such representation. There was one previous case of a serious complaint which was tried before the whole committee, counsel being present for both sides conducting the case. But a court of 80 members is too cumbersome, and such cases are now dealt with by the ethical subcommittee. The question naturally arises as to whether it is good policy for the panel committee to act the policeman and conduct a complaint before the Ministry against a practitioner. An amendment was moved that the case should be sent to the medical service subcommittee for investigation, but this was lost by a small majority. The panel committee has no power to call witnesses, and its only penalties are (1) a letter of censure which may be mild or severe; (2) representation to the Ministry for removal from the panel; (3) to send the case to the General Medical Council. The opinion of the minority was that the medical service subcommittee being a statutory judicial body competent to call witnesses and pay their expenses would be better able to present a case to the Ministry than would the panel committee, which would certainly require to employ and pay for legal assistance. The majority however—amongst whom were several who had spent much time on the case in subcommittee—thought the panel committee should have the courage of their convictions, and should not put on other shoulders work they had the power to do themselves.

An Ethical Committee in Search of Truth

The ethical subcommittee of an important panel committee recently had under consideration a complaint made by one practitioner (Dr. A) against another (Dr. B) alleging that he influenced an insured person formerly on his (Dr. A's) list to transfer to him. Dr. A submitted a signed statement from the insured person in question (Miss V) to the following effect:

> "In the summer of 1932 I went round to Dr. B's surgery for medical attention for a friend of mine. Among other questions Dr. B asked me who my doctor was. I told him that Dr. A was my doctor. He then asked me whether I liked Dr. A or not. I told him that I liked him as a doctor. He then asked me if I would like to come on his register. I did not really wish to go on his register so I said I would think it over. I went round several times for medicine for my friend, and he asked me again if I had thought it over. My friend told me he was treating her quite well so I let him have the panel cards of my father and myself. Neither of us signed any letter expressing any desire to change our panel doctors."

Dr. B denied the allegation and submitted a signed statement from Miss V stating that he did not influence her in any way to transfer to him. Both practitioners attended before the ethical committee to submit their observations. Miss V also attended with her mother, apparently at the request of both Drs. A and B. On cross-examination Miss V stated that the statement submitted by Dr. A and signed by herself was quite untrue, and she had done Dr. B an injustice. The report continues: As far as could be gathered from a person of Miss V's temperament, a highly neurotic type, what had transpired was as follows:

> Miss V was originally on Dr. A's list until the end of 1932. She accompanied a friend who was staying at her home to Dr. B's surgery. This friend, who was highly satisfied with the treatment which she was receiving from Dr. B, eventually persuaded Miss V and other members of her family to transfer to Dr. B's list. Miss V, to use her own words, "turned huffy with Dr. B about a whitlow on my thumb," and went to Dr. A in January last with a view to transferring back to him. She states that the statement which she then signed, and which has been quoted in the foregoing, was written by Dr. A, and read over to her by him. He then asked her to read it, which she did, but contends that she did not really understand its purport. She signed the statement because she was sorry for Dr. A, who had told her that his practice was declining. She was averse to signing it, but Dr. A had pressed her to do so. She gave way because she thought she would be doing him a good turn, and that the matter would not go beyond Dr. A seeing Dr. B.

Having considered Miss V's evidence and the observations of the two practitioners, the committee decided to take no further action.

CORRESPONDENCE

THE CAUSAL FALLACY

To the Editor of THE LANCET

SIR,—It is not easy to be sure whether Dr. Graham Howe merely wishes us to have some exercise in the field of philosophy, or whether he is seeking to help us in our daily work by giving us more easily used concepts than those by which, as he fears, we are now being hampered. If it is only the former it is, of course, great fun; but if, as I suspect, he has intended to show us a path, then I regret to say that I find him an obscure teacher, and I should be glad if he could clarify many passages in his discourse.

At one place, for example, he describes time as an aspect of matter, but before that he had been insisting that it was a fourth dimension of space, which looks as if time was an aspect of space. If time is also an aspect of matter is space one, too? All this seems very confusing. When he is talking about the space-time continuum Dr. Howe seems to imply that doctors have neglected the time factor in their work.

"... the time concept has not yet displaced the causal concept in medical orthodoxy. Whether it be in mind or body, the material of our observation is thus four dimensional and time must be recognised as being quite as important as the three geometrical dimensions in space,"

which is, I think, what every doctor does recognise, though not in such grandiloquent language.

I wonder too whether the notion of the space-time continuum is really helpful outside of mathematical physics; whether indeed in non-mathematical thinking it has any meaning at all; whether the constant repetition of the phrase to which we have all been subjected for some years has not induced in us a feeling that it has meaning, when really it has none when used in word language as opposed to mathematical language; whether it is not one of those pseudo ideas which Herbert Spencer warned us against 50 years ago. We are all familiar with the people who think they are expressing an idea when they talk of inferiority complex, and who are dumb if you ask them what they mean by complex. Further, the idea has little relevance to the subject of Dr. Howe's paper, which, so far as I can follow it, has reference to the contrast between thinking of the cause of a thing on the one hand, and the conditions in which things occur on the other. Let us take another example.

"... the causal concept allowed us to understand nothing whatever about force, and in fact has utterly obscured the whole problem so as to make it practically non-existent."

How a concept which failed to make us understand a problem could annihilate that problem I cannot conceive. Apart from this difficulty, is the first part of the statement true? Surely the concept of force arose from certain effects which suggested the need of a cause. The idea of force would never have arisen at all save for the causal concept. Again:

"... the satisfaction of the physician at his patient's recovery may well feel inclined to assume the generous reward of having been the cause through the skill of his remedies."

Probably these last two quotations are merely careless writing and Dr. Howe could probably say easily enough what he does mean; but philosophy is hard enough to understand when it is written about clearly and carefully, and careless framing of sentences in so important a paper is blameworthy. The sentences chosen by no means exhaust the list of the avoidable obscurities in the article.

But, apart from all this, is the concept of causation really so very damaging as Dr. Howe makes out? He suggests that physicians are constantly seeking first causes. I am sure that they are doing nothing of the kind. They are constantly and properly seeking causes, not a cause, which are sufficient for their *purpose*. Every physician is enough of a philosopher to be well aware that the first cause is unknowable, *that the idea of causation* is extremely difficult to understand, but that there are important things the alteration of which will help his patient to get better. Thus he is called to see someone with fever, abdominal pain, rigidity, and a history of vomiting. He opens the abdomen, finds an inflamed appendix, says very properly that this was the cause of the symptoms and knows that its removal will be followed by their relief. It is the merest pedantry to quarrel with him for thinking he has dealt with the essential cause, a thing he most certainly has done; it is of no help to him to think of the matter in terms of endless chains of sequences one of which included a microbe and the other an appendix; and it is certainly not new thought to consider that there had been an alteration of balance between the resistance of the host and the virulence of the microbe. That was old history when I was a medical student.

So much, however, when it comes down to brass tacks, is Dr. Howe dependent on the theory of causation that when he is attacking Sir Maurice Craig on the subject of insomnia he says: "Insomnia, on the other hand, is said to be *caused* (my italics) by pain or worry, or mental restlessness, with or without the existence of some real external agent; of any of these it may be an *effect*, and it is the *antecedent cause*, whatever that may be, which then requires treatment."

Yet elsewhere we are told that "cause is but a phantasy." I am, Sir, yours faithfully,

T. A. ROSS.

Cassel Hospital for Functional Nervous Disorders,
Swaylands, Kent, March 29th.

To the Editor of THE LANCET

SIR,—I am comforted in noting that Dr. Graham Howe, though superior to "causes" in his pathology, is not above "effecting" a restoration of balance by treatment. Effects, in Dr. Howe's hands, have good old-fashioned causes covered with a modern coat of paint in the words "dynamic balance." Hypotheses built cautiously from experience surely must not be damned simply because "causally" tainted. Need we be so careful of our metaphysics? I continue, in spite of the mathematicians (and in their company) to be borne along, a 3-dimensional earthly animal, down an obstinately "one-way" time alley, and the compulsion of flesh and blood seems to me (and to them in their more carnal moments) to be a continual stream of causes and effects. I venture to outrage Dr. Howe's feelings by suggesting that the characters of the universe, even in its present highly delectable and 4-dimensional state, are a "brain-wave," and consequently a *remote and curious effect* of certain mammalian prehensile and phonetic developments.

A hundred years ago Schopenhauer wrote:—

"Philosophers . . . gaily philosophised up in the air until at last Hegelian sophistry (Afterweisheit) reached the happy elevation of denying any parentage to our concepts, and asserting that these concepts are the foundation of all reality."

I wish I knew what Dr. Howe means by "mind-body balance."—I am, Sir, yours faithfully,

Oxford March 28th. H. A. ROBERTSON, M.R.C.P.

MONOCYTOSIS AND GRANULOPENIA

To the Editor of THE LANCET

SIR,—I was interested to read Dr. Hartfall's description of a case of monocytosis and granulopenia with an infection of the gums by Vincent's organisms. In the January issue of the *Archives of Internal Medicine* Forkner describes six cases of acute monocytic leukæmia, with the monocytes in the region of 100,000 per c.mm., and the granulocytes almost down to vanishing point. Four out of these six cases had a Vincent's infection of the gums and pharynx. This certainly looks more than coincidence. Forkner does not appear to have attached any importance to the neutropenia; none of the cases was given nucleotide, and they all died.

I am, Sir, yours faithfully,
Hoveden-road, N.W., March 27th. E. HINDEN.

To the Editor of THE LANCET

SIR,—My enjoyment in reading Dr. Hartfall's paper (THE LANCET, March 24th, p. 620) was a little discounted by my introduction to the term "agranulopenia." Hæmatological nomenclature is already much encumbered by redundant terms and nowhere is this more evident than in conditions in which the granular leucocytes of the circulating blood are diminished. In 1922 Werner Schultz described a condition which he called "angina agranulocytica"; Friedemann, recognising that angina was not constantly present in this syndrome, suggested "agranulocytosis." Since that time the following synonyms have appeared: granulocytopenia, granulopenia (Harkins); malignant neutropenia (Schilling); the neutropenic state (Doan); agranulæmia (Brookes); and granulophthisis (Lescher and Hubble).

This confusion is increased by the fact that, prior to 1922, Schilling had used the term "agranulocyte" to describe an immature cell of the granular class in which granules had not yet appeared. Agranulocytosis is thus an ambivalent word meaning, alternatively, an increase of agranulocytes or a decrease of granulocytes. Dr. Hartfall appears to use his term "agranulopenia" as interchangeable with granulopenia. Etymologically it can, surely, only mean a decrease in agranulocytes, unless the double negative—the prefix a- and the suffix -penia—gives the word, by an unwarrantable pleonasmus, the meaning of an increase in granulocytes.

I feel, Sir, that you will agree with me that our knowledge of leucopenic states is unnecessarily obscured by what you, a few years ago, so happily termed, "Hypernomenclaturosis."

I am, Sir, yours faithfully,
Bournemouth, March 27th. RONALD BODLEY SCOTT.

MEDICINE AND THE RIGHT OF SANCTUARY

To the Editor of THE LANCET

SIR,—The letter from Mr. Somerville Hastings last week (p. 709) raises an exceedingly important question, that of the right of sanctuary of the wounded with a doctor in times of civil war. It is a subject worthy of the serious study of the historian with a sense of humanitarian and legal values. The material for such a study must be vast, and it would be necessary to make it not only country by country, but also century by century. Even if it were to be confined to one country and one century, the historian would find enough material to hand for an engrossing survey. In France, with its glowing tradition of chivalry, it is not surprising that professional secrecy for all concerned with the art of healing, nurses as well as doctors, is imposed by law. During the recent rioting in Paris, the wounded among the civilians were cared for in the public hospitals as well as at home. No complete census will ever be made of these casualties, and it is unthinkable that any official would dare to challenge the combined authority of the law and public opinion by coercive measures infringing the obligation of medical secrecy. Public opinion has a very fine tradition as well as instinct behind it in this matter, and one of the most dramatic events in the history of medicine and the right of sanctuary concerns Jean-Dominique Larrey, the heroic surgeon of the Napoleonic wars of whom Napoleon wrote in his will: "C'est l'homme le plus vertueux que j'aie connu." During the revolution of 1830, Larrey, then about 64 years old, found himself busy at the Gros-Caillou Hospital in Paris caring for the wounded. His prestige was such that, as he proceeded to his work, the rioters cleared a passage for him, and the troops concerned with the maintenance of order presented arms as he went by. One evening the rioters swept up to the Gros-Caillou Hospital in search of wounded members of the Royal Guards. Larrey ordered every door to be flung open, and as the rioters surged forward he faced them squarely with: "Que voulez-vous? Mes blessés? Ils sont à moi, allez-vous-en!" And they did.

I am, Sir, yours faithfully,
April 2nd. YOUR PARIS CORRESPONDENT.

To the Editor of THE LANCET

SIR,—The political crisis has affected Austrian practitioners in many ways. All Viennese doctors connected with the Schutzbund (the socialist armed force) are in prison, and doctors attending wounded socialists are liable to be imprisoned unless they notify the police of the names and addresses of the patients.

With regard to the position of Jewish doctors, in August 1932 I found that Jewish practitioners had been excluded from the staff of the Kinderklinik, while all Viennese doctors have to fill in papers giving their nationality and religion, and the dates since which both have been held. Jewish medical men are being removed from their existing hospital appointments in many parts of Austria.

Those of us who have seen the excellent public health services in Vienna—housing schemes, day nurseries, swimming baths, and children's hostels—must especially deplore that the chief promoter of all these measures, Prof. Julius Tandler, is now in prison. He returned from safety in Czechoslovakia to Vienna knowing the fate that was in store for him.

I am, Sir, yours faithfully,
Eastdean, April 2nd. STELLA CHURCHILL.

THE THEORY OF VISION

To the Editor of THE LANCET

SIR,—Though all are agreed that the cones of the retina are the percipient elements, no one has shown how the transparent colourless cones can be directly stimulated by light or form a basis for colour perception. Direct stimulation does not agree with the laws of photo-chemistry. According to Grotthus's law no effect can be produced by light unless it is absorbed. Stimulation of the cones, therefore, must be indirect and all the facts point to the view that it takes place through the photo-chemical decomposition of the visual purple.

I am, Sir, yours faithfully,
F. W. EDRIDGE-GREEN.
Board of Trade, S.W., March 28th.

MENORRHAGIA CURED BY SPLENECTOMY

To the Editor of THE LANCET

SIR,—At the meeting of the North of England Obstetrical and Gynæcological Society reported in your issue of March 24th (p. 632) Mr. Carlton Oldfield described the case of a woman, aged 25, who suffered from menorrhagia for three years, with resulting anæmia, and was cured by splenectomy performed by Lord Moyniham. The case was probably one of essential thrombocytopenic purpura hæmorrhagica, although, it was stated, there had never been a purpuric rash or bleeding from other mucous membranes. The low platelet count and prolonged bleeding time, together with the excellent effect of splenectomy, which was followed by the large increase of platelets and a return of normal bleeding time, are most suggestive. The patient remains in perfect health nine months after the operation and menstruation has become normal.

This case reminds me of one I published in the *Proceedings of the Royal Society of Medicine* (clinical section) eight years ago.

A woman, aged 28. suffered from very severe menorrhagia which necessitated her frequent admission to hospital. In one instance the bleeding had continued for several weeks and her red cells had fallen to just over two million. The thrombocytes were almost absent, the bleeding time 15 minutes, and the capillary resistance test strongly positive. The spleen was not palpable. Her temperature went up to 104° F. Nothing proved of any use except blood transfusion. After her full recovery I asked my colleague, Mr. Rodney Maingot, to perform splenectomy at the Royal Waterloo Hospital, and within a few days the thrombocytes had increased to over a hundred thousand, the bleeding time became normal, and the capillary resistance test negative. As a matter of fact, the bleeding time became normal shortly after the operation. Splenectomy was performed eight years ago and menstruation has been normal ever since, while her general condition is excellent, indeed she now enjoys robust health.

I am not at all surprised to learn that in Mr. Oldfield's case "the bleeding time became normal immediately after operation"; for in two of my own cases of essential purpura hæmorrhagica, in which there had been bleeding from the gums and nose for weeks without treatment availing, the loss of blood ceased within a few minutes of the splenic vessels being tied.

I am, Sir, yours faithfully,

April 2nd. BERNARD MYERS, M.D., F.R.C.P.

DUST FROM TARRED ROADS

To the Editor of THE LANCET

SIR,—I am instructed by my association to draw your attention to the title to Dr. Campbell's note on p. 233 of your issue for Feb. 3rd.

The substance of the note does not lead to the inevitable conclusion that cancer will arise from the action of dust from tarred roads; yet there is a great danger that readers seeing the title, "Note on the experimental production of cancer by dust obtained from tarred roads," will be led to believe, unless they examine the subsequent reading matter critically, that the dust from tarred roads is responsible for cancer in human beings, and this may cause much unnecessary prejudice against roads treated with British tar.—I am, Sir, yours faithfully,

R. MURDIN DRAKE,
For General Manager, The Association of British Chemical Manufacturers.

166, Piccadilly, W., March 23rd.

PARIS

(FROM OUR OWN CORRESPONDENT)

ENTERIC FEVER IN MARSEILLES

ACCORDING to Prof. H. Violle, the mortality from typhoid in Marseilles in 1931 was 15·7 per 100,000 inhabitants, while the corresponding figures for Paris, Berlin and London were 4·8, 0·8, and 0·5 respectively. The notification of the causes of death in Marseilles being notoriously defective, the true state of affairs in the town is assuredly even worse than the official returns suggest. Little wonder, therefore, that the last annual meeting of the Medical Society of Marseilles was devoted to this subject, and that it was discussed on three different dates (Feb. 15th, 21st, and 28th). The heads of Prof. Violle's indictment were several: lack of sewers in parts of the town and its suburbs; chlorination of drinking water in the central area only; pollution of the coast line aggravated by the tideless state of the Mediterranean; and consequent infection of shellfish. Prof. D. Olmer stated that about 98 per cent. of the enteric fever in Marseilles was due to the typhoid bacillus, only 1·4 per cent. being due to paratyphoid B, and 0·2 per cent. to paratyphoid A. According to the same authority, the effect of inoculation against the disease is reflected in the relatively high morbidity and mortality in women, few of whom have enjoyed its benefits. He has not only found shell-fish responsible for an imposing proportion of cases, but has also learnt to regard typhoid of such origin as more serious than typhoid contracted in some other way (mortalities of 21 and 12 per cent. respectively). Shell-fish typhoid has a comparatively short incubation period; there is a preliminary stage of slight gastro-intestinal upset with or without jaundice; diarrhœa, hæmorrhages, and perforation are common; and the various stages of the illness tend to run into one another as if the rhythm were accelerated. Its severity may be attributed either to massive infection or to coincident infection—by *B. coli*, for example. With regard to treatment, Prof. C. Mattei and Dr. Isemein recommended Rodet's specific serum, which they say is always harmless and often effective even in desperate cases. Other speakers discussed the value of bacteriophage and found it doubtful. A more favourable opinion was expressed of the transfusion of the blood of a healthy person recently inoculated against typhoid and paratyphoid fever. With regard to preventive measures, typhoid inoculation by subcutaneous injection emerged from the discussion with commendation, whereas Besredka's method of oral immunisation was dismissed as uncertain, as being effective only for a few weeks, and as giving a false sense of security.

THE PHYSICIAN ATTENDS ON HIMSELF

A correspondent in *Concours Médical* for March 18th seeks advice. A war pensioner suffering from pulmonary disease, he has been in the habit of signing his own prescriptions, and was proceeding blithely in this course when a colleague told him that such autotherapy was against the regulations. The legal adviser to *Concours Médical*, Dr. Boudin, reassures him. It appears that according to a law of 1919 every war pensioner is entitled to choose his own doctor; how then could those who administer this law stultify it by discriminating against the doctor most likely to take and interest in the case? A judgment of the law courts in 1920 also rules that a properly qualified doctor is as free to use dangerous drugs for his own treatment as for that of anyone else. It seems therefore that no formal objection can be raised to the medical pensioner's prescriptions for himself, even when the chemist's bill is paid by the State. But when it comes to the charging of a fee for the medical care he renders to himself, the matter is somewhat different. The French Ministry of Pensions holds that such charges are not permissible; Dr. Boudin, on the other hand, while admitting that there is something "inelegant" about them, does not believe they are strictly illegal. There is common sense as well as a legal aspect to this problem. A prescription can be scrutinised and analysed; and there are limits to the amount of drugs that even the most receptive patients can accommodate. But medical care, with appropriate advice, is a far less tangible commodity; and the medical pensioner, free to rate the visions of his head upon his bed as consultations worthy of remuneration, might well experience some difficulty in maintaining his normal ethical "elegance" as he attempted to assess the value of abstract thought in terms of hard cash.

MARGARINE IN DISGRACE

A report by Prof. L. Hugounenq to the French Academy of Medicine on Feb. 27th dealt with margarine as a food, its dangers to health, and its inadequacy as a substitute for butter. Many of the failings of margarine are already well known, but there have previously been few indictments of it so sweeping and sustained. Its faults, he said, include a comparative lack of digestibility, a deficiency or lack of vitamins, and the absence of acids which give butter an attractive smell and taste. Butter also contains phosphorus which is not to be found in the materials from which margarine is made. In response to this report the following resolution was adopted: "The Academy, considering that certain margarines provoke digestive troubles in certain persons that these troubles are undoubtedly due to faulty conditions of manufacture and purification, that certain margarine factories elude the supervision and control provided by the law, that margarine is a substitute for butter which does not, however, contain all the elements of natural butter (vitamins and fatty acids) recommends that all undertakings, without distinction, which deal with animal fats intended for food, should be under supervision and inspection and subject to full legal control in the interests of public health."

OBITUARY

DAVID LEES, M.B., Ch.B., F.R.C.S. Edin., D.S.O.

We regret to record the death of Dr. David Lees, surgeon to the Royal Infirmary, Edinburgh, which occurred on March 25th after an operation, in his fifty-fourth year.

David Lees was born in Tarbolton, the son of Mr. Robert Lees, of Lagg, a veterinary surgeon, and was educated at the Ayr Academy and at the University of Edinburgh. He graduated as M.B., B.Ch. in 1907, and was a distinguished student, becoming later resident house surgeon at the Royal Infirmary and house physician at the Royal Maternity Hospital, Edinburgh. He was for a time assistant medical officer at the Bangour Mental Hospital, and then for four years served in France with various units, being several times mentioned in despatches and obtaining the D.S.O. in 1917. In 1918 he obtained the diploma of F.R.C.S. Edin., and was elected surgeon to the Royal Infirmary, and consulting surgeon for veneral diseases to the Royal Maternity Hospital. Of these diseases he made a particular study, his advice being sought in many directions; he was, for example, delegate of the British Social Hygiene Council to Cyprus and to India during 1926–27, with the responsibility of advising various governments on systematic methods of dealing with venereal disease. He had already written largely and practically on the subject, producing papers on vaccine therapy in gonorrhœa, and writing the article on the Vesiculæ Seminales in the Encyclopædia Medica; and in 1927 his book entitled "Practical Methods in Diagnosis and Treatment of Venereal Diseases" went speedily through two editions. This book brought together in readable form the latest ideas and the most recent technique. Some of the plates should have historic value, as they picture syphilitic rashes of which the present-day student sees little owing to effective therapy. And Lees's wide personal experience enabled him to make useful generalisations about various kinds of therapeutic measures. At the B.M.A. meeting of 1927 he recorded observations on 6000 cases of syphilis treated with bismuth, and recorded his own opinion that, valuable as it was for its ease and safety of administration when organic disease was present, bismuth should always be combined with arsenic, except possibly in pregnancy. Brought in contact in the Edinburgh clinic with a highly floating population Lees was early and strongly impressed with the need to follow up the treatment of venereal disease to a successful conclusion if public health was to be efficiently served. He was prominently associated with the compulsory measures embodied a few years ago in the Edinburgh Corporation Bill, believing that, without some kind of assurance of continuous treatment, many sufferers from venereal diseases would neither be cured themselves nor be prevented from remaining a danger to the community.

Lees was a good teacher, emphatic and picturesque, speaking with conviction of things of which he had personal knowledge, and how valuable his services were at the Edinburgh Infirmary is well set out in the following estimate from a distinguished colleague:—"There are certain people who occupy positions which are peculiar and unique because they have created them themselves. David Lees was such an one. His dynamic personality, combined with his obvious sincerity, enabled him to get things done according to his own well-considered plans. His department could not be thought of apart from himself as it was the expression of his character and his energy. His broad interest in medicine made his opinion on all matters connected with his specialty of peculiar value, and his medical and surgical colleagues availed themselves freely of his ever-ready help. Whilst clear-headed and dogmatic in his views, he was singularly free from all conceit, and a saving sense of humour preserved harmony whenever a clash of opinions threatened discord. His interests were widespread; a keen sportsman he took an active part in the athletic side of university life. As secretary of the Medico-Sociological Club he was the moving spirit in promoting discussions on broad public questions in their relation to medicine. It is, however, as an enthusiastic, helpful, and loyal colleague that he will be missed the most by his medical associates in Edinburgh. He had made such a bold and characteristic niche for himself that it is difficult to see how it can be filled. He has left us a very vivid picture of how a man of character and personality may create for himself and his specialty a position of undisputed authority and importance."—*D. P. D. W.*

Another personal friend adds to the picture with these words :—"David Lees had a robust personality; opposition did not damp but rather stimulated him to renewed attempts to carry his point. His arguments were not inspired by a subtle diplomacy but by confidence that logic demanded the acceptance of the conclusions to be drawn from the available evidence. If any were irritated by this attitude, they were forced to respect the man, and his influence in the development of his specialty was indubitable, even though he failed to carry through one project which he had most at heart, the making in Scotland of venereal diseases notifiable. In the pursuits of his leisure David Lees presented the same almost boundless energy. A keen golfer, he was so much interested in the encouragement of golf as a game for children that he often gave up his own sport, when on holiday, to organise competitions for boys and girls. His cheerful good nature will be greatly missed at the northern golfing resorts where he spent his summers. His own son shows a remarkable aptitude for the game."

David Lees leaves a widow and one boy.

SAMUEL LODGE, M.D., B.S. Durh., O.B.E.

THE death occurred on March 19th at his residence in Harrogate of Dr. Samuel Lodge, well known in Bradford and Halifax and outside his immediate circle as a specialist in diseases of the eye and ear. He was 68 years of age.

Samuel Lodge was a native of Bradford, the son of a medical man of the same name, and received his early education at the city Grammar School. He entered St. Thomas's Hospital as a medical student and attended courses at various times at Leeds and at the University of Paris. He graduated as M.B., B.S. Durh. in 1887, and was for a time medical and surgical assistant at the Royal Infirmary, Newcastle-on-Tyne. He shortly afterwards began to specialise in the subjects in which he made his considerable name, was elected surgeon to the eye, ear, throat, and nose department of the Halifax Infirmary, and surgeon to the Bradford Royal Eye and Ear Hospital. During the war he was medical officer to the 6th Battalion of the West Yorkshire Regiment, being already a surgeon-major in the Volunteers, and did excellent organising work, receiving for his services on the Army Medical Boards in Bradford and Leeds the O.B.E. Dr. Lodge's connexion with the Halifax Infirmary extended over nearly a quarter of a century, but he had lived recently in semi-retirement. He leaves a widow and four sons, three of whom are in the medical profession, and one of whom succeeded his father at the Halifax Infirmary. Another son, who died recently, was ophthalmic surgeon to the Leeds Infirmary.

SYDNEY GUY BILLINGTON, M.B., B.S. Lond., F.R.C.S. Edin.

THE death occurred on March 17th of Dr. Sydney Guy Billington, who had undertaken much independent research in the attempt to discover biochemical remedies which might be of value in several conditions —notably, influenza and rheumatism and malignant disease. He received his education at the Birmingham medical school, took the English double qualification in 1910, and in the same year graduated at the University of London as M.B., B.S. He later acquired the diploma of F.R.C.S. Edin. He was a successful student, filled house appointments at the Queen's Hospital, Birmingham, and later became resident pathologist at the General Hospital, Birmingham, while he held the same post for a time at Wolverhampton General Hospital. For the last 17 years he was very interested in promoting the use of "Billington's Antibody," and published, in certain quarters, reports on the use of the remedy purporting to show its value in many conditions, in malignant disease among others. He was unable to obtain the support which he considered his due from members of the medical profession in regard to either his theories or his results; his industry and enthusiasm were undoubted, and certain supporters of his views consider that his work, or some of it, may yet receive more consideration than it did during his lifetime.

MENTAL AFTER-CARE ASSOCIATION

Lord Wakefield of Hythe presided at the annual meeting held on March 20th at the Haberdashers' Hall, when Mr. L. G. Brock, chairman of the Board of Control; Dr. Nathan Raw, Lord Chancellor's visitor in lunacy; Dr. Reginald Worth, chairman of the Association, and Mr. J. M. Oakey, the treasurer, spoke of the activities of a year in which 2865 had been helped. The Association boards out patients in cottage homes for a period of convalescence, arranges residence for them during attendance at clinics, gives them grants of money or relief in kind, gives maintenance while work is being found, obtains employment suitable to their abilities, supplies clothing, tools, &c., necessary for employment, and, generally speaking, acts as a personal friend with sympathy, understanding, guidance, and help. The council reported assistance rendered to many societies and hospitals which had referred difficult cases to them. During the year a large number of old patients had applied for help and advice, an encouraging feature of the work being the way in which those who had once been assisted turned to the Association in their later troubles. Help given at the right time is responsible for averting relapses and consolidating recoveries; in 1933 the Association dealt with 591 "pre-care" patients, the great majority of whom were prevented from becoming patients in a mental hospital. New developments in the Association's work include coöperation with the L.C.C. in the supervision of patients leaving its mental hospitals, and the supply to county and other authorities of social workers. The treasurer described the ratio of administration expenses to revenue as one of the lowest of any benevolent organisation in the country. The secretary of the Association is Miss Vickers, from whom particulars can be obtained at Church House, Dean's Yard, Westminster.

NEWCASTLE ROYAL INFIRMARY: ANNUAL REPORT. The Royal Victoria Infirmary, Newcastle-upon-Tyne, last year admitted 12,842 new in-patients, whose average stay was 15·8 days. This was an increase of 590. There were 110,708 out-patients. With the opening of a special new block of buildings for the treatment of orthopædic cases, and the heightening of two pavilions to add new wards, and thereby replace the two wood-constructed wards erected temporarily during the late war, 54 beds have been added to the bed strength, bringing the present complement of beds in the voluntary side of the hospital up to 645. The new orthopædic building cost £31,000. It is hoped that the additional beds will make a sensible impression upon the waiting-list of nearly 2000. There were 1108 motor traffic cases, of which 416 were admitted, involving an average daily occupation of 18 beds. The total cost was £2413, of which £444 was received from insurance companies. On an average only 30 per cent. of the accounts submitted by the hospital have been paid by the companies.

Since the beginning of this year the Royal Victoria Infirmary has benefited by five bequests of the total value of £4900.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Easter Adjournment

ON Wednesday, March 28th, the House of Lords adjourned for the Easter recess until Wednesday, April 11th. The Royal Assent was given to a number of Acts, including the Rural Water Supplies Act, the Indian Pay (Temporary Abatements) Act, and the Mining Industry (Welfare Fund) Act.

The House of Commons adjourned on Thursday, March 29th, for the Easter recess until Monday, April 9th.

Bills Advanced

In the House of Lords on March 27th a Bill to deal with betting and lotteries was introduced and read a first time. In the House of Lords on March 28th the South Devon and East Cornwall Hospital, the Plymouth Royal Albert Hospital, and the Devonport and Central Hospital Bills were introduced and read a first time. In the House of Commons on March 28th the Birmingham United Hospital Bill was read a first time.

Poor Law (Scotland) Bill

In the House of Commons on March 27th Mr. SKELTON (Under-Secretary of State for Scotland) moved the second reading of the Poor Law (Scotland) Bill. He said that the Bill was only a step, though an indispensable step, to a full and comprehensive modern poor-law statute. The function of the present Bill was to make amendments of the law, most of which were long overdue. The Bill provided that in the case of an able-bodied unemployed man there should be an opportunity, where it seemed desirable, that proper work should be done in return for relief. It also made it possible for the poor-law authority to provide the means for training and instruction. It dealt with poor-house discipline, questions connected with discharge, and a novel feature with regard to taking to suitable institutions a certain type of aged and infirm persons. Clause 4 of the Bill provided that a local authority should, if required by the Department, provide suitable and separate poor-house accommodation for each or any of such classes of inmate as might be prescribed by regulations made by the Department. At present the Department of Health for Scotland had no powers definitely of stimulating local authorities to proceed with the work of improving the poor-houses. Modern methods and the modern point of view demanded that, where possible, there should be proper segregation in their own interests of the classes of people who composed the different types of those requiring assistance. Clause 9 provided for the removal, under full and proper safeguards, to a suitable hospital or other institution of aged and infirm, or physically incapacitated persons who were unable to devote to themselves, or to obtain from other persons, proper care and attention. The procedure would be that on a certificate by a medical officer application might be made by the relieving authority to the Sheriff, who would have to be satisfied that there was a suitable institution to which the person could go. An order could then be made, which in no case lasted for more than three months, for the removal of the aged or infirm person to a suitable institution. Clause 10 gave a new right to the poor of Scotland—namely, that the first 5*s.* of friendly society sick pay should be disregarded in the assessment of their relief. It also incorporated a provision which the Scottish poor had enjoyed up to now—namely, that the first 7*s.* 6*d.* of National Health Insurance benefit should be disregarded. It was provided that a casual poor person should not be entitled to discharge himself from a poor-house before 9 o'clock in the morning of the second day following admission. It was important that when a vagrant or casual poor person was in an institution the opportunity should be taken to cleanse them and their clothing. That was a public health duty and was beneficial to the casual or vagrant person.

Mr. MILNE said that in 1904 a departmental committee reported on the medical relief of the poor. The report stated that in one poor-house they found an inmate undergoing 12 hours' confinement in a cell that was not provided with a seat. It was absolutely dark and without ventilation or heating. The temperature at the time of the visit of the committee was only a few degrees above freezing-point, and other cells were in much the same condition. If abuses had occurred in the past, what assurances had the House that abuses might not occur in future? Another departmental report concerning, not Scotland, but the poor-law system in England, and dated 1930, stated that in a certain number of casual wards the conditions now existing were infamous and intolerable. Some of the committee had visited wards where two men were locked in a small cell that was built for one person, and kept there in darkness for 12 or 13 hours. The point was that that was possible in England in 1930. An unofficial report from a well-informed source stated that some of the poor-houses in Scotland were most admirable. He made no charge against the administration of the Scottish poor-law authorities, who carried out their difficult duties with zeal, efficiency, and humanity, but they had not always the accommodation necessary for detention, much less for solitary detention. In one place the unofficial report stated that a small public assistance shelter had no bath, and the sleeping accommodation was poor. In another case, in a lodging-house where casuals were sheltered at the public expense, it was reported that " the beds were swarming with vermin . . . crowded together, and the floor was filthy." The first thing to do was to provide suitable accommodation.

Mr. BUCHANAN urged that the power to remove old people was one that was capable of the worst abuses and should be removed from the Bill. At present, generally speaking, the old people went to the public hospitals. The chief indictment against the hospitals was that they were not made attractive. The authorities ought to start to build decent houses away from the taint of the poor-house for the old people to live in, then they would go in and there would be no need to exercise compulsory powers.

The Bill was read a second time, and committed to a Standing Committee.

Miners and Silicosis

In the House of Commons on March 29th, on the motion for the adjournment for the Easter recess,

Mr. D. GRENFELL called attention to the wide prevalence of silicosis. He said that an inquiry was held in 1925 by the Mines Department. A report was made to the Department confirming the belief that silicosis in this country was identifiable with miners' phthisis, which had caused such ravages among the South African miners and for which special legislation was provided. Since 1925 there had been investigations and references to departmental committees, but it was not until 1929 that a regulation was issued by the Home Office acknowledging the liability of employers to pay compensation to the victims of this disease. Silicosis was spreading to an alarming extent in the mining industry. The Secretary for Mines must have been surprised at the result of the inquiries made at his (Mr. Grenfell's) instance a short time ago.

It was reported that during a certain period there had been certified in the mines of this country 400 people so disabled as readily to obtain certification. He believed that that figure represented only a small part of the incidence of the disease. He dreaded to estimate the number of people who would become certified year after year as time went on. He urged the Home Secretary to pursue those inquiries which were taking place by the medical staff of his department working in collaboration with a special medical man appointed by the Mines Department. He would like the two Ministers to expedite those investigations with all possible speed. Silica, he was convinced, was not the only mineral which was responsible. There was in the silicious rocks an element called sericite which played a very large part in the production of this disease.

In certain parts of the coalfields the presence of silica and the percentage of it did not account for such widespread prevalence of the disease as in other areas. For example, the figures given by the Inspector of Mines showed that of 424 cases in the whole of Great Britain 386 had been certified in South Wales; that was to say that in one coalfield, where there was 25 per cent. of the mining population, 80 per cent. of the silicosis cases were found. The incidence was higher in certain parts of South Wales than over the whole coalfield on an average. There were special areas where the incidence was exceptionally high, and that could not be explained by varying degrees of contamination with silica, but must be ascribed to some other cause.

Not only was he urging that these investigations should be actively pursued, but no time should be lost in adopting preventive measures. Medical science was quite helpless in this matter. No medical treatment could help these people who had contracted the disease or relieve their condition in the slightest. He would like to see a "safety first" campaign directed to known preventive measures. He was not satisfied that any effective dust-trap had yet been invented. Nor did he think that an effective respirator had been produced which could be made portable and which people could be obliged to wear.

Mr. GRENFELL said he would like to make these preventive measures automatic—not merely dust-proof, but fool-proof—with no possibility of pollution of the air taking place; and the only way that that could be done was to lay the dust at the spot where it was made before it emerged into the atmosphere. To do that effectively a system of wet drilling was the only one which commended itself to him, and there was no reason that he was aware of why an Order should not be made by the Secretary for Mines. He believed that hundreds of lives would be saved if wet drilling were compulsorily imposed.

After further debate, Sir JOHN GILMOUR (Home Secretary) said that one of the great administrative difficulties in dealing with the question was to find absolutely sure and certain ground upon which they could work. Opinions were held by some that the use of water in dealing with drills or laying dust was considered to be a solution. If it was as simple as that they could feel that they could at once take a step forward, but he was informed by those who had studied the problem that while there might be much to be said for using part of this system it was really not conclusive. He thought it was true that they were only working on the fringe of these problems, but he understood that the scientists had been working with a common purpose and with all possible expedition to try, if possible, to improve matters.

He understood, for instance, that there was a mask or respirator which shortly would be available for trial. As to the question of compulsion, they all knew the difficulties of getting a workman unaccustomed to these appliances to make use of them consistently. It was necessary that the beneficial results of such appliances should be explained to the workmen. The Home Office realised that there were difficulties in the width of the source from which infection could come. He understood from those who had investigated the matter that while it was true that sericite was found in certain cases to have deleterious results it had never been established that any case had been proved in which at the same time silica had not been present. If he was right, while sericite might be a contributory cause of the disease, it was not a primary cause. He could assure the House that the Home Office and the Ministry of Mines were endeavouring to investigate the problem. Undoubtedly better ventilation in the mines was of immense importance. In regard to the problem of dust in mines, methods for limiting the range of the explosion were being investigated from all practical sides. If there was anything which could be done to limit the period of time within which it was possible to decide whether compensation was payable he would look into it with the greatest sympathy. Although knowledge of this problem was increasing, and more people might be coming into the arena to whom they could apply for help, the fact remained that this question could only be decided by those who were really conversant with the problem.

The Government, Sir John Gilmour concluded, were at present in communication with the mine owners upon this problem and were actively discussing the aspects—some of them new aspects—upon which quite clearly there were division of opinion on which science had not yet definitely come to a conclusion. He hoped that perhaps at a later stage in the session he might be in a position to say something further.

HOUSE OF COMMONS

TUESDAY, MARCH 27TH

State-aided Houses

Mr. KIRKWOOD asked the Secretary of State for Scotland how many State-aided houses were under construction in Scotland in March, 1933; the number under construction at present; and what was the cause of the decline.—Mr. SKELTON, Under-Secretary of State for Scotland, replied: The number of State-assisted houses under construction by local authorities and private enterprise in Scotland at March 31st, 1933, was 23,503. Figures for March are not yet available. For purposes of comparison I give figures for February of 1933 and 1934. These were 22,315 and 16,446 respectively. With regard to the second part of the question, the hon. Member will recollect that local authorities are at present concentrating upon programmes for slum clearance. These are not sufficiently advanced to be reflected in the houses under construction at Feb. 28th, but the tenders approved for new construction are now showing the effect of this activity, the number of tenders approved for February, 1934, under the Act of 1930, being 1122 compared with 334 in February, 1933.

Shortage of Water-supplies in Scotland

Mr. KIRKWOOD asked the Secretary of State for Scotland how many local authorities in Scotland had reported a shortage of water-supplies; how many villages had no proper supply, even apart from the drought; what action the Government proposed to ensure a supply for all parts of Scotland; and if he was aware that in the vicinity of Loch Katrine there were hamlets and villages which had been short of water-supplies since last summer.—Mr. SKELTON replied: As regards the first two parts of the question, of the local authorities who have so far replied to the inquiry made by the Department of Health in January last, 50 town councils and 9 county councils have reported a shortage of water in their areas during 1933. The replies from the 9 county councils referred to shortages in 65 special water-supply districts, and 43 villages without publicly owned supplies. As regards the third part, the department propose, immediately the Bill at present under consideration in another place is passed, to invite applications from local authorities who desire to participate in the grant to be made available for the improvement of rural water-supplies. As already stated in the House, the Government have under consideration further steps for dealing with an emergency due to the drought should circumstances so require. As regards the last part of the question, I am informed that the only village in the vicinity of Loch Katrine which has been short of water since last summer is Brig o' Turk, and that this case is at present receiving the attention of the county council of Perth.

Medical and Nursing Services in Scottish Islands

Mr. T. B. W. RAMSAY asked the Secretary of State for Scotland if he was aware that there were no hospitals, nursing, or maternity homes in the islands of Harris, North Uist, Benbecula, and Barra, or the smaller islands adjacent thereto, with the exception of a casual sick house in Harris; if he was aware that the medical services for the said islands were performed by visiting doctors and nurses; and what provision was made for sudden and serious illnesses, accidents, and maternity cases in these islands.—Mr. SKELTON replied: The answer to the first part of the question is in the affirmative. The medical and nursing services are provided by doctors and nurses actually resident on the islands named. As regards the last part of the question, arrangements are made wherever practicable for the removal of patients from Harris to the hospital at Stornoway, and from the other islands named either to Oban or Glasgow. Cases from Benbecula are sometimes treated in the private hospital on South Uist. The doctor at Benbecula was specially selected for appointment because of his surgical knowledge and experience. In urgent cases, as an alternative to the removal of the patient, the surgeon from Stornoway, accompanied if need be by a nurse, may travel to his home.

Small-pox at Blackburn

Mr. Groves asked the Minister of Health whether any of the Blackburn small-pox patients had been vaccinated before removal to hospital with small-pox: and, if so, how many days before such removal was the vaccination performed in each case.—Sir Hilton Young replied: Five patients were vaccinated shortly before removal to hospital. Two of these were vaccinated during the incubation period of the disease six and ten days respectively before removal. Three were vaccinated after the illness had begun—one on the day of removal, one the day before removal, and the third four days before removal.

Medical Examination of School-children

Mr. Groves asked the Parliamentary Secretary to the Board of Education whether any regulations existed that required the presence of a female nurse during the medical examination of school-children.—Mr. Ramsbotham replied: The Board of Education have not made any regulation requiring the presence of a nurse during the medical examination of school-children, but it is the general practice for a school nurse or some other woman helper to be present.

Sickness Benefit and Housework

Mr. Parkinson asked the Minister of Health if he had authorised the decision that when an insured woman, who was in receipt of national health insurance benefits, was certified by a medical officer as being able to do housework though unable to follow her usual occupation, her benefits should cease, even though she intended to resume her own occupation as soon as her health would permit.—Sir Hilton Young replied: There is no general decision that an insured woman who, though unable to follow her usual occupation, is able to do housework, is to be treated as not entitled to sickness or disablement benefit. An approved society would not ordinarily regard such a woman as disentitled to benefit pending her early return to her normal employment, but in the case of a woman who is the domestic head of a household and for whom, accordingly, the performance of household duties is in the nature of an alternative to her industrial employment, fitness for the former as well as for the latter form of work would properly be taken into consideration. Societies have been informed that it is their duty to consider every such case on its merits, and any woman who is dissatisfied with the decision of her society is entitled to appeal in accordance with the rules of the society.

WEDNESDAY, MARCH 28TH

New Formulæ for Surgical Spirit

Miss Horsbrugh asked the Secretary to the Treasury the reason for the withdrawal as from March 15th, 1934, of the formula permitted during the past years for the manufacture of the preparation of methylated spirit known as surgical spirit and the substitution of two new alternative formulæ.—Mr. Hore-Belisha replied: The object was to achieve a still higher degree of unpalatability in the product.

THURSDAY, MARCH 29TH

Medical Examination of Motorists charged with being Drunk

Mr. Isaac Foot asked the Home Secretary if he had now been able to consider the remarks of Mr. Justice Swift at the recent Liverpool assizes as to the examination of persons charged with being intoxicated whilst driving motor-cars; and if he proposed to amend the existing practice relating to the examination of such persons by doctors called in by the police.—Sir J. Gilmour replied: I have had this matter under consideration, but at the moment I am not in a position to make any statement.

Food Standards

Captain Erskine-Bolst asked the Minister of Health when the report of the departmental committee on food standards would be available.—Sir Hilton Young replied: The report has just been presented to me, and I am giving instructions for its publication as soon as possible after Easter.

MEDICAL NEWS

Society of Apothecaries of London

At recent examinations the following were successful:—

Surgery.—A. J. L. Bolger, Univ. of Liverp.; J. L. Freer, Guy's Hosp.; J. C. Harvey, St. George's Hosp.; C. W. O'Donoghue, London Hosp.; F. D. Paterson, St. Mary's Hosp.; J. D. Taylor, Univ. of Manch.; and T. H. N. Whitehead, Univs. of Oxf. and Leeds.

Medicine.—A. J. L. Bolger, Univ. of Liverp.; A. C. E. Cole, Univ. of Camb. and St. Mary's Hosp.; R. Frankling, Guy's Hosp.; J. Lipschitz, Westminster Hosp.; B. C. M. Palmer, Univ. of Camb. and Guy's Hosp.; and T. H. N. Whitehead, Univs. of Oxf. and Leeds.

Forensic Medicine.—A. J. L. Bolger, Univ. of Liverp.; M. T. Curran, Univ. of Leeds; B. C. M. Palmer, Univ. of Camb. and Guy's Hosp.; H. Paroulakis, Univ. of Innsbruck and St. Mary's Hosp.; J. H. Playne, St. Mary's Hosp.; F. W. Treadwell, Univ. of Birm.; and T. H. N. Whitehead, Univs. of Oxf. and Leeds.

Midwifery.—A. J. L. Bolger, Univ. of Liverp.; R. N. Crossley, Univ. of Manch.; M. T. Curran, Univ. of Leeds; B. Dayal, Univ. of Durham; J. H. Playne, St. Mary's Hosp.; and T. H. N. Whitehead, Univs. of Oxf. and Leeds.

The following candidates, having completed the final examination, are granted the diploma of the society entitling them to practise medicine, surgery, and midwifery: A. J. L. Bolger, A. C. E. Cole, B. Dayal, R. Frankling, J. L. Freer, J. C. Harvey, J. Lipschitz, B. C. M. Palmer, J. D. Taylor, and T. H. N. Whitehead.

Honours for Sir H. Wellcome

The American Pharmaceutical Association has awarded its Remington medal, which is conferred for distinguished service to pharmacy, to Sir Henry Wellcome, F.R.S., founder of the Wellcome Research Institution and head of Burroughs Wellcome and Co. Apart from the numerous laboratories of the establishments of his firm, Sir Henry has established a number of research laboratories and *museums which are coördinated as the Wellcome Research* Institution. The new building of this institution occupies a site in the Euston-road, London.

The President of the French Republic has conferred upon Sir Henry the Cross of Chevalier of the Legion of Honour.

Royal College of Surgeons of Edinburgh

At recent examinations the following candidates were successful:—

L.D.S.

L. B. Corner, W. R. Weatherston, T. H. Thompson, R. J. E. Derwent, W. H. Charlton, R. O. Walker, A. E. Thompson, A. V. Robson, J. H. Quin, Frederick Gilhespie, W. R. D. Boyd, and G. A. McC. Durran.

Charing Cross Hospital Nurses' Hostel

It has been decided to complete the original scheme for this hostel at Haverstock Hill at a cost of £30,000. It will then be possible to release much space in the hospital for paying patients. By the generosity of the Daimler Company the nurses are carried to and fro in two large motor coaches.

University of Liverpool

On Friday, May 11th, the University will celebrate the centenary of the incorporation of its medical school. It is proposed to confer the honorary degree of D.Sc. on Dr. Henry Dean, professor of pathology in the University of Cambridge, and Master of Trinity Hall; Sir Thomas Lewis, F.R.S., physician to University College Hospital, London; Mrs. May Mellanby, investigator for the Medical Research Council; and Mr. Wilfred Trotter, F.R.S., surgeon to University College Hospital, London. The honorary degree of LL.D. will be conferred on Prof. William Blair-Bell, who held the chair of obstetrics and gynæcology in the University from 1921 to 1931, and was first president of the British College of Obstetricians and Gynæcologists; Prof. Henry Briggs, the previous holder of the chair (1898–1921); Dr. H. R. Hurter, past president of the Liverpool Medical Institution; and Dr. W. S. Paget-Tomlinson, lately chairman of the public health committee of Westmorland.

Gift for Radiology at Middlesex Hospital

Mr. E. W. Meyerstein has given £30,000 for the establishment of a new department of radiology.

University of Glasgow

At a graduation ceremony to be held on June 20th the honorary degree of LL.D. will be conferred on Dr. René Leriche, professor of clinical surgery in the University of Strasbourg.

German Radiological Society

The twenty-fifth congress of this society will take place at Baden-Baden from April 14th to 16th. Particulars may be had from Dr. Kloiber, Röntgenabteilung des Städtischen Krankenhauses, Baden-Baden.

Surgical Treatment of Tuberculosis

At the annual meeting last week of the governors of the Brompton Hospital for Consumption, Lord Derby said that whereas 12 years ago there were 66 cases of surgical treatment and one visiting surgeon, the hospital now has two surgeons and two assistant surgeons on the staff, and the surgical operations last year reached the record total of 1122. The daily average of occupied beds was 464.

Westminster Hospital Appeal

Westminster Hospital has succeeded in raising within five months the £100,000 required to secure the site at St. John's-gardens, Millbank, on which a new hospital is to be built at a cost of £700,000. Two large donations lately received which have helped to bring the fund to its present total of nearly £107,000 are £10,000 voted by the Middlesex county council and £5000 from the James Gardiner trust. The other half of the sum needed to buy the site will, it is hoped, be obtained by selling the ground occupied by the present building.

Soho-square Hospital for Women

The 1410 in-patients treated last year were the lowest number since 1929, and consequently the average cost per patient increased considerably. The number of new out-patients has also fallen, but the attendances have increased owing to the opening of the new clinic for the special treatment of certain cases.

A Waiting-list at Belfast

On Dec. 31st, 1933, the waiting-list at the Royal Victoria Hospital, Belfast, numbered 1025. There were 6285 admissions, the highest on record, but the average stay of 21·9 days was the shortest yet recorded, being a reduction of 2·5 days compared with 1932. Last year the hospital spent £1590 upon motor accident patients, of which only £374 had been recovered. At the end of the year there were, however, still 127 claims outstanding. The daily average number of beds occupied was 400.

Hospital Treatment for the Middle Class

After long negotiations a scheme has been agreed to by the Hospital Service Association and the Hospital Staffs Association at Liverpool whereby hospital treatment is assured to people of the middle class. For a payment of 1s. per week, contributors with no dependents, whose annual income does not exceed £400, or with one dependent £500, or with more than one dependent £600, will be entitled to first-class hospital treatment, including necessary surgical and medical attention whilst an in-patient. Dependents of a person whose income comes within these limits also are entitled to benefit. A minimum membership of 10,000 is anticipated.

Royal Northern Hhe lines was of im

At the re une problem of dust in min Royal Northern Group of range of hospital sion were being l complement of be recent annual meeting of the any for the last two Hospitals it was stated that the with the casualty is 466, of which 43 have been the total, received years for lack of means. Last closed nor accident department, which is the Islington war year the id's pay- 17,475 patients, a large number of memorial that the cases. Patients, including those in them motor completed bed wing, paid a total of £54,346. the St. Dav the main nurses' home, begun last year, will It is hoped £139,000, to accommodate the 156 nurses speedily be co buildings building of the group. The debt who are in 0. of which £73,000 is on account now amounts to of the whole group; their cost of the land and has been £433,00

NOTES, COMMENTS, AND ABSTRACTS

THE MARYLEBONE RHEUMATISM CLINIC

THE fourth year of the British Red Cross Society's clinic for rheumatism at Peto-place, Marylebone-road, has shown the staff the kind of clinical material that may be expected at an out-patient department of this kind. According to the classification now approved by the visiting physicians the percentage of patients was as follows:—

Patients Showing Some Form of Rheumatism

	Group A. Articular.	*Group B.* Non-articular.
1. Infective—		
(*a*) Non-specific	15·5	11·4
(*b*) Specific	1·8	1·3
2. Traumatic	2·8	2·0
3. Degenerative—		
(*a*) Senile (osteo-arthritis) ..	17·0	0·3
(*b*) Climacteric	5·1	1·2
4. Metabolic—		
(*a*) Gout	2·2	0·3
(*b*) Rheumatoid	4·3	0·04
(*c*) Other Metabolic	2·8	2·3
5. Unclassified	2·1	17·3
	53·6	36·1
Group C.—Patients suffering from some sequel of rheumatic fever		2·3
Group D.—Patients suffering from non-rheumatic conditions		8·0

There has been little variation in the relative percentages of the main groups for the past three years. A large number of patients suffering from some manifestation of rheumatism had, in addition, some associated non-rheumatic condition (but are not included in Group D).

Any attempt to assess the gross results of treatment must, in the medical board's opinion, be accepted with a certain amount of reserve, since there are so many factors that modify interpretation and deduction. The stage of the disease at which the patient comes up for treatment, the type of the rheumatic manifestation, the economic factor, the nature of the patient's occupation, the ability of the patient to take full advantage of the resources available for treatment, the presence of any associated non-rheumatic disease, all tend to alter and detract from the value of any figures that may be quoted. Bearing all these facts in mind, the following figures represent the results of the investigation into the effect of treatment on the 957 men and 1615 women who were discharged from the clinic during 1933. Of these 196 men and 419 women did not complete their treatment; 43 men and 54 women were discharged on account of intercurrent disease. Of the remaining 718 men and 1142 women:—

—	Men.	Women.	Men and women.
	Per cent.		
Cured	26·0	13·2	18·3
Considerably improved ..	25·9	27·6	26·8
Definitely ,, ..	32·5	36·6	35·0
Slightly ,, ..	2·2	3·8	3·2
Unchanged	12·1	17·8	15·6
Worse	1·3	1·0	1·1

This year, as last, the percentage of men discharged as cured is almost double that of the women. The explanation given is that a larger proportion of men attending the clinic were suffering from some non-articular form of rheumatism, and that men, being usually the chief wage-earner of the family, were more likely to present themselves for treatment early, owing to the serious economic results of prolonged disability.

During the year the ten beds allocated for in-patient treatment to the clinic by the London County Council have been transferred from St. Charles' Hospital to St. Stephen's. The report emphasises the need for facilities to be provided for in-patient treatment under their supervision at a site near to the clinic, where any special or detailed investigations, as well as any form of physical or other type of treatment can be carried out that would be impracticable in an out-patient department. The lack of these facilities is proving a handicap to the work.

The need for continued research is being borne in mind. There are several clinical assistants whose time is now almost entirely taken up with routine examinations and investigations. Some grant of money would be required if new investigations are to be made, and the appointment of one or more full-time research workers would have to be considered. Directions of past and present work are these:—

An investigation of the vasomotor changes in rheumatoid arthritis.

The effect of vaccine treatment of rheumatism.

A comparison of the clinical results of treatment by autogenous, stock, and non-specific vaccines.

The value of acetylcholine injections in the treatment of rheumatism.

The assessment of the climatic factors in the rheumatic diseases.

An investigation of the types of arthritis occurring at the menopause.

The value of histamine ionisation in the treatment of rheumatism.

The treatment of arthritis by pelvic diathermy.

A comparison of the results obtained by different physical treatments.

Differential diagnosis of chronic arthritis affecting the hip-joint.

The value of the sedimentation-rate.

The use of gold salts in the treatment of arthritis.

Periodic demonstrations are given by members of the visiting staff, and regular courses of post-graduate lectures under the auspices of the Fellowship of Medicine. Lectures in medical hydrology have also been delivered to members of the Chartered Society. Each visiting physician has a senior as well as several junior clinical assistants; the appointment enables qualified practitioners anxious to gain experience of the physiotherapeutic and other methods employed in the treatment of rheumatism.

LEAD AND WATER

ALTHOUGH poisoning due to the use of lead pipes for conveying water has been recognised since Roman times it still finds occasional victims—as, for instance, in the Scottish outbreak reported in our columns last year.[1] It is, therefore, cause for satisfaction that the Water Pollution Research Board is devoting attention to this source of danger. A summary of existing knowledge of the subject has just been issued by the Board, apparently as a preliminary to research at the Chemical Research Laboratory, Teddington, and this summary,[2] which has been prepared by Mr. H. Ingleson, D.Phil., itself illustrates the need for investigation under precisely defined conditions.

On the physiological or pathological side it seems that people vary greatly in their susceptibility to lead poisoning and that the classical symptoms associated with industrial poisoning are not necessarily to be expected when the lead is taken in drinking water. At the outset Ingleson quotes Wynne, who thinks it possible that "rheumatic" cases which derive temporary benefit at watering-places and spas may be cases of undetected plumbism arising from small quantities of lead habitually ingested with water. Since the urine and fæces of "normal" subjects contain appreciable quantities of lead it is difficult to say when lead ingestion begins to be harmful. Various authorities give widely differing amounts of lead as conferring dangerous properties on water, for whilst Wright, Sappington, and Rantoul consider that as little as 0·3 part per million has caused poisoning, and most American workers fix this as a limit, Thresh, Beale, and Suckling would allow up to 0·5 part and A. Smith has found that 1·44 part is "not dangerous to some people." It may be observed that some drink very little water, and that lead tends to be removed from solution (or quasi-solution) in the process of preparing tea or coffee.

[2] Department of Scientific and Industrial Research, Water Pollution Research, Technical Paper No. 4, The Action of Water on Lead with special reference to the Supply of Drinking Water, Summary of Existing Knowledge. By H. Ingleson, M.A., D.Phil. London: H.M. Stationery Office. 1934. 2*s*.

Ingleson states that lead pipes are in use in Cordova which date from the Moorish occupation about A.D. 850 and other very old pipes are in use and have given rise to no toxic symptoms. It is usually stated that hard water attacks lead less than soft water, but though this seems in the main to be true, notable exceptions have been observed. It may be taken as certain that pure distilled water does not act on pure lead in the absence of oxygen. This was shown by Lambert and Cullis, who also found that whilst lead which had been in contact with water for 12 months was tarnished only slowly when oxygen was admitted, in some cases lead which had been in water for only a few days after it (the lead) had been distilled tarnished rapidly when oxygen was admitted. In fact the amount of attack seems to depend on the state of the lead or on the metals with which it is alloyed as well as on the impurities of the water.

NEW PREPARATIONS

Somnacetin (Dr. R. and Dr. O. Weil, Frankfort-on-Main. *Agent:* Francis O. Rudloph-Riddell, Sentinel House, Southampton-row, London, W.C.).—This is a hypnotic of the barbituric group concerning whose utility articles have appeared in the German press for several years. It is a Sodium-diethyl-barbitone-Phenacetin-Codeine combination, and the literature confirms what might be expected of it therapeutically. We note that several of the articles give warning of the risks that may be incurred in taking it, but there appears to be no such caution issued with the various preparations—ampoules, tablets, capsules, drops, and suppositories. These are put on the market in convenient form and neatly packed, and the preparation has behind it useful authority as hypnotic and sedative.

Menformon (Organon Laboratories, 1, Gordon-square, London, W.C.).—This œstrogenic hormone is put up in two forms, an oily solution where each 1 c.cm. contains 10,000 international units and a watery solution where each 1 c.cm. contains 1000 international units. The biological standardisation has been carried out in the laboratories of the company at Oss, Holland, by Prof. E. Laqueur, director of the department of pharmacology and therapeutics, Amsterdam. The aqueous solution is stated to be the strongest that can be made without precipitation and is easy to inject.

Births, Marriages, and Deaths

BIRTHS

Bailey.—On March 24th, at Bentinck-street, the wife of Dr. C. P. Bailey, The Chantry, Ingatestone, Essex, of a daughter.

Davidson.—On March 24th, the wife of A. Whyte Davidson, F.R.C.S.E., Christchurch, Hants, of a daughter.

Earlam.—On March 26th, the wife of Francis Earlam, M.D., Quendale, Mossley Hill, Liverpool 18, of a son.

Power.—On March 26th, at Hereford, the wife of R. Wood Power, F.R.C.S.I., of a son.

MARRIAGES

Abrahams—Lesser.—On March 27th, Sidney Abrahams, M.D., of Grove Green-road, Leytonstone, to Marion Hilary, [illegible] Mrs. Albert Lesser, of Brondes-[illegible] N.W.

[illegible] Church, Wigan, on April 2nd, [illegible] Marjorie Birch, M.B., Ch.B., only daughter of Mr. and Mrs. A. J. Birch, of Gidlow-lane, Wigan.

DEATHS

Fernie.—On March 30th, at Stone, Staffordshire, John Firth Fernie, M.R.C.S., L.R.C.P., aged 61 years.

Nixon.—On March 24th, at Plympton House, Plympton, John Clarke Nixon, M.B., aged 63 years.

Park.—On March 31st, George Williamson Park, M.B., C.M., B.Sc., of Abbotsford-crescent, Edinburgh, late of the Medical Department, Edinburgh Town Council.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Appointments

Radford, M., M.D., B.S. Lond., has been appointed Medical Officer of Health for St. Pancras.

City of London Maternity Hospital: **Moon, A. A.**, M.B. Syd., Senior Resident Medical Officer; **Gilbert, B.**, M.B., B.S. Lond., Junior Resident Medical Officer.

Medical Referees under the Workmen's Compensation Act: **Batt, B. E. A.**, M.B., B.Ch. Oxf. (Circuit 33, Bury St. Edmunds, &c.); **Drinkwater, S. W.**, M.B., Ch.B. Manch. (Circuit 23, Atherstone, &c.).

Vacancies

Lord Mayor Treloar Cripples' Hospital and College, Alton, Hants.—Asst. Res. M.O. £150–£200.
Manchester, St. Mary's Hospitals.—Three H.S.'s to Spec. Depts. Each at rate of £50.
Margate, Royal Sea-Bathing Hospital.—Res. Asst. Med. Supt. £500.
Merthyr Tydfil Education [illegible] £500.
[illegible]).
[illegible] Ophth. Surg. Also Hon. Asst. Radiologist.
Nelson Hospital, Merton, S.W.—Res. H.S. At rate of £100.
Nottingham General Hospital.—H.P. At rate of £150.
Preston County Borough.—Asst. School M.O. £500.
Preston, County Mental Hospital, Whittingham.—Deputy Med. Supt. £750.
Princess Elizabeth of York Hospital for Children, Shadwell, E.—H.P. and Cas. O. Each at rate of £125.
Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.—Hon. Ear, Throat, and Nose Surgeon.
Reading, Royal Berkshire Hospital.—H.P., H.S., and Cas. O. Each at rate of £150.
Rochdale Infirmary and Dispensary.—Jun. H.S. £200.
Rotherham Hospital.—Cas. H.S. £150.
Royal College of Surgeons of England.—Examiners.
Royal Masonic Hospital, Ravenscourt-park, W.—Res. Surg. O. At rate of £250.
St. Thomas's Hospital, S.E.—Physician.
Samaritan Free Hospital for Women, Marylebone-road, N.W.—H.S. At rate of £100.
Smethwick County Borough.—Sen. Asst. M.O.H. £750.
Southampton, Royal South Hants and Southampton Hospital.—Hon. Clin. Asst. to Ear, Nose, and Throat Dept.
Southend-on-Sea General Hospital.—Cas. O. At rate of £100.
South London Hospital for Women, Clapham Common, S.W.—H.P. At rate of £100.
Southport General Infirmary.—Jun. H.S. £150.
Stafford, Staffordshire General Infirmary.—H.P. At rate of £150.
Swansea General and Eye Hospital.—H.P. At rate of £150.
West End Hospital for Nervous Diseases, Gloucester Gate, Regent's Park, N.W.—H.P. At rate of £150.
Western Ophthalmic Hospital, Marylebone-road, N.W.—Sen. and Jun. Res. H.S.'s. At rate of £150 and £100 respectively.
Woodside Hospital, Woodside Avenue, Muswell Hill, N.—H.P. £100.

Donations and Bequests.—Greenock Royal Infirmary and Larkfield Hospital will benefit by a legacy of £1000 which has been left by ex-Bailie John Alston, at one time chairman of directors, for the purpose of endowing a bed in memory of his sister, Miss Janet Hill Alston.

ADDRESSES AND ORIGINAL ARTICLES

THE MEDICAL CURRICULUM AND MEDICAL EDUCATION

BY CHARLES A. PANNETT, M.D.Lond., F.R.C.S.Eng.

PROFESSOR OF SURGERY, UNIVERSITY OF LONDON; SURGEON TO ST. MARY'S HOSPITAL

FROM time to time above the undergraduate murmurings of discontent at the appalling and discouraging prospect of the present day medical curriculum is heard the voice of a dean or teacher of a medical school, commiserating with the student, criticising and condemning, though not with perhaps the same freedom of expression, what every reasonable man must regard as an educational structure which has grown unwieldy and cumbersome in its size and distorted in its scope. There is a movement for reform not only in this country but in almost every land abroad. Much has been written of late and many true things said about the defects of the present system. What most writers are agreed upon is the necessity for some simplification and the need to unburden the curriculum of things of doubtful value. The real difficulty is in knowing what things to withdraw; in fact, to assess the educative value of its different parts.

THE EARLIER STUDIES

There is an underlying current of revolt against the preliminary subjects chemistry, physics, and biology being taught by specialists who have no medical interest, against anatomy and physiology being taught with no reference to disease and a desire to introduce these teachers into the hospital wards and their students to clinical problems at a very early stage of their career. There is particularly a tendency to advocate the instilling of knowledge which has a practical bearing on the work of the later years. Let us cut out botany, says one man; it has little relation to clinical medicine; and of what use is it to learn the anatomy of a dogfish asks another? The intricacies of human anatomy will soon be forgotten and the minutiæ of physiology are of doubtful value.

THE LATER CLINICAL YEARS

With one accord there is a demand to prolong the period during which the student is in clinical contact with the patient. But, say the critics, cease to burden his mind with innumerable facts, teach him principles, train him to think. Remember that the bulk of all students will become general practitioners. Equip them always with this aim in view. Cease to emphasise and in some cases omit instruction in the rarer diseases. Concentrate upon the common problems of everyday practice.

THE OBJECT OF MEDICAL EDUCATION

It is well indeed for us to keep in the forefront of our minds the object of the training of the medical student. It is first and foremost the production of a doctor in whose hands the general public may implicitly entrust the care of their bodily ills. Now such a man must above all have a sound knowledge of general medicine and surgery, but he must have in addition a brain trained to deal intelligently with other than medical problems of life, he must possess that priceless quality common sense. We must also remember that some, and indeed perhaps an unadvantageous increasing number of students, will want to specialise. The path to them must remain open.

AN ANALYSIS OF THE DEMANDS

Amongst all the voluminous criticism of the medical curriculum there is a repeated reversion to this ideal of the production of the sound general practitioner, the practical man, the man of common sense; and hints, rather vague, by most of the critics, that some simple modification of the syllabus or methods will achieve this end. There is a reiteration of the advice to inculcate principles, eliminate details, abolish the memorising of innumerable facts, to train the man to think. There is a rather significant absence of instruction as to the methods by which these laudable ambitions may be attained. There are several misconceptions involved in this view of medical education. There are the quite unwarranted assumptions that in general the clinical phenomena of disease conform to established laws and principles, that the facts of disease are of secondary importance, that it is actually possible to teach men to think. When we test the truth of the first assumption we find the simple principles, for example, that the obstruction of the duct of any gland will cause dilatation of the channels behind the hindrance and predispose to infection, are singularly few in number. We find that when we try to make the phenomena of immunity conform to some law as did Ehrlich in his famous side-chain theory, that the exceptions are so numerous and the departures from the expected necessitate such complicated modifications of the hypothesis that it becomes in fact a lamentable failure. Or again, take the enunciation that hyperæmia leads to decalcification of bone. The upholders of this are forced to resort to the most curious explanations to make the facts conform to principles, and we are forced to admit that the science of medicine has not yet reached that stage in which many simplifying laws are established. Neither can we, if we are to be of any use in medicine, dispense with hundreds of isolated and unrelated facts. No intellectual process could lead a man to the deduction that the commonest site of a rodent ulcer is beside the nose, a very useful fact for diagnosis, any more than it could reveal to him that a robin has a red breast. The science of medicine has not yet passed beyond the stage of the collection of multiple facts. Their correlation is yet in a very rudimentary stage. The acquisition of a multitude of facts is unfortunately for the indolent an indispensable qualification for a very mediocre practitioner.

Then there is this question of teaching a man to think. No student can be taught to think. He may have pointed out to him the similarities or differences of things, the sequences of events with the hope that he will similarly correlate other facts in nature that he may observe. But this is indeed the common procedure in all education and is in no way peculiar to medicine. Lastly, without troubling ourselves how it is to be acquired, we may helpfully inquire into the nature of that quality called common sense. This is very simply stated. It is nothing more than the knowledge of how inanimate matter or human beings react to change in their environment. It is really an intimate knowledge of natural phenomena. That iron is hard, wool soft, that a match will not support the weight of a ton, that an electric current in the neighbourhood of a magnet will cause the latter to deviate, when applied to the problems of everyday life are all examples of the use of common sense, so is the application of the much more difficultly acquired and subtle knowledge that one man will be courageous in the face of danger, another a craven, a third trustworthy, a fourth self-reliant. This is usually called a knowledge of human nature.

FUNDAMENTAL CONSIDERATIONS IN CURRICULUM REFORM

It is such simple but supremely important considerations, so briefly set out above, that must dominate any attempt to reform the medical curriculum. If above all things we want our doctors to think clearly about the manifold problems of general practice we can scarcely lay too much stress upon a preliminary education which comprises some exact branch of knowledge. It does not really matter whether this is the practice of mathematics, the writing of Latin prose, or the accurate experimentation of the physicist, provided the student advances sufficiently into his subject to have his intellectual processes drilled into exact methods. It is this intellectual attitude rather than the knowledge gained which will be of priceless value to him for the remainder of his life. This is the argument above all others against making the preliminary and intermediate subjects take on too much an applied character, against the abolition of professional chemists, anatomists, or physiologists as some seem actually to desire. Taking a long view it would be unwise to curtail the preliminary sciences, chemistry, physics, and biology. Rather would more physics and chemistry appear to be of more ultimate value to the future practitioner from the utilitarian point of view. Neither does it seem profitable to reduce the time spent upon anatomy, histology, and physiology. These are of such importance as the basis of clinical medicine that groundwork in them can scarcely be too thorough. I do not believe that the modern anatomist is out of touch with surgical or medical needs. In this and other preclinical subjects the syllabus can best be left to the judgment of a select committee of the several experts. The educational value of their recommendations is likely to be much greater than any scheme evolved by clinical teachers.

The intellectual preparation of the student during his preclinical years is likely to be jeopardised by his early introduction to clinical methods frequently so lacking in exactitude, and the incalculable advantage of a training in pure science during his most impressionable years might be lost. On the whole I do not think anything would be gained by the early introduction of the student to clinical work.

THE CLINICAL PERIOD

But having been prepared by this seemingly long training in the preliminary subjects, having acquired, it is hoped, right intellectual habits, the more clinical contacts the student can acquire the better. If his former training has been really good the less he is worried by lectures the better. There is one exception, he should attend a long and comprehensive course of pathology. The system of forcing him to devote his first three months exclusively to this subject has much in its favour. More time should be given to general medicine and surgery than to the specialties. He should be free to roam rather than forced into specialised channels. Let him acquire as many facts as he can. It will never again be as easy to him as in the early twenties.

THE STUDY OF COMMON DISEASES AND CONSIDERATION OF THE RARE

There is much to be said for stressing the phenomena of the common diseases met with in general practice, but it does not appear to me that general practitioners' services need be enlisted for this purpose. The phenomena of such diseases are well known, but many of them are not suitable from an educational point of view as examples of infectious or other illness owing to the defects of knowledge of their ætiology, prevention, and treatment. We have only to mention the common cold, fibrositis, influenza, to realise the truth of this statement. Perhaps a few clinical teachers in their enthusiasm for some special study lay too much stress upon rarer forms of disease, but let us not forget that the examples upon which they teach actually come from general practice, and if a student is to know anything about them he must learn them at hospital, for the opportunity may seldom present itself again. Similar considerations apply to instruction in methods and surgical operations which the doctor may never have to practise himself. Surely it is the duty of the clinical teacher to present a vista of medicine to its very boundaries. The practitioner must know, in the interests of his patients, not only that rare diseases exist, but where to turn up the knowledge of such diseases, and he must know the therapeutic possibilities that science and skill have placed in our hands. We must not take a too utilitarian narrow view of the needs of the ordinary general practitioner. It is not waste of time for a dresser to hold a retractor during a long complicated operation provided he be observant and allowed to handle diseased tissue in life. With the active circulation in being many abdominal conditions present a very different picture from that in the post-mortem room. Moreover, it is a nearer picture to that he must conjure up in treating the living man, for in the dead house the lesion has too frequently reached a stage incompatible with life. It is as essential for a dresser to handle an actual cancer in a living man as for a clerk to dissect a similar lesion in a corpse.

ATTAINMENT OF COMMON SENSE AND THE KNOWLEDGE OF HUMAN NATURE

Neither of these branches of knowledge can be taught as such but both can be acquired. From the considerations of the nature of common sense it can be seen how helpful it is to engage in some occupation which necessitates the attainment of some manual skill. It is the duty of those who have the welfare of medical students and of their future patients at heart actively to encourage the pursuit of some hobby, particularly one needing work with the hands. There must be a technique and one not too simple to acquire. The knowledge of the reaction of inanimate matter to change, the essence of common sense, can be gained in no quicker, more efficient, or pleasanter way. Every student with any surgical aspirations should at least have one or other hobby, artistic, mechanical, musical, but it must be executive. On the other hand, the social activities of a medical school should be carefully fostered—the games and other communal occupations. It is an error to consider that they have no part in medical education. The human contacts that they bring are of inestimable value. We cannot teach the knowledge of human nature, neither do we suggest in any other calling in life that instruction in it should be given. It is not possible to do so. We teach to engineering students the facts of engineering, to law students law, so we can only teach to medical students the facts of disease. But as it is more essential for them to acquire knowledge of the psychology of the man in the street, we must induce them to do so in the only possible way by encouraging the social side of the medical school. The hermit student may become learned but he will never become a good general practitioner.

THE FINAL WORD

It is a foregone conclusion that some reform of the medical curriculum is long overdue. There are many suggestions, too many with a utilitarian objective, which would defeat the aims of a true education and only lead to the production of an inferior type of practitioner. The considerations I have outlined aim at giving a man a proper intellectual outlook. Applied science will not always accomplish this. The problems of practice are so manifold, so varied, so unexpected that the utmost we can hope to do in preparation for it is to equip a man with a sufficiency of the facts of disease, but above all to provide him with those qualities of the mind which will enable him to attack them in an intelligent and effective fashion. If we keep these main aspirations in view it will surely not be impossible for the wise leaders of the different departments of medicine to select the essentials and eliminate the useless from an edifice which has become top heavy, overloaded, and disproportionately developed, and an unfair burden to the modern medical student whose quality has surely never in history been surpassed.

THE BLOOD-BRAIN BARRIER IN INFECTIOUS DISEASES

ITS PERMEABILITY TO TOXINS IN RELATION TO THEIR ELECTRICAL CHARGES

BY ULRICH FRIEDEMANN, M.D. Berlin
LATE DIRECTOR OF THE INFECTIOUS DISEASES DEPARTMENT, RUDOLF VIRCHOW HOSPITAL, BERLIN; AND

A. ELKELES, M.D. Berlin.
LATE CHIEF ASSISTANT OF THE DEPARTMENT

(Concluded from p. 724)

5. The Electrical Charge of Toxins in Connexion with their Ability to Pass the B.B.B.

The problem which now presents itself is, why some toxins pass the blood-brain barrier and others do not.

At the beginning of our investigations this problem had been formulated only for very few substances. The well-known experiments on narcosis, on vital staining, and our previous studies on the B.B.B. suggest that the passage of chemical substances through the B.B.B. is favoured mainly by the possession of any one of three properties—viz., lipoid solubility, a high degree of diffusibility, and a basic character.

Lipoid solubility must be regarded as the quality to which narcotics owe their ability to pass the B.B.B. But lipoid solubility is not an outstanding quality of toxins, and there is no reason to suppose that differences in this quality explain the sharp differences between the two groups. Indeed, it is not certain that toxins are lipoid soluble at all. Some have thought that because certain toxins are absorbed by brain tissue they must be lipoid soluble, but other workers have argued that proteins and not lipoids, are responsible for the absorption. But whichever contention is right, we know that tetanus toxin is absorbed by brain tissue but cannot pass the blood-brain barrier.

That *diffusibility* facilitates permeation through the B.B.B. has been shown by Spatz [41] for acid dyes. Among basic dyes diffusibility seems to be of no significance. This factor can, however, be neglected when dealing with toxins. For all toxins are colloids and differ very little in their degree of dispersion.

Friedemann and Elkeles pointed out that among dyes and drugs *basic and acid character* have a dominant part in determining whether a substance shall or shall not pass the blood-brain barrier. It was already known to Ehrlich that nearly all basic dyes, with the exception of the triphenyl-methane group, when injected into the blood stream stain the brain. Some other basic dyes were found to do so by Wesselkin, Friedemann and Elkeles, and H. Schmid. Obviously these dyes pass the B.B.B. On the other hand, Ehrlich [43] supposed that acid dyes, with the exception of alizarin † and aurantia, do not stain the brain under the same conditions. According to Spatz that is not quite true of highly diffusible dyes. But, at any rate, they stain the brain very slightly, as compared with basic dyes, and the cerebrospinal fluid contains more of the dyes than the brain. Acid colloidal dyes leave the brain completely uncoloured when injected intravenously, but they do stain the brain definitely when the B.B.B. is circumvented or damaged. This was shown by Goldmann and Doinikow [43] for trypan-blue, isamin-blue, pyrrhol-blue, by Rosenbaum,[44] Stern, Kassil, and Lockschina [45] for Congo red. Inability of these dyes to stain the brain when injected into the blood stream is therefore exclusively due to their inability to pass the B.B.B.

Thus, in view of what is already known, it seems rational to suppose that amongst toxins, as amongst dyes, basic character may be found to favour passage through the B.B.B. and acid character to hinder. To arrive at the facts by direct methods is, however, difficult, as the chemical constitution of toxins is quite unknown. Basic and acid character is, however, well known to be associated with positive and negative electrical charges, which can be determined by cataphoresis. Cataphoresis experiments were therefore carried out on diphtheria-, tetanus-, botulinus-, and lamb-dysentery toxin and on cobra venom, in order to determine whether, according to their electrical charges, toxins fall into the same groups as they do according to their ability to pass the B.B.B.

The information we could gather from the literature on the cataphoresis of toxins is scanty. As far as we know, only ricin and abrin have been investigated (Landsteiner and Pauli [46]). They proved to be amphoteric colloids, their electrical charge being dependant on the pH of the solution. Bearing this fact in mind, our toxins were investigated in solutions of varying pH. Since, however, for our problem the electrical charge at the pH of the blood was of outstanding importance, only solutions of pH equal to 6·2, pH=7·4, pH=8·2 were used. They were prepared with phosphate buffers. Cobra venom, in addition to that, was investigated in a n/100 NaOH solution. The electrical current was passed for 40 minutes. Convection currents were avoided by adding 1–5 per cent. glucose to the solutions of toxins under investigation, in order to increase their specific gravities.

The toxicity of anode and cathode fluids was tested on a large series of animals; no detailed protocols are given. Before, however, proceeding to the results of these experiments a few points concerning the technique should be mentioned here.

---

† Alizarin-blue too seems to be an exception to the rule. Ehrlich considered it to be an amphoteric dye and ascribed its ability to stain the brain vitally to its basic group. We found that in the electrical current it behaved like an acid dye; even in a n/10 HCl solution it passed to the anode. Keeping in mind the fact that in the blood it is present in colloidal form (Ehrlich), we can as yet give no satisfactory explanation for its ability to pass the B.B.B.

In experiments with diphtheria toxin the tests of anode and cathode fluids were made by subcutaneous injections into guinea-pigs of a standard weight of 250 g. In experiments with botulinus toxin the tests were made by intraperitoneal injections into mice. In experiments with tetanus toxin the potency tests were made by intramuscular injections in mice. The exceptionally high diffusibility of this toxin caused much trouble. Until we reduced the strength of our solutions to a suitable level toxin appeared in both arms of our apparatus, even when no current whatever had been passed. In the experiments with lamb-dysentery toxin our first attempts to test anode and cathode fluids were made by the intravenous injection of mice. These animals are very sensitive to the toxin, but we found them quite unsuitable for our purpose. Control experiments showed that intravenously injected cathode fluid was toxic to mice, even when plain saline had been substituted for the usual toxin solution. We failed to find the explanation of this toxicity, but the matter is of no importance for our present purpose. These difficulties could be avoided by using rabbits, into which the anode and cathode fluids were injected intravenously.

The results obtained in our cataphoresis experiments are summarised in Table V., in which "A" means that the toxin passed to the anode, "C" means that it passed to the cathode, and "O" that there was no change.

TABLE V

Toxins	pH 8·2	pH 7·4	pH 6·2
Diphtheria	A	A	A
Botulinus	A	A	A
Tetanus	A	A	A and C
Lamb dysentery	A	O	C
Cobra	C	C	C

Perhaps the first point to be discussed is the information our experiments give concerning the iso-electric point in the toxins investigated.

The iso-electric point was approximately determined for lamb-dysentery toxin at pH=7·4, and for cobra venom at a pH between 8·2 and the pH of a n/100 NaOH solution. These toxins, therefore, are amphoteric colloids. Our experiments give no information on the iso-electric point in diphtheria, tetanus, and botulinus toxins. All we can say is that apparently the iso-electric point was not reached within the range of phosphate buffers. But in the solutions of higher acidity these toxins are rather unstable. We shall see from the Table that at pH=6·2 tetanus toxin was found in both arms of the apparatus. We would not, however, assert with any certainty that at pH=6·2 the iso-electric point of tetanus toxin was reached. We have already remarked on the exceptionally high diffusibility of tetanus toxin, and there is the possibility that at pH=6·2 the diffusibility of the toxin is still further enhanced.

But for us the main interest in the tabulated results of the cataphoresis experiments is that they show clearly that, at the pH of the blood, there is a striking correlation between the electrical charge and the ability to pass the blood-brain barrier. Tetanus, diphtheria, and botulinus toxin, the three toxins of our series which are definitely known not to pass the B.B.B., were found to carry a negative charge; whilst of the two toxins definitely known to pass the B.B.B. one, the toxin of cobra venom, was found to carry a positive charge, and the other, the toxin of lamb dysentery, was found to be neutral.

Our results show that the behaviour of toxins fairly agrees with that of dyes and drugs, and confirm our opinion that acid and basic character or electrical charges are, in their case also, the dominant factors which control permeation through the B.B.B. It is impossible as yet to explain these results theoretically with any degree of certainty, as the more intimate mechanism of the B.B.B. is completely unknown. Explanations on the basis of Donnan equilibria or electrical potentials of capillary walls would be merely speculative.

It is, however, noteworthy that the electrical charges of toxins seem to be associated with another quality. The three toxins carrying a negative electrical charge fall into the group of toxins characterised by a long incubation period. Lamb-dysentery toxin and cobra venom, carrying either no charge at all or a positive one at the pH of the blood, act rapidly, without any significant incubation period. Obviously the rapidity of the action of these toxins is due to their facility to pass living membranes, and this facility depends upon their positive charges, or at least on the absence of a negative electrical charge. Here again an analogy to dyes may be stated. It is well known that basic dyes are very toxic, and, when given in sufficient amount, kill animals instantly, whereas acid dyes can be given in large amounts without toxic effects (Krebs and Wittgensteiner [47]).

The same inter-relations between the electrical charge, ability to pass the B.B.B., and readiness of passing from blood to tissues seem to hold for some drugs. Germanin, for instance, is known to exhibit no tendency to pass from blood to tissues, and therefore remains in the blood for weeks. We found it entirely unable to pass the B.B.B. Although almost innocuous when injected intravenously, it proved to be extremely toxic by the intrathecal route. Further, we found that Germanin carries a negative charge.

Discussion

The most important outcome of our studies, as we believe, is the demonstration that the blood-brain barrier plays an important and a hitherto overlooked part in the pathogenesis of infectious diseases. From a reconsideration of the literature and from experiments of our own, we have arrived at the conclusion that this barrier is impermeable to some toxins—e.g., diphtheria and botulinus toxin—which were hitherto generally supposed to owe their lethal effects to their actions on the brain. Further, it could be shown that toxins differ amongst themselves in their ability to pass the B.B.B. From this point of view toxins fall into two distinct groups, one of which, containing lamb-dysentery toxin and cobra venom, does pass the B.B.B., whereas the other, containing tetanus, diphtheria, and botulinus toxins, does not pass it. The toxins fall into the same groups when arranged according to their electrical charges. Diphtheria, tetanus, and botulinus toxin carry a negative charge at the pH of the blood, lamb-dysentery toxin is neutral, and cobra venom carries a positive charge. It would thus appear that a negative charge inhibits permeation through the B.B.B.

Our results apparently also have a bearing on the problem of the incubation period of toxins which hitherto has remained mysterious, except the case of the tetanus toxin. Diphtheria, tetanus, and botulinus toxins, which carry a negative charge and do not pass the B.B.B., follow the general rule that toxins exhibit a long incubation period. Lamb-dysentery toxin and cobra venom, which carry no negative charge, and pass the B.B.B., act rapidly, without any significant incubation period. From this and, as stated above, from experiments with dyes and drugs, we infer that the length of the incubation period is in some way connected with the readiness with which toxins pass from the blood to the tissues, and that this latter property depends on their electrical charge.

We have thus reached a point at which biological effects of toxins can be correlated to some physico-chemical properties which can be determined experimentally. Hitherto these effects could only be explained by hypothetical specific affinities of toxins for certain tissues according to Ehrlich's theory. We do not deny specific affinities between toxins and tissues. But electrical charge, determining the permeation through the B.B.B. and the length of the incubation period, is the predominant factor. There is little doubt that our results have also a bearing on drugs. They may become helpful in the synthetical production of drugs expected to pass the B.B.B., and therefore in chemotherapy.

The fact established by our studies that diphtheria toxin does not act on the brain involves a considerable change in our conceptions on the pathogenesis of this disease. It is reflected in a series of our own clinical, histological, and electrocardiographic researches, which were carried out together with our former colleagues, Profs. Anders and Brandenburg, at the Rudolph Virchow Krankenhaus, Berlin. A short review of these studies has been given in a lecture in the "Verein für innere Medicin," Berlin, in May, 1932.[48] A more complete account of the pathogenesis of diphtheria will be given by one of us in the "Handbuch der inneren Medicin," v. Bergmann and Staehelin (in press). In this paper only the main points are dealt with.

The action of diphtheria toxin was hitherto supposed to be mainly localised in the brain and in the heart muscle. We have now found that the brain is not involved in diphtheria. Vasomotor collapse, in our opinion, is due to the action of diphtheria toxin on the vascular system and its peripheral nerves. This opinion fairly falls in with the results of Harding,[49] Bricker,[50] Molinelli,[51] and Myers[52] obtained with other methods. The way is now open for a more intimate investigation of the mechanism of toxic action on cells, and we suppose that this way may lead to new and fundamental conceptions.

Moreover, the pathological changes of the vascular system have now become the central problem in the pathogenesis of diphtheria. It has been shown that the toxic action on the vascular system, merely functional in the first stages of the disease, results in definite histological lesions, cellular infiltration and hæmorrhage in the early stages, and widespread destruction of the vascular system in the final phase. These changes have been described before but with the exception of Bricker[50] and Molinelli[51] they have not been connected with the problem of pathogenesis. The consecutive stages in the development of vascular lesions, we found, correspond to characteristic clinical symptoms and electrocardiographic findings. The various features and stages of the disease could be brought into a system on the basis of their pathogenesis. Heart failure was demonstrated to be due, to a certain extent at least, to lesions of the coronary vessels. This has been clearly demonstrated by us for heart-block.

Our treatment of diphtheria has been profoundly influenced by our investigations. The intrathecal application of antitoxin recommended by Bingel[53] and Speranski on order to protect brain centres was discarded as useless (Friedemann, Lukas, and Schmerel).[54]

The administration of drugs expected to increase the irritability of the vasomotor centre was abandoned after we had become aware that this centre is not involved in diphtheria. In fact, we never saw any effect of this treatment. On the contrary we found that the application of hot baths is very helpful in the conditions produced by vasomotor collapse in diphtheria. The method has been described in a previous communication.[48] The effects of this treatment are striking even in the most severe cases, and not to be compared with those of drugs. Symptoms are improved at once and remain so for hours. The efficiency of this therapy, in contrast with the complete futility of drugs, strongly confirms our conception of the peripheral origin of vasomotor collapse in diphtheria. It is suggestive that the same beneficial effect of heat has been observed experimentally by Cramer and Gye[55] in reducing the action of the toxin of *B. welchii*, which resembles that of diphtheria toxin in producing vasomotor collapse.

6. Summary and Conclusions

1. The blood-brain barrier is localised in the walls of the cerebral capillaries. The permeability of the blood-brain barrier coincides with that of the cerebral capillaries.

2. The methods for testing the permeability of the blood-brain barrier are discussed. In our own experiments with toxins four methods were used; (*a*) artificial perfusion of the brain; (*b*) auxoneurotropic effect; (*c*) comparative determination of the lethal dose of the toxin by the intravenous and the intrathecal route; and (*d*) identification of the toxin in the brain after intravenous injection.

3. As a result of a critical re-examination of the literature, and of our own experiments, we have arrived at the conclusion that the blood-brain barrier is permeable to cobra venom and lamb-dysentery toxin, and impermeable to diphtheria, botulinus, and tetanus toxins. The property of the toxins of vibrion Nasik and vibrion El-Tor are not sufficiently known.

4. Amongst the toxins investigated the ability to pass the blood-brain barrier is correlated to electrical charge. Diphtheria, tetanus, and botulinus toxins which do not pass the blood-brain barrier carry a negative charge at the pH of the blood. Of the two toxins which pass the blood-brain barrier, lamb-dysentery toxin is neutral and cobra toxin carries a positive charge at the pH of the blood.

5. It is suggested by our experiments that the electrical charge of toxins has a bearing on the problem of the incubation period. The two toxins which are either neutral or carry a positive charge have no incubation period.

6. The importance of these results for the pathogenesis of infectious diseases is discussed in the case of diphtheria.

The greater number of the experiments described in this paper were carried out in the Rudolf Virchow Krankenhaus, Berlin. In some of these experiments we were kindly assisted by Dr. Edith Bülbring. The hospitality extended to us by the Medical Research Council enabled us to complete the work at the Farm Laboratories, Mill Hill. We wish to express our thanks to Dr. W. E. Gye and Dr. W. J. Purdy for helping us to prepare the paper for publication, and to the Notgemeinschaft der Deutschen Wissenschaft for financial support.

ANEURYSM OF THE INNOMINATE ARTERY:

A TWENTY-THREE YEARS' HISTORY

BY CHARLES MILLER, M.D. Camb., F.R.C.P. Lond.
CONSULTING PHYSICIAN TO THE LONDON HOSPITAL

ROBERT DOLBEY, M.S. Lond., F.R.C.S. Eng.
LATE PROFESSOR OF CLINICAL SURGERY IN THE KASR-EL-AINI HOSPITAL, CAIRO; AND

SIR CHARLES BALLANCE, M.S. Lond., F.R.C.S. Eng.
CONSULTING SURGEON TO ST. THOMAS'S HOSPITAL

THE history is here recorded of an aneurysm of the innominate artery through a period of 23 years, during which the innominate artery was ligated and quinine urethane hydrochloride was injected with the object of preventing the aneurysm from rupturing through the skin of the neck.

Case Record

The patient, X, died in October, 1933, aged 63 years. He contracted syphilis in 1888 at the age of 17 years in Africa.

He was treated by ointment and pills. The treatment lasted about three weeks. A secondary rash was present for about two weeks. It is not clear why treatment was discontinued, but the doctor appears to have taken little interest in the case. From 1888 to 1910 the patient was perfectly fit and well. In 1910 he was engaged on a Canadian farm in heavy physical labour involving his arms in particular. This was followed by distress in breathing, high chest pain, and some pain in the back. Complete rest for a time relieved all the symptoms.

In 1911 the patient consulted one of us (R. D.) in Vancouver. There were definite signs of innominate aneurysm. The tumour extended above the inner half of the right clavicle and the pulsation was expansile.

Rest in bed for six weeks and five intravenous injections of salvarsan gave relief to the symptoms, and the physical signs were much diminished.

In 1912 X came to England and consulted one of us (C. M.). The Wassermann reaction was positive. Four injections of 606 were given, and early in 1913 three injections of 914. Mercury in the form of Hutchinson's pill was given for 18 months. The Wassermann reaction became negative after the administration of mercury but was positive after the injections of salvarsan. On March 11th, 1913, the X ray report was "an aneurysmal tumour of the innominate—very definite—with hardly any pulsation—slight dilatation of descending aorta." In April, 1913, he reported as feeling very fit, except for an occasional pain in the right arm. Some large veins were visible in the right infraclavicular region but otherwise there was apparently nothing abnormal. The supraclavicular pulsation had disappeared. He obtained a post under a public authority and successfully passed a medical examination before taking up his duties.

During 1914–18 the patient was engaged in strenuous war service in the North Sea. He had no leave and was perfectly fit and well, except that he was for a short time in Rosyth Hospital with bronchitis. In March, 1919, he complained of pain in the right arm and was admitted to hospital. An X ray examination was made: "On screen examination the aorta is seen to pulsate while the tumour does not pulsate. It has the usual well-defined outline suggestive of gumma in the superior mediastinum." The left brachial blood pressure was noted to be higher than the right. Later in 1919 he returned to Canada and resumed hard physical labour once more. The symptoms returned. High chest pain radiating to the right side of the neck and distress upon exertion were noted. He returned to England to be under the care of C. M. During 1922 and 1923 the Wassermann reaction was positive and antisyphilitic treatment with rest was resumed. The condition on this occasion did not become quiescent. The aneurysm increased in size in the neck and some dysphagia was complained of. There was displacement of the trachea to the left and a pulsating tumour above the right clavicle.

In 1925 the patient was admitted to St. Thomas's Home and came under the care of one of us (C. B.). At this time the aneurysm extended high up on the right side of the neck and there were prominent local bulges of the aneurysmal sac in the upper part of the anterior triangle and in the lower half of the posterior triangle. The upper border of the right clavicle was obscured by the fullness caused by the aneurysm in the lower part of the neck. Expansile pulsation could be felt from the median line in front to the trapezius muscle behind. Tracings of the temporal and radial arteries showed that the pulse in the arteries of the right side was smaller than the pulse in those of the left side, clearly demonstrating that the aneurysm was not aortic. The pupils were equal and there was neither dysphagia nor difficulty in breathing. Careful X ray studies were made especially with the radiographic screen:—

1. The arch of the aorta and the heart appeared normal.
2. The aneurysmal tumour involved the distal third or half of the innominate artery and its two branches at the bifurcation.
3. The proximal half or two-thirds of the innominate artery appeared not to be involved in the aneurysmal tumour. It was thought, however, that the artery was slightly wider than normal—that it was slightly dilated. The discovery that the proximal part of the artery was not involved in the aneurysm raised the question of operative interference.[1]

The problem of ligation of the innominate artery on the proximal side of the aneurysm was beset with difficulties. The long history of the aneurysmal tumour and of the syphilitic infection made it nearly certain that the tumour and the proximal part of the innominate artery would be found firmly fixed to the surrounding tissues. Further, the slight enlargement of the proximal part of the artery made it probable that the wall of the artery was thickened and more rigid than the normal arterial wall. Under such circumstances it might not be possible to close the lumen of the artery by means of a ligature.

These facts brought under consideration the possible value of a clamp.

Halsted had successfully occluded the thoracic and abdominal aorta in dogs by means of an aluminium clamp.

---

He had also used this method in man.[2] The problem in the dog with healthy arteries and without adhesions to surrounding tissues was different from the one presented by the patient. The first clamp[3] designed was made from a walrus tusk presented for the purpose by the patient, but it was found to be too small, so a second ivory clamp was made from an elephant tusk. The clamp worked well in the post-mortem room. When the clamp was closed, an interval of 3 mm. was left between the blades. Allowing for the thickness of the arterial wall being 1 mm. there would be left an interval of 1 mm. between the intimæ of opposite sides. It was thought probable that the arterial wall was thicker than 1 mm. Even if the lumen of the artery was not completely closed by the clamp it was probable that the multiplication of the cells of the tunica intima would soon occlude the artery. Besides, it was not known how thick the wall of the innominate artery was, and it was no part of the operation plan to press the opposing sides of the artery firmly together. The length of the innominate artery of man is about 1¾ in. to 2 in. The diameter under distention is from 14 to 15 mm. The thickness of the wall during life is 0·51 mm. and when collapsed is 0·98 mm. So that as the distance between the clamps was 3 mm., more than 1 mm. was allowed for the probable increase of thickness in the wall of the patient's innominate.

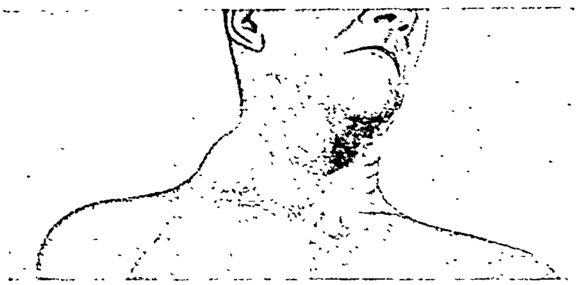

FIG. 1. *Appearance of the right side of neck* (Sept. 1st, 1933).—Prominent egg-shaped swellings occupied the right side of the neck. Expansile pulsation in them was visible and was readily detected by palpation. One large bulge was present in the upper part of the anterior triangle below the right side of the ramus of the jaw; another appeared at the lower part of the posterior triangle with a smaller swelling above it. The sternomastoid muscle was forced forwards especially above the inner end of the clavicle. The outline of the upper border of the clavicle was obscured. The depression of the skin in the region of the left side of the manubrium was caused by the removal of the left half of the manubrium and of the inner extremity of the left clavicle.

On Nov. 4th, 1925, the operation of ligature of the innominate artery was carried out.

The anæsthetic employed was ether and oxygen. The approach was necessarily from the left side. A long median incision was made. The inner extremity of the left clavicle and the left half of the manubrium were removed. This required a section of the cartilages of the left first and second ribs. The removal of these fractions of bone gave an admirable exposure. The edges of the pleura were coaxed away with moist gauze. The upper border of the arch of the aorta was defined and the left innominate vein retracted. In this manner the proximal part of the innominate below the aneurysm came into view. It only remained to apply the clamp or the ligature. But at this moment the difficulty of the operation became very prominent. The innominate was absolutely fixed by the surrounding tissues to which it was adherent. The tumour overlapped the artery above; and below was the arch of the aorta. With much patience and after some time had elapsed the aneurysm needle was passed around the artery. The tissue through which the aneurysm needle passed as it slowly encircled the artery appeared to be scar tissue, and during this time one did not know what catastrophe might not suddenly happen. The inflammatory tissue surrounding the artery was evidence that it was seriously diseased. It soon became clear that it was not possible to pass the clamp round the artery, and three kangaroo tendons were passed round it. The first half of the stay knot was applied and the ends pulled upon strongly. The rigidity and fixation of the arterial wall became then more evident than ever before. The artery was not quite, but nearly, occluded. All the time that the ligatures were being pulled on the possibility of rupture of the arterial wall or the wall of aneurysm at the point where it was continuous with the artery was present to the mind. The stay knot was completed and the wound closed. During the operation Mr. B. C. Maybury gave the most skilful assistance.[4] The pulsation in the neck as a consequence of the operation was not arrested but greatly diminished. In tying the common carotid artery with a stay knot of two strands of kangaroo tendon a pull of 1 lb. will occlude the artery but a pull of 5 lb. is required to rupture the coats. If three strands of kangaroo tendon are used a pull of 1½ lb. will occlude the artery but a pull of 9 lb. is necessary in order to rupture the coats. It will be noticed what a wide range exists between the force which is sufficient to occlude and the force which produces rupture of the coats. Other points of interest are that while the ligature is being tightened the elasticity of the artery assists and later resists; and that the blood pressure is rising as the artery being occluded as it is becoming a diverticulum of the larger artery of which it is a branch. The innominate artery is not quite double the size of the common carotid and the tension of its wall is much greater. The force required to occlude the innominate artery when three strands of kangaroo tendon are employed is about 3 lb., while the force required to rupture the coats is 10 lb. These facts are the result of experiments on the healthy arteries of man. The elasticity and other qualities of the arterial wall are profoundly modified by disease. In the case under review the wall of the innominate artery was thickened, rigid, and fixed to the surrounding tissues which vastly altered in an adverse manner the problem of surgical occlusion.

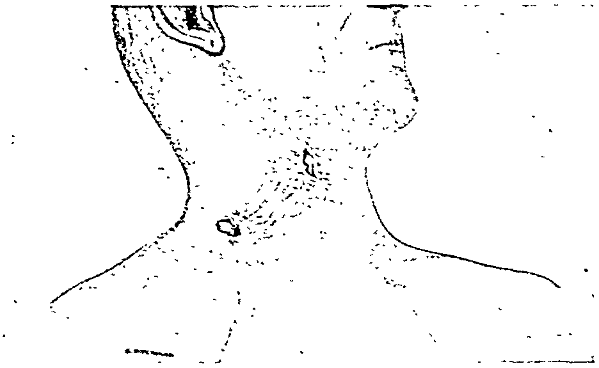

FIG. 2. *Appearance of right side of neck* (Oct. 17th, 1933).—Large masses of clot had been extruded through the openings in the skin. The skin of the neck has fallen in and has resumed its normal position. The outline of the upper border of the clavicle is visible. All pulsation has ceased. The interior of the aneurysm had been dressed daily for two weeks with ribbon gauze soaked in hot Beck's bismuth paste. The ends of the ribbon gauze dressing are seen protruding through the openings in the neck.

As the pulsation was not arrested, on Nov. 28th, 1925, the right common carotid was ligated under local anæsthesia, and on Dec. 8th the first part of the right axillary artery was ligated under local anæsthesia. It was not possible to ligate the third part of the right subclavian artery as the sac of the aneurysm covered it. The pulsation, though lessened, was not arrested by these two ligations. It was thought that the vertebral artery or other branches of the subclavian might be responsible for the continued pulsation, but these vessels were protected from surgical interference by the position of the aneurysmal tumour.

[2] Surgical papers by Halsted, Baltimore, 1924, vol. i., p. 401.

[3] A note on this clamp forms an appendix.

[4] Mitchell Banks, in contrasting the ligation of the innominate artery with ligation of the first part of the subclavian artery, says that it was a mere surgical amusement. (Jacobson's Surgery, 10th edition.) We cannot entirely adopt this view!

On March 29th, 1926, the bulgings of the aneurysmal sac in the anterior and posterior triangles were treated by electrolysis. The effect was local and no general clotting occurred in the tumour. Nevertheless the patient was quite comfortable and seemed much better generally. On Oct. 27th, Nov. 26th, and Dec. 6th, 1926, the electrolysis treatment was repeated. These measures appeared to reduce in size the prominent portions of the aneurysm—the patient was comfortable and the pulsation of the main tumour was slight. During 1927 and 1928 the patient leading a sedentary life was quite well. Towards the end of 1928 there was a slight right hemiplegia but this soon cleared up. From 1928 to June, 1933, patient remained perfectly well while leading a sedentary life.

of this separation; indeed the inter
explanation of the function of the .

In June, 1933, after some physical exertion, pain returned in the upper chest and the right side of the neck. A large swelling gradually developed in the upper part of the anterior triangle, the size of an egg, a little distance from the ramus of the jaw, and another large bulge of the main aneurysmal swelling appeared in the lower half of the posterior triangle. (Fig. 1.) In August, 1933, in spite of absolute rest the skin over these swellings became congested and of a dusky purple colour. As the aneurysm threatened to rupture through the skin the patient was removed to a surgical home in London.

On Sept. 22nd an X ray examination was undertaken. The radiographic screen demonstrated that there was no pulsation at the site of innominate ligation nor in the thoracic portion of the aneurysm. The plates showed the local bulgings of the aneurysmal tumour in the neck. In order to anticipate the rupture through the skin it was decided to inject quinine urethane hydrochloride into the two bulging parts of the aneurysm. This was done on Sept. 12th, 13th, 20th, 22nd, 24th, and 26th, 2 c.cm. of the solution being used for each injection. The result was surprising—the skin over the swellings gave way, large masses of clot were extruded, no hæmorrhage occurred, and *all pulsation in the aneurysm ceased.* (Fig. 2.) The side of the neck became flat. The upper border of the clavicle was visible. On Oct. 15th the nurse reported that in the early morning the patient had some difficulty in speech. This, however, when the patient was seen, had passed away but there remained a complete right hemianopsia. The pulse tended to be rather quick and the temperature was above normal. Since the clot had been extruded the cavity of the aneurysm had been packed daily with ribbon gauze soaked in hot Beck's bismuth paste. The patient was cheerful, the surface of the neck was flat, and all seemed well when hæmorrhage occurred. This was repeated and he died on Oct. 20th.

Discussion

THE ONLY WAY IN WHICH AN ANEURYSM CAN BE CURED

Antonio Scarpa, emeritus professor of surgery in the Imperial and Royal University of Pavia, wrote 130 years ago that—

> "It is a certain and incontrovertible fact in practical surgery that a complete and *radical* cure of aneurism cannot be obtained in whatever part of the body this tumour is situated unless the ulcerated, lacerated or wounded artery from which the aneurism is derived is by the assistance of Nature, or of Nature combined with art, obliterated and converted into a perfectly solid ligamentous substance, for a certain space above and below the place of *ulceration, laceration or wound.*"

Since this bold statement was made its truth has never been disproved. We have failed to find the record of a single case in which cure has taken place in any other way. There does not exist in any museum we have visited a single specimen showing any other mode of cure, and it may be added that any exception to the rule is not to be expected from what is known of the processes which occur in the disease.

FORMATION OF THE ANEURYSM AND CONCERNING THE COAGULUM

The first step in the formation of an aneurysm is the occurrence of some injury or disease in the arterial wall, by which it becomes weakened and yields to the pressure of the blood within. A bulging occurs, round which, as round a foreign body, a capsule forms which constitutes the wall of the aneurysm, but this in its turn is not strong enough to resist the pressure of the blood, and the disease continues to advance. As it does so the shape of the aneurysm alters, and there arise in it bays and backwaters in which the blood circulates but feebly, and finally clotting takes place. As the aneurysm continues to enlarge another layer of clot is deposited internal to the first, and so on, the aneurysm gradually increasing, and successive layers of clot being deposited in its quieter parts. In this way the sac may become filled with laminated clot. Even so the aneurysm is by no means cured. There is a constant danger of the blood finding its way between the wall and the clot. The only thing that can obviate this danger is for the wall to become adherent, and the only way this can occur is by the extension of connective tissue growth from the wall into the clot. This does actually occur at certain parts of the aneurysm, but only at those places where there is perfect stillness, for the slightest movement of the wall on the clot will prevent the invasion of connective tissue cells, and therefore also the necessary adhesion of the clot to the wall. Experience shows there is always too much pulsation in an aneurysm for the adhesive process to be carried out effectively unless the artery on which it is situated is occluded at the site of aneurysm. The reason why the clot in an artery can become adherent is because it entirely fills the artery; all circulation and pulsation is arrested, and stillness is attained. When the same condition is produced in an aneurysm by the occlusion of the artery at the site of aneurysm, adhesion occurs between the wall and the clot. It must be remembered too that the intima of an artery is a more active tissue than the inner layers of the sac of an aneurysm, since in the latter the greater number of plasma cells have passed into a stage of quietude and encystment in fibrous tissue. In fact in an artery, just as in an aneurysm, it is necessary, if adhesion of the clot is to be established, that the vessel be occluded.

If the coagulation extend from the aneurysm into the artery, and this also becomes filled with clot, then all pulsation in the aneurysm ceases, invasion of connective tissue cells occurs over the whole extent of the clot, the absorption and substitution of the clot by connective tissue proceed concurrently throughout the whole thickness of the clot, which, together with the wall, becomes partly absorbed and partly converted into a mass of connective tissue. This gradually shrinks, so that after the lapse of years all that remains of the aneurysm is a small fusiform nodule of connective tissue. This last stage is well seen in John Hunter's fourth case of ligation of the superficial femoral artery for popliteal aneurysm 50 years after ligation. (Hunterian Museum, R.C.S., No. 3259.) In transverse sections of old and large aneurysms the clot is seen to be arranged in a very complicated manner. It is difficult to decipher its history, but the key to the general principle of its growth will be found in the study of the clot in smaller aneurysms and in those which have recently arisen.

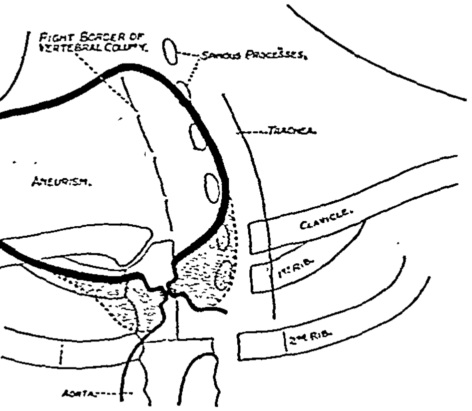

FIG. 5. *A composite diagram in part traced from radiograms.*—1925: The ligation of the proximal part of the innominate artery and the involvement of the distal portion in the aneurysmal tumour is represented. 1933: The innominate artery has disappeared. The aneurysm opens directly into the arch of the aorta. The stippled area shows the extension of the aneurysm in the direction of the aortic arch since 1925. The trachea is displaced to the left of the midline. Displacement and rotation of the vertebræ have taken place. A concavity is thus formed looking toward the right side. The spines of the vertebræ indicate the bend as does also the line of the right border of the vertebral bodies.

THE WALL

The wall of the aneurysm consists of coarse parallel fibres. With a higher power each of these is found to be composed of smaller fibres. Wherever a clot is adherent to the wall, connective tissue growth extends into the clot and the new fibres thus formed become in time part of the wall. (Fig. 3.) The same process occurs when a ligature is absorbed, the new tissue forms in and takes the place of the portion of ligature absorbed, and thus the capsule always closely surrounds the remaining portion of the ligature. Encapsulation does not arrest absorption. The successive fibrous lamellæ forming the wall of an aneurysm are separated by considerable intervals in which all that is seen is a little loose connective tissue. The existence of these wide spaces is due to the pulsation of the aneurysm, and in their presence the capsule of an aneurysm differs from the capsule of all non-pulsating foreign bodies. The capsule is formed under constant movement and is adapted to it. With each pulsation the fluid in the spaces in the wall is displaced, the fibrous lamellæ being pressed together.

EXAMINATION OF THE ANEURYSM

The right common carotid, the right subclavian, and the right vertebral arteries were successively connected with a water-power system (about eight feet high). No trace of fluid entered the cavity of the aneurysm. This was proof that the hæmorrhages could not have come from either of these arteries.

(*a*) *Anterior aspect of the specimen* (Fig. 4).—The arch of the aorta is much thickened and dilated. It measured 5 cm. in diameter instead of the normal 3 cm. The inner surface is irregular and nodular and round the opening of the innominate artery are calcareous plates. The diameter of the aortic opening of the innominate is 30 mm. instead of the normal 15 mm. Looking into the lumen of the innominate artery, or rather what is now the interior of the aneurysm, a concave mass of decolorised clot is visible. Its edges reach the sides of the opening. The concavity presenting towards the aorta is due to the rush of the aortic blood against it. The surprising fact is now revealed that the innominate artery has disappeared. It is in its whole extent the site of aneurysm. The aneurysm is now not an aneurysm of the innominate artery but an aneurysm of the aortic arch. The proximal part of the artery which eight years previously had been ligated and nearly occluded is now absorbed into the aneurysmal tumour, for the lower border of the tumour corresponds to the upper

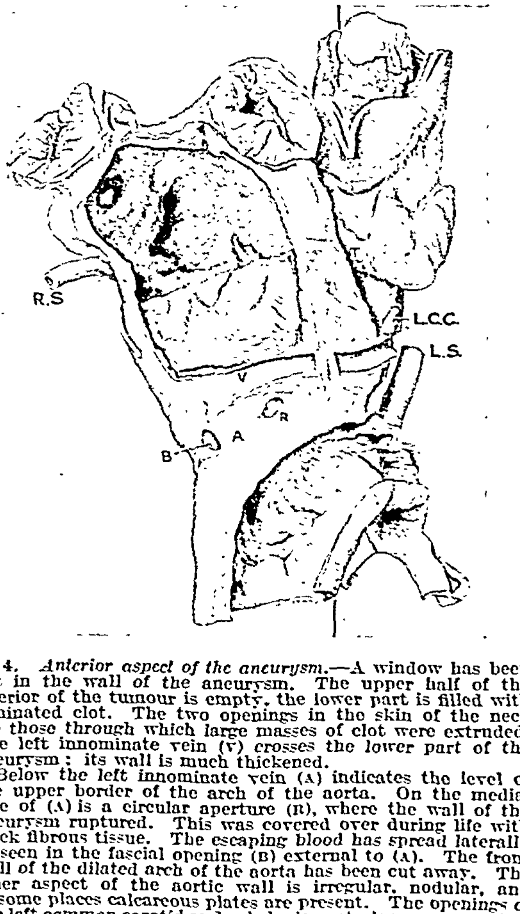

FIG. 4. *Anterior aspect of the aneurysm.*—A window has been cut in the wall of the aneurysm. The upper half of the interior of the tumour is empty, the lower part is filled with laminated clot. The two openings in the skin of the neck are those through which large masses of clot were extruded. The left innominate vein (V) crosses the lower part of the aneurysm: its wall is much thickened.

Below the left innominate vein (A) indicates the level of the upper border of the arch of the aorta. On the medial side of (A) is a circular aperture (R), where the wall of the aneurysm ruptured. This was covered over during life with thick fibrous tissue. The escaping blood has spread laterally as seen in the fascial opening (B) external to (A). The front wall of the dilated arch of the aorta has been cut away. The inner aspect of the aortic wall is irregular, nodular, and in some places calcareous plates are present. The openings of the left common carotid and subclavian arteries are encroached upon by the disease of the aortic wall.

The larynx and trachea are displaced to the left of the median line. The cartilages forming the pomum Adami appear somewhat twisted toward the left side. The right half of the thyroid gland (T) is compressed between the tumour and the cricotracheal region. The innominate artery has disappeared. It has been absorbed into the aneurysm which opens directly into arch of the aorta.

Lines above and below the specimen indicate approximately the middle line. L.S.: Left subclavian artery. R.S.: Right subclavian artery. L.C.C.: Left common carotid artery. (R.C.S. Museum: special pathology section. 5138-2.)

border of the arch of the aorta and the aortic opening of the innominate now leads not into the innominate artery but into the aneurysm. It may be surmised that the artery when ligated was already aneurysmal. (Fig. 5.) The clot in the inferior segment of the aneurysm is remarkably hard and except for an area posteriorly it is *not* adherent to the aneurysmal wall. Thus a narrow chink is present through which at times blood could pass or trickle. In the prepared specimen, from the lower border of the aneurysm to its upper limit in the neck, the measurement is 4½ in. The widest part of the aneurysm in the neck measures 3½ in. and the greatest antero-posterior measurement is 2¾ in. At the lower border of the tumour just above the arch of the aorta the wall had recently given way. This rupture was covered with thick fibrous tissue and if life had continued a new bulge of the aneurysmal tumour or a mediastinal hæmorrhage would have taken place. Above this rupture the left innominate vein spans the tumour. Its wall is greatly thickened.

(*b*) *Posterior aspect of the tumour* (Fig. 6).—The lower part of the tumour is moulded against the inner aspect of the right first rib and the right clavicle to the periosteum to which it is firmly attached. The aneurysm involves the whole length of the innominate artery and the origins of the right common carotid and right subclavian arteries. These latter, where they join the aneurysm, are filled with clot. It was not therefore feasible for hæmorrhage to have occurred from any vessel except the aorta. A window has been cut in the wall of the tumour. It shows the original course and position of the innominate artery. The surface exposed exhibits calcareous degeneration. This must be part of the tissue outside the clot (? tunica intima) since this regressive change does not take place in clot.

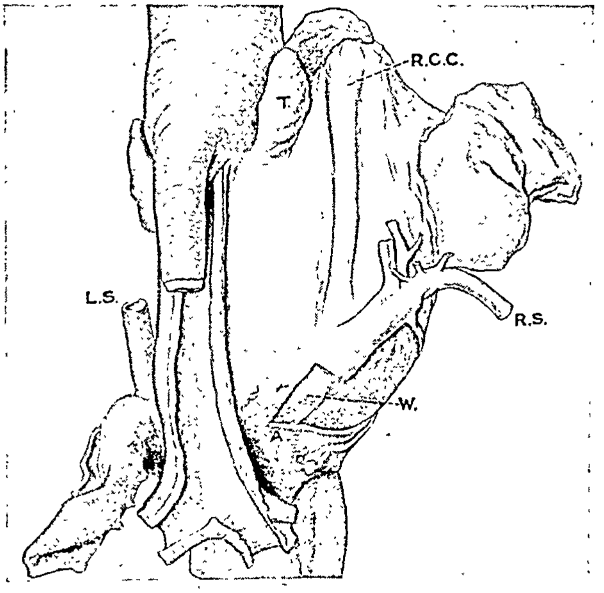

FIG. 6. *Posterior aspect of the aneurysm.*—The origins of the right common carotid and subclavian arteries are involved in the aneurysm. (A) indicates the level of the upper border of the arch of the aorta. A window (W) has been cut in the wall of the aneurysm to indicate the site and course of the innominate artery which has been entirely absorbed into the aneurysmal tumour. (In the drawing the window is shown much foreshortened owing to the fact that the wall of the aneurysm dips down deeply towards (A).) The larynx, trachea, and œsophagus are displaced to the left of the midline. The right half of the thyroid gland (T) is displaced and compressed. L.S.: Left subclavian artery. R.S.: Right subclavian artery. R.C.C.: Right common carotid artery. (R.C.S. Museum: special pathology section. 5438–2.)

THE FOREGOING CONSIDERATIONS AND THEIR APPLICATION

It is clear that the ligation in this case was not followed by the obliteration of the artery, so that as Scarpa's law was not fulfilled cure did not take place. The strong pulsation of the aneurysm was greatly reduced. It is tempting to think that for a time some control was attained over the disease, but the question remains is this conclusion true, or only a sentimental belief? Distal ligations were carried out because at the moment nothing else seemed possible to do for the patient. Distal ligation, however, is a fallacious procedure, for it causes the aneurysm to become a diverticulum of a larger artery and so the pressure within the sac is actually increased rather than diminished. In this case the pressure within the aneurysm became the pressure within the aorta.

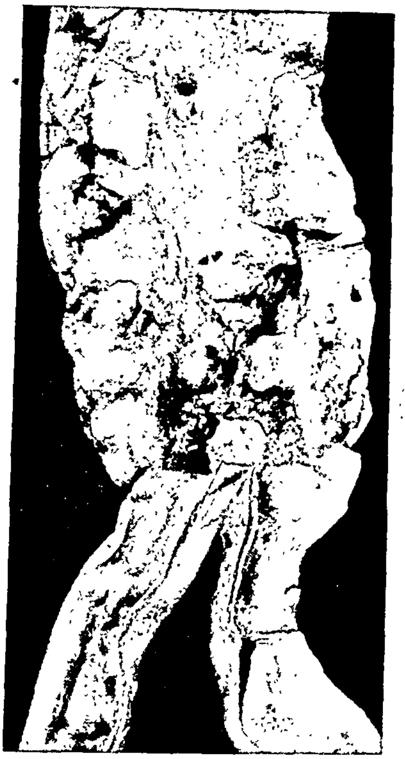

FIG. 7. *Inner aspect of abdominal aorta.*—Above the bifurcation and on the left side is an extensive ulcer (3″ × 1″) surrounded by calcareous plates. On the central side of the above ulcer and on the right side is another smaller ulcer. The remaining surface of the inner wall of the abdominal aorta is extensively diseased. (R.C.S. Museum: special pathology section. 5438–3.)

The tension of the arterial wall is directly proportional to the fluid pressure and to the diameter of the artery. The transverse tension is double the longitudinal. During the last few years of the patient's life the aneurysm became less amenable to treatment by rest and antisyphilitic remedies. This change probably coincided, in part at least, with the alteration in the arterial relations of the tumour. It was for many years an aneurysm of the innominate artery, but during the last years it was directly connected with the aorta—the aortic opening being 30 mm. in diameter. The pressure of the aortic blood is greater than that in the innominate artery. In a spherical aneurysm the tension of the wall is proportional to the fluid pressure and to the diameter of the sphere, but the tension is only half the transverse tension in a cylinder of the same diameter. These considerations explain the rapid rate at which some aneurysms grow and the rupture of others.

The case illustrates the fact that an innominate aneurysm usually commences at the point of strain—namely, the bifurcation—thus leaving the proximal portion of the artery at first unaffected, and making operative interference possible. The aneurysm was in its early stages in large part an aneurysm of the neck. The innominate arises on a level with the upper border of the second right costal cartilage and ascends obliquely upwards, outwards, and backwards. The bifurcation of the innominate is directly behind what Ward calls the superior angle of the inner extremity of the clavicle. The left border of the innominate artery appears in the neck immediately behind the middle of the episternal notch. At this point it is 1¼ in. from the surface, and from this point to the bifurcation (with the head slightly thrown back) measures ⅞ in., so that a good ¾ in. of the artery lies in the neck. The antero-posterior diameter of the upper opening of the thorax in the midline is about 2 in. This enables one to visualise the depth of the aneurysm from the surface when it first arose. The tumour would naturally spread in the direction of least resistance. In our case it spread upwards under the sternomastoid muscle, downwards into the mediastinum, and finally caused bulgings in the upper part of the anterior triangle of the neck and in the lower part of the posterior triangle. Both these sites of bulging are weak regions uncovered by muscle. Though the aneurysm had been present for twenty-three years, the autopsy did not reveal pressure erosion of any bone. There is a full inch of the first part of the right subclavian artery before branches are given off, so that it is easy to understand that the origin of the right subclavian can be involved in and occluded by an aneurysm without interference with the branches, and this is what happened in the case under review.

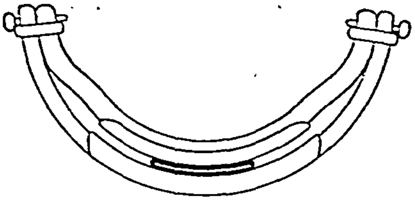

FIG. 9.—The ivory clamp closed and in position (½ nat. length). The inner arterial surfaces are nearly approximated.

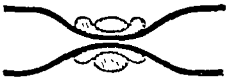

FIG. 10.—A vertical longitudinal section of the clamp and artery.

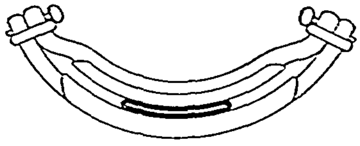

FIG. 11.—The clamp reduced in size (½ nat. length). It was obvious that the rails could be reduced in length without in any way altering the principles on which the clamp was designed. The result is seen in this Figure.

The patient suffered ten days and a week before his death from a moderate or small hæmorrhage which ceased spontaneously. Speculation was rife as to what small vessel was responsible for the bleeding. It was not known that the ligation of the innominate had failed, indeed the reverse appeared to be true, for the radiographic screen demonstrated that there was no pulsation in the chest above the upper border of the arch of the aorta. The bleeding came from the aorta. It is always well, whether the case be one of brain abscess or in this case one of aneurysm, to concentrate on the original site of disease. Otherwise the surgeon "vext with waste dreams" may be led astray and form erroneous ideas.

It was twenty-three years after the patient was infected with syphilis that the diagnosis of innominate aneurysm was made. The aneurysm was under treatment, with long intervals in which relief from symptoms was noted, for twenty-three years. (Fig. 7.) It is noteworthy that in the earlier stages of the disease rest and antisyphilitic treatment were most beneficial.

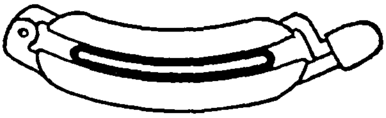

FIG. 12. *Clamp for innominate artery* (natural size).—The normal artery is 15 mm. in diameter. Allowing for enlargement by disease the clamp is designed for an artery 18 mm. in diameter. When flattened this artery would measure 27 mm. after allowing for a loss of length on the return at either end of the flattened artery. Length of saddles 37 mm.—this allows a margin of 5 mm. at either end.

Before the death of the patient the terrible incidence of syphilis on his arterial system was not and could not be known. On the other hand the heart and the valves of the heart were unaffected by disease.

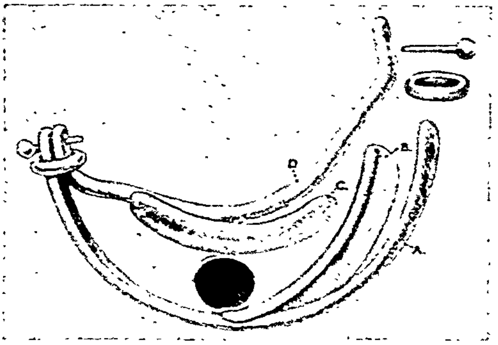

FIG. 8.—Components of the ivory clamp described in text (½ nat. length).

Treatment of the aneurysmal cavity.—The daily changing of the dressing within the aneurysmal sac after the extrusion of masses of clot was probably a wrong method to adopt. It is interesting to speculate what would have happened, for example, whether bleeding would have been prevented, if, when the clots had been extruded, the aneurysmal cavity had been filled with hot Beck's bismuth paste and no other dressing attempted. The frequent changing of the dressing, however gently done, may have displaced or loosened a fragment of clot from a channel leading to the aorta.

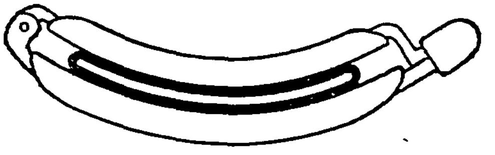

FIG. 13. *Clamp for thoracic or abdominal aorta* (natural size).—The arch of the aorta before the great vessels are given off is 3 cm. in diameter. At the bifurcation of the abdominal aorta the diameter is 1·75 cm. The aorta is diminished in size by the giving off of the large branches from the arch. Assuming that the thoracic aorta (being somewhat enlarged by disease) is 26 mm. in diameter, the flattened artery would measure 39 mm. The length of the saddles is 49 mm. This allows a margin of 5 mm. at either end.

In Figs. 12 and 13 the final design of the clamp is seen, the object being to reduce size and weight. The rails are further reduced in length. The rings and bolts are abolished. At one end a hinge unites the rails. At the other end the rails are brought together by a cap which screws on. The saddles are reduced in length so that they extend only 5 mm. at each end beyond the artery when flattened. The lower saddle still moves in its groove on the rail, but the upper saddle is fixed to its companion rail.

The Weights of Clamps in Ivory and Various Metals: Calculated.

	Clamp for 18 mm. artery (innominate).	Clamp for 26 mm. artery (aorta).
Ivory	1·34 grammes	2·70 grammes
Aluminium	2·41 ,,	3·68 ,,
Stainless steel	7·65 ,,	11·35 ,,
Nickel alloy	8·32 ,,	12·50 ,,
Silver: gold plated	10·50 ,,	15·32 ,,
Gold	18·71 ,,	27·80 ,,
Platinum-iridium	21·85 ,,	32·60 ,,

We are much indebted to Dr. Woods, of the pathological institute at the London Hospital, for the performance of a skilled post-mortem examination.

THE BRAIN

The following report was made by Mr. T. W. P. Lawrence, acting pathological curator of the Hunterian Museum of the Royal College of Surgeons.

The right vertebral artery exhibits a diffuse thickening of its wall, with reduction of the lumen to about one-fifth of its width by an abundant fibrocellular increase of the intima having the microscopical features of a syphilitic endarteritis. Two localised thickenings are present in the basilar artery, one at the bifurcation, the other near the commencement of the vessel. There is a localised area of endarteritis at the termination of the right internal carotid artery and at the commencement of the left middle cerebral artery. Slight atheromatous changes are present in addition in the internal carotid artery. In both vessels the lumen is partly obstructed by recent thrombosis, the clot consisting of a finely granular peripheral deposit next the vessel wall, enclosing a central cavity containing red blood corpuscles and leucocytes.

Recent softening of the grey matter of the cerebral hemispheres has occurred in the following situations: *on the left side*, in the middle two-fourths of the ascending frontal convolution with slight extension into the middle frontal, in the posterior part of the superior frontal convolution, the upper end of the ascending parietal convolution, and the upper part of the occipital lobe adjacent to the longitudinal fissure; *on the right side*, in the hinder part of the superior frontal convolution adjacent to the longitudinal fissure, in a somewhat ill-defined area above the middle of the parietal lobe, in the superior occipital gyrus, and in a small area at the extreme apex of the occipital lobe. In most of these situations there is only slight depression of the surface, but in the left ascending frontal convolution and the right upper occipital gyrus considerable depression has resulted from shrinking of the white substance. The pia-arachnoid over the depressions is slightly opaque; in other situations it is unaltered. In a horizontal section made through the left cerebral hemisphere the internal capsule and basal ganglia are normal in appearance. Microscopical examination of the softened areas of cortex exhibits necrosis and disintegration of the tissue, with reduction in the width of the grey matter, in some places almost to complete disappearance. In some sections a pial arteriole adjacent to the necrosed area is obstructed by a blood clot. The aorta is diseased in its whole length, apparently from a combination of syphilitic disease and atheroma. The aortic valves are normal. (R.C.S. Museum: special pathology section. 4947–2.)

Appendix

THE EVOLUTION OF AN ARTERIAL CLAMP (FIGS. 8–13)

Reference has been made to the intention of applying a clamp in this case for the occlusion of the innominate artery. Halsted has recommended for the occlusion of the innominate artery an aluminium band 1 cm. wide and No. 33 gauge in thickness. In his experiments the band was inveigled round the artery by a roller, the lumen of the band being gradually diminished so that it could act as a ligature. It was seen that if a large artery were occluded in this way the edges of the band might press unduly against the arterial wall, and it was decided to employ an ivory clamp. Such an instrument was manufactured by Messrs. Mayer and Phelps to the design of one of us (C. B.), and trials were made in the post-mortem room.

The idea underlying the design of the ivory clamp was to make an instrument which would bring the inner surfaces of the artery together over a wide area. It was thought also that the diameter of the circle of which the clamp formed an arc should be large. The diameter of the circle was fixed at 10 cm.

The clamp was thus applied.

The lower ivory rail (A) is passed below the artery. The saddle (B), on its grooved side, travels on the rail till its mid-point reaches the middle of the artery. The saddle (C) is then placed on the artery and the upper rail (D) laid in the groove of the saddle. Pressure is now applied to the upper rail till the rings and bolts at the ends of the rails can be fixed in position. When this is accomplished the saddle surfaces are separated by a distance of 3 mm. Each saddle surface lying against the outer wall of the artery is 2 cm. wide. The edges of each saddle are gradually rounded so as to present a smooth and wide surface to the arterial wall.

As will be seen from the record above, the clamp was not employed in this case, but as surgeons may find themselves in the presence of situations where such an instrument might be very useful, it has been thought well to describe it. The model clamp is now in the museum of the Royal College of Surgeons of England.

PREPARATION AND PROPERTIES OF AN ANTITHYROTROPIC SUBSTANCE

By Evelyn M. Anderson, M.D.

AND

J. B. Collip, Ph.D., D.Sc., M.D., F.R.S.
PROFESSOR OF BIOCHEMISTRY AT MCGILL UNIVERSITY, MONTREAL

(From the Department of Biochemistry, McGill University)

We have reported recently[1] the effect of prolonged injections of thyrotropic hormone in the rat; the lowering of the metabolic rate to the level of the hypophysectomised animal and the presence in the serum of these animals of a substance which inhibits the action of the thyrotropic hormone. Since then studies have been made on this inhibitory substance which has been produced in the serum of a horse injected with the thyrotropic hormone.

A 15-year-old mare has been used in this study. The serum from this horse before any thyrotropic hormone was given gave no evidence of inhibiting the effect of the thyrotropic hormone when tested upon the hypophysectomised rat (Table I.). After four weeks of daily intravenous injections the serum showed definite evidence of an antithyrotropic substance. In Table I. it is shown that 2 c.cm. of the serum completely inhibits a dose of thyrotropic hormone which is ten times the minimum effective dose for the hypophysectomised rat.

The effect of this antithyrotropic serum upon the metabolic rate of normal animals has been studied. A group of male rats five weeks old were injected with serum obtained from the horse which had received the thyrotropic hormone for six weeks. Another group received serum from a horse which had been given growth hormone for the same length of time. A third group received normal horse serum. If the metabolic rates of the experimental group in Table II. are compared with those of the two control groups, one sees suggestive evidence that the antithyrotropic serum has had a depressing effect on the metabolic rate of normal rats. We have found in our previous work that fairly large doses of thyrotropic hormone are necessary to raise the metabolic rate of rats; the converse of this may possibly be true—that large

Serum from horse "P" not injected ..	2	1–2	+2	+14	..	+17	− 3	0

This shows the lowering of the metabolic rate by the serum of horse "By" after six weeks' injection of thyrotropic hormone. Normal male rats 5 weeks old were used. The serum from a horse injected with growth hormone for the same period of time, and also normal horse serum, were used as controls.

doses of antithyrotropic substance are necessary to lower the metabolic rate.

We have evidence that the potency of the inhibitory serum can be greatly increased with prolonged injections of large doses of thyrotropic hormone. We have gradually increased the daily dose for the horse from 1000 units of the hormone at the beginning of the injections up to 10,000 units in the course of six weeks.

The antithyrotropic substance has been found to resemble insulin in its solubilities, and extracts of the potent serum have been made which are highly active. The most satisfactory method of preparing native protein-free extracts of the antithyrotropic substance is to precipitate from 92 per cent. acetone the 66 per cent. acetone-soluble substances of the fresh serum. In Table III. are reported the results of experiments in which the extracts of the antithyro-

* Boiled.

It will be noted that extract C not only inhibited 100 units of thyrotropic hormone which were injected daily, but caused an actual lowering of the metabolic rate. Boiling extract C at pH 5 for three minutes destroyed its potency.

The metabolic rates of the hypophysectomised rats averaged 26 per cent. below normal before injections, which is evidence that the pituitary gland is completely removed. The control rat, receiving only thyrotropic hormone, was restored to its normal metabolism. The metabolic rates of two of the animals receiving the antithyrotropic substance dropped to a very low level. In spite of this the thyroid glands showed cellular activity.

tropic serum have been tested against thyrotropic hormone in normal rats. The amount of thyrotropic hormone used was fully five times the minimum effective dose. Extract C shows marked ability not only to inhibit the action of the thyrotropic hormone which was injected, but also to inhibit the thyrotropic hormone of the animal's own pituitary. A lowering of the metabolic rate to minus 26 per cent., which was produced in one instance, corresponds to the lowering of the metabolism which occurs in the hypophysectomised animal.[1] After boiling for three minutes at pH 5, extract C had no inhibitory effect upon the thyrotropic hormone.

	0·04	9	1	+48
	0·08	9	1	+60

The inhibitory action of extract C has been tested also on the hypophysectomised rat. The results are shown in Table IV. The thyroid gland in these hypophysectomised rats showed definite cellular activity which is worthy of special notice in view of the lowered metabolic rate. This is in agreement however, with our earlier observations on a larger group of hypophysectomised rats.[1]

* Pituitary glands from rats treated with thyrotropic hormone for two months.

† Pituitary glands from normal rats.

The antithyrotropic substance has not inhibited the action of thyroxine in raising the metabolic rate. This has been tested on a group of rats which had been injected with thyrotropic hormone over a period of 40 to 70 days, and in which the metabolic rate was below normal. Graded doses of thyroxine, from 0·01 to 0·08 mg. daily, were injected. It will be seen in Table V. that the response to thyroxine characterised by a rise in metabolic rate is practically the same in the thyrotropic-resistant animals as in the control rats. This would indicate that the antithyrotropic substance which we have obtained is quite different from the antithyroidin of Anselmino and Hoffmann.[2] The substance which they describe was obtained in the lipoid-soluble fraction of an extract of normal blood and tissues. They have found that this substance when given by mouth inhibits the action of thyroxine.

The pituitary glands from animals which have received thyrotropic hormone for a long period, and in which the metabolic rates were depressed below normal, have been tested for the presence of thyrotropic hormone. The results of this study are given in Table VI. Three hypophysectomised animals were implanted with pituitary glands from rats which had received thyrotropic hormone for two months. Each animal received five pituitary glands, given over a period of three days. The metabolic rates showed no significant rise over a period of six days. On the sixth day two of these animals were implanted with fresh pituitary of normal rats. This was promptly followed by a rise in metabolic rate. A control rat receiving two normal pituitary glands showed a 30 per cent. increase in metabolism on the third day. The increase in body-weight during the period of treatment with the thyrotropic-free pituitary glands is evidence that the growth hormone was still present.

The question of where the antithyrotropic substance is formed has not yet been investigated. We have evidence, however, that it is not produced by the pituitary gland, for the hypophysectomised rat gives a response similar to that of the normal animal when injected with thyrotropic hormone. In a series of 30 hypophysectomised rats treated with thyrotropic hormone for one to two months the metabolic rate returned after one month to the level observed in untreated hypophysectomised animals.

SUMMARY

An extract of an antithyrotropic substance has been prepared from the serum of a horse which was injected with thyrotropic hormone. This substance has been shown to depress the metabolic rate of normal animals as well as to inhibit the action of thyrotropic hormone in normal and hypophysectomised rats. It does not antagonise the action of thyroxine. Hypophysectomised rats which have received the antithyrotropic substance in conjunction with thyrotropic hormone have a depressed metabolic rate associated with cellular activity in the thyroid gland.

ARTIFICIAL RESPIRATION FOR TWO YEARS

BY PHYLLIS M. TOOKEY KERRIDGE, M.Sc.,
Ph.D. Lond., M.R.C.S. Eng.

ASSISTANT IN THE DEPARTMENT OF INDUSTRIAL PHYSIOLOGY,
LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE;
LECTURER IN THE DEPARTMENT OF PHYSIOLOGY
AND BIOCHEMISTRY, UNIVERSITY COLLEGE,
LONDON

(From the Department of Industrial Physiology, London School of Hygiene)

THE case to be described is perhaps unique in medical history in that artificial respiration has been applied successfully and by unconventional methods for over two years.

The patient is a man of 63, who in 1926 felt loss of power in his fingers occasionally when he was driving a car or writing, especially when his hands were cold. Some months later he noticed that his shoulder muscles were thinner, so that he could feel his bones when carrying anything on his shoulder. In 1927 he noticed transient loss of power in his legs, but he was able to carry on his usual outdoor occupations until one day he attempted to jump from a bus and fell to the ground, as he was unable to control his legs. He was in bed some weeks and was seen by several doctors, who all diagnosed progressive muscular atrophy. Since that time the loss of function in his muscles has been slowly progressive, punctuated with temporary improvements and remissions of variable length. Complete loss of power occurred in his legs before his fingers. He had painless fibrillation in his muscles. He gradually lost weight. He could always feel pain and heat and cold, and he thinks that these sensations are more acute than formerly. There has been no incontinence of urine or fæces. In 1931 he noticed that occasionally he needed to help his breathing by pressing on his chest. In August, 1931, he had a serious attack of difficulty in breathing when riding in a car to which he had been carried. This was relieved by his companions performing artificial respiration by pressing rhythmically on the front of his chest. They were unable to perform it according to the Schäfer method, which they knew, because they could not shift a heavy paralysed man. Their efforts were successful, and the patient recovered his power of breathing after some minutes.

---

[2] Anselmino, K. J., and Hoffmann, F.: Klin. Woch., 1933, xii., 99.

From this time onwards attacks of respiratory difficulty recurred, and were treated by his family in the same way. Gradually the attacks lengthened and the intervals shortened, until in June, 1932, he was having artificial respiration continuously day and night, performed in the same way by relays of relatives and nurses. This continued until September, 1933, when his friend, Sir William Bragg, O.M., F.R.S., suggested that some mechanical device might be substituted for this human effort. Sir William Bragg took two football bladders connected by a wide rubber tube, and while one was bandaged tightly to the man's chest, the other was fixed between two hinged boards, and one of these was fixed to the floor while the other was moved rhythmically by the foot or with a hand lever. This apparatus succeeded beyond all expectation from the patient's and the nurses' points of view. The football bladder lasted only three days as the rubber burst, and it was replaced by a hot-water bottle with the cork and tube through the top, used as an air-bag. These each lasted three weeks, after which they were replaced or patched. The boards were used until the hinges wore loose. A more substantial apparatus on the same principle was made by a firm of organ builders, but this proved too hard for the nurses to work. There was no electric supply available.

At Sir William Bragg's request, Mr. R. W. Paul, M.I.E.E., designed and constructed a small hydraulic machine worked off the main water-supply, which alternately compressed and relaxed a thick rubber bellows. This apparatus has been in successful use since October, 1933, except when on one occasion the water froze in the pipes. It was not in use for the full 24 hours each day at first as the patient could not bear the constriction of the bandage for more than 17 hours, so the original manual method was used for the remainder of the day. The air-bag was fixed over the left side of the front of the chest only. The front was used because it had originally been successful, and because the patient did not wish to live prone, and the left side only because an old injury made the right side hypersensitive to pressure. The patient found by experience that both sides of the chest and the abdomen moved even when pressure was applied to the chest very locally.

The hot-water bottle and binder have now been replaced, at my suggestion, by a belt of two layers of strong linen, interlined with a bag of thick rubber, with a tube coming from the lower front corner. The bag is of a size to surround the front and back of the left side of the thorax only. Both sides were not used on account of the desire to make changes slowly, especially as it was uncertain to what extent the right lung had been in action for some time. The larger area of this bag enabled a lower pressure to be used, and the belt is much looser than the bandage was. He has worn this comfortably and continuously, except when he is washed, for several weeks. With the hot-water bottle he found he required 1·2 lb. per sq. in. pressure, 22 times a minute, and 1·6 lb. per sq. in. if he wanted to talk a lot. With the larger bag 0·9–1 lb. per sq. in. was sufficient.

In his present condition the patient is very active mentally. He lies on his right side almost continuously, as he is not comfortable otherwise. He is very wasted. He is almost completely paralysed. He can, with effort, move the fingers of his right hand and the toes of his right foot. His speech is said not to be as clear as formerly. He has slight difficulty with swallowing. His appetite is good, but he finds he can manage liquids or solids alone at a meal better than both together. Pills are no longer given. His skin is loose on account of the loss of flesh, but is in good condition, and there have never been any bedsores. He says he has fibrillation sometimes in the region of the mouth, but now nowhere else. No supinator, knee, or ankle reflexes could be obtained. There is no sphincter disturbance. Normal breath sounds were heard on the front of the chest on both sides. Complete examination was impossible on account of the continuous artificial respiration. When the artificial respiration was stopped for one minute there was no movement at all in thorax or abdomen.

He had no serious illness previously. As a schoolboy he had a fall on his back which caused him to stay in bed some weeks. He complained of pain in the back in adult life. He led an active outdoor life up to the time of the present illness. He lost an eye due to an accident as a young man.

The method of artificial respiration by compression of the thorax was recommended by Dalrymple, and was the official method of the Royal Humane Society from 1833 until 1861, when Silvester's method was adopted. It was recommended that a drowned person should be laid on his back and a wide bandage passed beneath him, its ends being crossed in front of the chest. An operator on each side of the body constricted the thorax by pulling on the crossed ends, then relaxing their hold and allowing a recoil and inspiration to occur. In Schäfer's method, which is the classical emergency method in use to-day, positive pressure to promote expiration is employed, but instead of applying the pressure to the thorax, when properly executed pressure over the floating ribs compresses the abdominal contents against the diaphragm. The method has the advantage for emergency work that the supine position makes the tongue fall forward and keeps the airway clear. It is said that 50–90 lb. pressure is necessary for the Schäfer method. This is of the same order as that being used by this patient, with 1·2 lb. per sq. in. and a hot-water bottle 12 × 6 in.—i.e., 86 lb. With the larger air-bag, 15 × 10 in. and a pressure of 0·9 lb. per sq. in. the pressure is 135 lb. This is larger probably because part of the bag covers the less movable upper back part of the thorax and functions merely as an air cushion.

The positive pressure methods of artificial respiration have been supposed to work partly on account of the distortion of the shape of the thorax and diaphragm and their ability to recoil, and partly due to the nervous reflex by which an inspiration follows an expiration. In the present case the nervous reflex element cannot be helping on account of the nature of the lesion. Various methods have been suggested and used for prolonged artificial respiration in which the patient is put wholly or partly in a box or chamber in which the pressures can be altered (Thunberg,[2] Doe,[3] Steuart,[4] Eisenmenger,[5] Drinker and Shaw [6]). Negative pressure methods are theoretically more physiological, since inspiration is the active muscular phase in natural respiration The most interesting and instructive point about the present case is that positive pressure can be used without apparent ill-effects for a long period. The comfort of the patient and the simplicity and cheapness of the mechanism in the present case is very striking. The patient is in his own bed, carrying on his normal intellectual pursuits, and there are no nursing difficulties.

With a view to future development, the present method is being further investigated. A simple apparatus, which is electrically driven, has already been constructed.

I am indebted to Dr. W. T. Mills for permission to publish the particulars of his patient, and to the patient and his wife for their permission, interest, and help.

PSEUDO-EPHEDRINE IN ASTHMA[1]

By G. W. BRAY, M.B. Sydney, M.R.C.P. Lond.
ASTHMA RESEARCH FELLOW, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON; AND

L. J. WITTS, M.D. Manch., F.R.C.P. Lond.
ASSISTANT PHYSICIAN TO GUY'S HOSPITAL, LONDON; WILL EDMONDS CLINICAL RESEARCH FELLOW

AT the request of the Therapeutic Trials Committee of the Medical Research Council, we have carried out comparative clinical tests of the therapeutic value of ephedrine and pseudo-ephedrine[2] in asthma. The graphic formula of ephedrine contains two asymmetric carbon atoms, so that two sets of stereoisomers, making six in all, are possible. Only two occur in nature, *l-ephedrine*, which is the ephedrine in general use, and *d-pseudo-ephedrine*, which is usually known as pseudo-ephedrine. Different species of the ephedra plant contain different amounts of these two alkaloids, and there would be a great saving in cost if they could be used interchangeably. It has hitherto been believed that the action of pseudo-ephedrine is identical with that of ephedrine, but weaker (Chen and Schmidt, 1930).[3] In 1931, however, Chopra and co-workers[4] reported that ephedrine and pseudo-ephedrine were equally effective in the treatment of asthma, but that the latter caused fewer unpleasant side actions. This is the statement we have endeavoured to test.

Ephedrine is of little assistance in a severe paroxysm of asthma or in the status asthmaticus; but it usually aborts a mild attack if taken early, and it usually relieves a moderate dyspnœa. It is therefore a valuable drug in the treatment of asthma, as an intelligent patient can often stave off a severe attack by its use. The unpleasant side actions of ephedrine are familiar to all who treat asthmatic patients. Most common are palpitations, trembling, weakness, sweating, feelings of warmth, chilly sensations, nausea, and vomiting, and the tousse émétique. Less common are nervousness, headache, insomnia, dyspnœa, a tired feeling, thirst, drowsiness, precordial pain or distress, flushing, tingling or numbness of the extremities, anorexia, constipation, diuresis, and dysuria. These side actions are most evident at the beginning of treatment with ephedrine, and it is usual for tolerance to them to be developed and, for the patient to be able to continue the use of ephedrine with relief of the asthma and without the unpleasant side actions. In rare instances, however, toxic symptoms suddenly appear in a patient who has tolerated ephedrine well for months or years.

In the following experiments the relative value of ephedrine and pseudo-ephedrine has been assessed in two ways: (1) by the diminution in the number of attacks produced by continuous administration of the drugs; and (2) by the relief of the actual paroxysm by the administration of the drug at the onset of the attack.

PREVENTION OF ATTACKS

These experiments were carried out by one of us (G. W. B.) at the asthma clinic at the Hospital for Sick Children, Great Ormond-street, W.C. Twenty children, 12 boys and 8 girls, aged from four to nine years, were chosen who had (*a*) had their asthma for at least two years, (*b*) had attacks more or less all the year round, and (*c*) had not previously had hospital treatment. These children were divided into four groups of 5 children and observed during alternate control periods, periods while taking ephedrine regularly, and periods whilst taking pseudo-ephedrine regularly. The dosage employed was a quarter of a grain morning and evening for a child under seven years, and gr. ½ morning and evening for a child over seven years. The mothers were instructed to give an additional tablet whenever an attack threatened. During the control period all the children had two teaspoonfuls of water just coloured with burnt sugar three times a day. No other treatment, anti-asthmatic or otherwise, was given.

Group 1 had four months control period, four months on pseudo-ephedrine, and four months on ephedrine.

Group 2 had four months control period, four months on ephedrine, and four months on pseudo-ephedrine.

Group 3 had two months control period, two months pseudo-ephedrine, two months ephedrine, two months pseudo-ephedrine, two months ephedrine, and two months pseudo-ephedrine.

Group 4 had two months control period, two months ephedrine, two months pseudo-ephedrine, two months ephedrine, two months pseudo-ephedrine, and two months ephedrine.

By this means it was possible to compare the efficacy of the drugs with each other and with a control period without anti-asthmatic treatment, and at the same time to eliminate any seasonal variations that might occur.

[4] Chopra, R. N., Krishna, S., and Ghose, T. P.: Indian Jour. Med. Research, 1931, xix., 177.

The results are summarised in the accompanying Tables. Each figure represents the number of attacks of asthma during one month. The figures at the base of each group represent the total number of attacks the five children had during the month, and the single figure the total number of attacks the five children had during the control period, the period on ephedrine, or the period on pseudo-ephedrine as the case may be. The marginal figures represent the sex and age of the child.

In summary, the 20 cases during twelve months control period had 49 attacks; in eighteen months on ephedrine they had 78 attacks; and in eighteen months on pseudo-ephedrine they had 52 attacks.

Or, expressing the figures in the same ratio as regards time, control: ephedrine: pseudo-ephedrine = 100: 107: 73. In other words, whilst the administration of ephedrine did not diminish the number of attacks the administration of pseudo-ephedrine to the same cases and during the same period showed a 27 per cent. reduction of the number of attacks. As regards the severity of the attacks, they were most severe in the control periods, less severe whilst taking ephedrine, and least severe whilst taking pseudo-ephedrine in almost all cases.

Hence one may conclude that pseudo-ephedrine is a more efficacious drug than ephedrine in lessening the frequency of the attacks. Neither drug, if continuously administered, will prevent asthma. In two cases the asthma remained continuous in spite of gr. ½ three times a day in children of seven years. Hence, as both ephedrine and pseudo-ephedrine were used, and the attacks ceased immediately after 5 minims of adrenaline chloride solution had been given hypodermically, neither can replace adrenaline in allaying a severe attack.

One girl of ten years always had sickness and palpitation whilst taking ephedrine but not on pseudo-ephedrine. A boy aged eight years was always made sick by ephedrine gr. ½ but could take the same dose of pseudo-ephedrine quite well. A male of seven years became sick, languid, and listless after ephedrine gr. ½, and complained of palpitation each time. He took pseudo-ephedrine gr. ½ night and morning quite well for two months during which time he had one severe attack lasting four days. Though no sickness or palpitation occurred between attacks, during attacks the tablets made him sick each time for a quarter of an hour, but there was no palpitation. Hence one may conclude that pseudo-ephedrine is less toxic to children than ephedrine in the same dosage.

RELIEF OF PAROXYSMS

These experiments were carried out by L. J. Witts at the asthma research clinic at Guy's Hospital. The standard dose of ephedrine hydrochloride was gr. ½, to be taken as early as possible in the attack and to be repeated at hourly intervals if necessary until grs. 1½ had been taken. If relief was not obtained with this dosage it was rarely possible to improve the results by increasing the dose, on account of the supervention of toxic symptoms. In a few cases, however, the patient had an unusual tolerance for ephedrine, and occasional patients have taken as much as grs. 9 a day with benefit. An analysis of 60 adult patients, who used ephedrine in this way, was as follows:—

28 were relieved by ephedrine and experienced no unpleasant side actions.
23 were relieved by ephedrine but experienced unpleasant side actions.
7 were unable to take ephedrine on account of the severity of the reactions.
2 were totally unaffected by ephedrine.

It was soon found that pseudo-ephedrine had a weaker action then ephedrine. The standard dose of pseudo-ephedrine was therefore fixed at gr. 1, repeated at hourly intervals, if necessary, until grs. 3 had been taken. It was seldom possible for the patient to take a total of more than grs. 4½ of pseudo-ephedrine during an attack without the supervention of toxic symptoms. Reactions to pseudo-ephedrine, when a dosage larger than the standard was employed, were sensations of cold, shivering, dilatation of the pupils, insomnia, lack of energy, drowsiness, palpitation, nausea and vomiting, and dysuria. The side actions of pseudo-ephedrine are therefore the same as those of ephedrine, but nausea and vomiting are more common.

In the first place the therapeutic effect of pseudo-ephedrine was studied in 21 adult patients, who had previously used ephedrine. In 15 of these 21 patients the asthma was relieved by ephedrine, but there were moderately unpleasant reactions ; the remaining 6 patients were unable to take ephedrine on account of the severity of the side actions. The results with pseudo-ephedrine in these 21 cases were as follows :—

3 obtained relief from their asthma without any side actions.
5 obtained only slight relief from their asthma, but there were not side actions. Nevertheless these 5 patients preferred the stronger therapeutic action of ephedrine in spite of its disadvantages.
6 were unaffected by pseudo-ephedrine, either favourably or unfavourably.
7 experienced unpleasant side actions, and did not get the same relief of their asthma as with ephedrine.

These results were disappointing, for it had been hoped that pseudo-ephedrine might be a valuable substitute for ephedrine in patients who had experienced the unpleasant side actions of ephedrine. Of the 21 patients in whom ephedrine had produced mild or severe side actions or had failed to give relief, only 4 preferred the action of pseudo-ephedrine. And of 6 patients, who were completely intolerant of ephedrine, only 1 was relieved by pseudo-ephedrine. The test to which pseudo-ephedrine was submitted in this experiment was severe, for the patients were selected by the criterion that they had experienced unpleasant reactions with ephedrine. Pseudo-ephedrine was therefore prescribed to a second group of 10 cases, of whom 7 had not previously used ephedrine or pseudo-ephedrine, and 3 had been relieved by ephedrine without reactions. The results in these 10 cases were as follows :—

4 were relieved without reaction.
2 were slightly relieved without reaction.
2 were entirely unaffected by pseudo-ephedrine.
2 were not relieved and experienced unpleasant reactions.

The number of our cases is too small for percentages to have any great significance, but it would appear that ephedrine gives relief in about 85 per cent. of adult asthmatics and unpleasant reactions in 50 per cent. ; pseudo-ephedrine gives relief in about 60 per cent. of adult asthmatics and unpleasant reactions in 20 per cent. The therapeutic efficiency of these drugs is rather closely correlated with their toxicity, but in a few patients pseudo-ephedrine will relieve the asthmatic paroxysms when ephedrine has had to be abandoned on account of its unpleasant side actions.

CONCLUSIONS

(1) Pseudo-ephedrine given by the mouth was more efficacious than ephedrine in lessening the frequency of attacks of asthma in childhood. (2) Pseudo-ephedrine was less efficacious than ephedrine in relieving the actual asthmatic paroxysm in adults. (3) Pseudo-ephedrine is less toxic than ephedrine, but in large doses it may produce the same unpleasant side actions. (4) Pseudo-ephedrine is worthy of further trial in the treatment of asthma in childhood, and in the treatment of adults who are unable to tolerate ephedrine. (5) Neither ephedrine nor pseudo-ephedrine is as effective as injections of adrenaline in the treatment of the asthmatic attack.

EFFECTS OF TONSILLECTOMY ON ANTITOXIC IMMUNITY TO DIPHTHERIA
IN A RURAL POPULATION *

BY W. ALFRED BUICE, M.D., Dr. P.H.

DEPARTMENT OF BACTERIOLOGY AND HYGIENE, THE STATE COLLEGE OF WASHINGTON, PULLMAN, WASHINGTON

IN 1916 Tomlin[1] suggested that tonsillectomy might reduce the incidence of diphtheria by eliminating a portal of entry for the bacillus and reducing the number of carriers of the organism. Following this suggestion, a number of clinical writers asserted they had never seen, or rarely had seen, diphtheria in children with tonsils removed. These statements were mere impressions, remembrances, or lack of remembrances, as the case might have been. They did not originate in carefully kept statistics. But in 1924 we began to deal with statistics carefully maintained.

In that year Doull,[2] working in the Baltimore schools, studied 224 cases of diphtheria. Of those 224 cases only 2 had been tonsillectomised. Doull says: "This is a very much smaller number than would be expected in a sample of this size selected at random from the school population. On such a basis the number to have been expected was 26."

In 1927 Collins and Sydenstricker,[3] in an epidemiological and statistical study of tonsillitis among school-children of Hagerstown, Md., reported that diphtheria was found 4·6 times more frequently among children whose tonsils were diseased than among those whose tonsils were removed.

Schick and Topper[4] in 1929 reported that of 300 tonsillectomised children in New York City, 81 per cent. were antitoxically immune to diphtheria, as determined by the Schick test. These children varied from two to twelve years of age. They were charity patients, and came from a highly congested area of the city. On the basis of their findings, Schick and Topper suggested that with more investigation it might be found expedient to resort to tonsillectomy to immunise against diphtheria.

Doull and Herman,[5] also in 1929, made some observations on adults which they have never published. They Schick-tested 232 medical students at Johns Hopkins University, their ages varying between 20 and 29 years. No significant difference was noted in the proportion of immunes among the tonsillectomised and among those with tonsils intact.

Geddie,[6] at the Mayo Clinic in 1930, tested 883 children of Rochester, Minn. Ages varied from one to eighteen. He reported no influence exerted by tonsillectomy on antitoxic immunity to diphtheria.

In 1931 Wheeler, Doull, and Frost[5] reported on a total of 710 children of the Baltimore schools. The children tested varied in age from five to fifteen. These authors reported no significant difference in proportions of antitoxic immunes among the tonsillectomised and among those with tonsils intact.

Shaw[7] Schick-tested 174 Chicago children in 1932. Of 155 in possession of tonsils, 31 per cent. showed antitoxic immunity. Of 19 without tonsils, 33 per cent. were immune.

In 1932 Bigler[8] also tested 470 children of Chicago. The subjects were tested before and after tonsillectomies were performed. Tests made six to nine months after the operations revealed that tonsillectomy and adenoidectomy exerted but little, if any, effect on immunity.

Dudley,[9] in a semi-isolated but not rural community (Greenwich Hospital School) in England, in 1931 reported the frequency of immunes in a tonsillectomised group was twice as large as in a group with tonsils not removed. He thinks that tonsillectomy in itself does not immunise but that in some way it accelerates latent immunisation by the diphtheria bacilli in the environment.

Burton and Balmain,[10] also in England, tested 682 children at Ilford (pop. 131,000) in 1931. They saw no

---

* The writer is indebted to Messrs. Parke, Davis and Co. for the toxin used in the Schick tests recorded in this paper.

influence on immunity to diphtheria produced by removal of the tonsils of children in a residential, non-rural, non-congested area.

In Germany, Orosz and Kugler[11] in 1931 examined 161 tonsillectomised children between the ages of one and six. They found no relationship existing between tonsillectomy and immunity to diphtheria. They consider that fluctuations in the negativity of Schick reactions vary because of changing epidemiologic conditions at different times.

In October, 1932, Park and Kereszturi read a paper on the subject at hand in the annual meeting of the American Public Health Association at Washington. In a personal communication, Dr. Park says they noted no statistical difference in New York City children who had tonsils removed and who had tonsils intact.

Summarising, the data obtained by Schick and Topper and those of Dudley indicate that tonsillectomy immunises against diphtheria, but the findings in each of the other investigations do not indicate that the surgical operation results in such immunity. All these investigations were done in cities, except that of Geddie made in Rochester, Minn., which has a population of 20,000.

THE TESTS AT PULLMAN

The community.—The results being reported in the present paper were obtained in a rural or semi-rural population. These results were observed among school-children at Pullman, Washington. Pullman has a permanent population of 3400 and a college population of 3000 students who reside there from September to June inclusive. The town is located in a fairly densely populated wheat farming country of extreme eastern Washington, within five miles of the Idaho boundary. Many of the children in Pullman schools are transported daily from their farm homes. Nearly all the children are of Anglo-Saxon stock. Pullman is 80 miles removed from any town of consequence, and the population, therefore, has but little contact with urban populations. Only seven cases of diphtheria have been observed in the community during the last eight years. No case had been noted for two years preceding the tests.

Results.—A glance at Table I. reveals that Schick-positives were dominant over the negatives among those children having tonsils removed. The positives were also dominant in the children who had retained their tonsils. In each instance the percentage of positives was about twice as large as that of the negatives.

TABLE I.—*Comparison of Schick-positives with Schick-negatives in the tonsillectomised and in those whose tonsils were intact*

—	Number and per cent.
Tonsils removed—	
Schick-negative	42 (38)
Schick-positive	68 (62)
Tonsils intact—	
Schick-negative	38 (31)
Schick-positive	84 (69)
Total number tested ..	232

Table II. is an analysis by age of the children whose tonsils had been removed. It will be noted that the Schick-positives are dominant at all ages, which is in contrast with the findings of Schick and Topper[4] in New York City, but in agreement with Burton and Balmain's[10] observations among city children in England. This table indicates that tonsillectomy in itself does not immunise against diphtheria. The children of this rural community, with but little contact with urban populations, remain predominantly Schick-positive regardless of increasing age.

Table III. shows the percentage of Schick-positives found in the Pullman studies as compared with the percentage found by Zingher[12] in New York City, without regard to tonsillectomy. (Several other investigators working in large cities have agreed with Zingher.) Of course, at Pullman we are dealing with exceedingly small numbers, as compared with Zingher's. Yet, we are struck with the quite consistent trend of the positives, the general direction being toward greater percentage of positives with increasing age, as opposed to New York's decreasing percentage. To say the least, it does not appear that children in this rural community where diphtheria pays infrequent visits are attaining immunity as they grow older. It is hoped that we shall be able to present observations later to show the trend in Pullman at ages above 13, that is, through the high-school ages.

TABLE II.—*Analysis of the tonsillectomised by age*

Ages.	Number tonsillectomised.	Schick-positive. Number and per cent.	Schick-negative. Number and per cent.
6– 7	12	8 (66·6)	4 (33·4)
8– 9	37	22 (59·5)	15 (40·5)
10–11	43	28 (65·1)	15 (34·9)
12–13	18	11 (61·1)	7 (38·9)
Totals ..	110	69	41

Zingher found that children in the less congested areas of New York City showed 100 per cent. to 200 per cent. more positives than those in the more crowded areas.

Kidder,[13] working in a rural section of the State of Vermont where diphtheria prevailed yearly, showed Schick-positives in school-children there to be much greater in percentage than found by Zingher and others in large cities. Kidder's percentage of positives decreased with increasing age as follows: ages 5 to 9, 81·4 per cent. positive; 10 to 14, 75·4 per cent.; 15 to 19, 65·1 per cent. Children in the villages were 60 per cent. to 71 per cent. positive; while those residing outside of villages were 80 per cent. to 90 per cent. positive.

In Australia, Ferguson and Morgan,[14] working in towns "of less than 10,000 population" where diphtheria was rather rampant, found that an average of about 26·5 per cent. of school-children were Schick-positive. The percentage positive remained on an approximate level with increasing age.

TABLE III.—*Comparison of results of Schick reactions at Pullman with those in New York City as found by Zingher, disregarding the tonsillectomy factor*

Age.	New York City. Number tested.	New York City. Schick-pos. (per cent.).	Pullman, Washington. Number tested.	Pullman, Washington. Schick-pos. (per cent.).	Age.	New York City. Number tested. 10	18,057	29·3	46	73·9					

SUMMARY AND CONCLUSIONS

Rural school-children to the number of 232 were given the Schick test. They varied in age from six to fifteen years. Of the tonsillectomised, 68 (62 per cent.) were Schick-positive. Of those with tonsils intact, 84 (69 per cent.) were positive. Since we are dealing with small numbers this difference in percentage is not regarded as significant. Tonsillectomy does not appear to immunise children of this rural and much isolated community, in which only seven cases of diphtheria have appeared during the last eight years and in which no case of the disease was noted for two years prior to the beginning of the tests.

The proportion of Schick-positives among both tonsillectomised and non-tonsillectomised remained practically on a level through all age-groups. The children, without regard to the tonsillectomy factor, do not appear to be acquiring immunity to diphtheria as they grow older, which is in contrast with the findings of Zingher and other investigators working among children in large cities.

As one studies the figures obtained by Zingher, those obtained by Ferguson and Morgan, those of Kidder, and those of the tests at Pullman, it appears that the smaller the community and the less prevalent diphtheria the greater the proportion of Schick-positives at all ages.

MEDICAL SOCIETIES

WEST LONDON MEDICO-CHIRURGICAL SOCIETY

AT a meeting of this society on April 6th, with Mr. H. TYRRELL-GRAY in the chair, Mr. B. SANGSTER SIMMONDS opened a discussion on the

Future of Nursing-homes and Private Wards in Hospitals

Formerly, he said, we were born, nursed, operated upon, and died at home; now there was a growing tendency for disease to be investigated and operations to be performed in institutions. Nursing-homes were available for those who could afford them, and some of the London hospitals had begun to set aside pay-beds, or had built wards for private patients, with accommodation at from 4 to 8 guineas a week. The number of these beds was still small, and hardly touched the problem of the patient of moderate means, but as hospital pay-beds increased the smaller nursing-homes would gradually feel the pinch and would ultimately disappear. The problem of accommodation for middle-class patients was therefore likely to increase rather than to diminish. Could the hospitals produce enough accommodation at moderate rates—say at 7 guineas a week—to provide for these patients? The luxury nursing-homes could not make a profit if they charged less than 12 guineas a week; at the London Clinic and Nursing Home it was possible to charge 10 guineas. Recently a scheme had been put forward to build a nursing-home of 600 beds to be available at 7 guineas a week with no extras; this could not be a success, he considered, unless it attracted a proportion of patients with chronic types of disease. The economic size for a nursing-home of the kind must be discussed; probably 600 beds were too many, 30 too few. When the economic size had been determined it might be possible to charge only 7 guineas in a mid-London area, but in the suburbs and provinces the cost would be greater. If built by private enterprise such homes should be established on the group system, with a parent institute in the West End and subsidiary homes in the suburbs. The other alternative was an extension of the pay-bed system at hospitals; the voluntary hospitals could probably provide accommodation at 7 guineas a week and make a profit. The present system was undesirable, however, in that the patient was taken from the care of his own doctor and placed under a member of the hospital staff. Was there any reason why the patient should not be treated by anyone he pleased, provided he was paying the whole cost, and that the hospital took no responsibility for treatment? Hospitals might well build extensions where general practitioners and consultants alike could send their patients and treat them. This was the principle followed at nursing-homes and at hospitals in the provinces and elsewhere in the Empire; why should it not be followed in London?

Dr. E. A. GREGG said that the hospitals had encroached so much on general practice that doctors were likely to look on any extension of hospital activities with suspicion. The medical profession had no right to claim anything which did not result in advantage to the community. How far would the scheme just outlined increase the efficiency of the general practitioner service? Probably considerably, if all that Mr. Simmonds had suggested came about, but Dr. Gregg was not sure whether it would. If the whole medical profession could coöperate in building nursing-homes of the right type it would solve the difficulty, but he doubted whether the best results would be obtained by approaching the scheme from the financial angle. Possibly we were pampering the public too much financially; the working class, for example, could afford wireless sets and visits to the cinema, but they had the idea that they ought not to pay for doctoring. The British Provident Association helped patients of moderate means to insure against illness, and the insurance principle might be developed to cover general practitioner services. Under any extension of hospital activities there was a grave danger that the general practitioner would be relegated to the position he now held in relation to pay-beds—he would have to resign the treatment of the patient to somebody else. He thought the medical profession should discuss the question thoroughly before recommending any scheme to the public.

Mr. W. MCADAM ECCLES said that there were 1300 pay-beds in connexion with 140 voluntary hospitals in the area covered by the King Edward Hospital Fund, and this number was totally inadequate for the number of people, in the same area, with intermediate incomes; probably three times as many beds were needed. Further accommodation of the kind could be provided either in wards attached to voluntary hospitals or in specially built home-hospitals in which the general practitioner could look after his own patients. In building such hospitals it would be necessary to provide for capital expenditure, upkeep, and a sinking fund. The British Provident Association was making provision for capital expenditure by means of its Founders' scheme. In an area, such as Ealing for instance, where there were 10,000 people of this intermediate class, 2 yearly in every 100 would need institutional treatment under their general practitioners, and beds and ancillary services ought to be available for them. A home-hospital must have the same facilities for diagnosis and treatment as a voluntary hospital, and these could only be provided at a capital cost of £1000 per bed. Such a hospital could not be maintained at the present time at a rate of less than 6 guineas a week per patient, and this was not a very high charge for a patient of moderate means provided he was insured; if insurance covered £5 he could pay the rest. A sinking fund was essential to keep the home-hospital in repair and up to date.

Dr. F. J. McCann thought the problem would be best met by building paying departments in connexion with hospitals. He did not think the introduction of pay-beds into the hospitals met the case, because the general practitioner lost his patient under that arrangement. There should be a separate building for the reception of paying patients, but they should have the advantage of the ancillary services of the hospital. He would like to see everyone insured against illness, but unfortunately many people were not insured, and, for these, 7 guineas a week was too much to pay; 5 guineas would be better, but it was impossible to cover expenses at that figure. He did not think pay-blocks could be run unless they shared in the capital resources of the hospital. He saw no objection to this; a great deal was done for the working classes but little for the professional and middle classes.

Dr. G. C. Anderson said that need for pay-beds had arisen owing to (1) the progress of scientific medicine, which had made institutional care necessary in many cases; (2) the domestic difficulties of the middle classes at the present time; and (3) the inability of the patient of moderate means to provide specialist services unaided. If pay-beds were to be provided by some system of insurance it was important that the scheme should allow all members of the medical profession to participate. The idea that it would be impossible to run a hospital if it was open to all practitioners was an old bogy. Not every practitioner wanted to become a surgeon; what he did want was to be able to treat his patient as he would in private and to be able to call in a consultant when he felt inclined. Restrictions about specialist service could easily be laid down. Pay-beds could best be provided in separate blocks attached to voluntary, municipal, or cottage hospitals. Schemes promoted by financiers were looking for too much profit; hospitals were the only bodies which could meet this need.

Dr. H. H. Sanguinetti said that at the National Temperance Hospital general practitioners were allowed to follow their cases into the wards. Voluntary hospitals were, in a sense, endowed for consultants. He would like to see someone endow a hospital where general practitioners could take in their patients and treat them.

Mr. Duncan Fitzwilliams said that insurance societies had a certain vogue, but nothing effective would be done on these lines until a government scheme was enforced by Act of Parliament. A patient earning 3 or 4 guineas a week, who might be in hospital for 10 weeks, could not afford to pay at the rate of 7 guineas a week; but backed by a government insurance service he could face this outlay with equanimity. He agreed that pay-blocks should be built in connexion with voluntary hospitals. If the government took over the care of the destitute, there was no reason why the voluntary hospitals should not help patients of the lower middle class, and he believed that charitably minded people would leave their money for this purpose in the future.

Dr. H. M. Stratford had reason to think that more patients could pay for treatment than chose to do so. The medical profession and the word "charity" seemed to be becoming synonymous. Patients expected to pay the cost of an illness out of income, but they must be prepared to pay for it out of capital. He thought that pay-beds should be provided in a separate institution attached to a voluntary hospital.

Mr. N. G. Loughnane, speaking as a layman, said that the essential factor was the capacity of the patient to pay. It was all very well to say he must pay out of capital, but very few people had any capital to-day. The man with an income of £800 a year and, say, two children, had practically no capital, and any that he had he guarded jealously. He might disgorge £100 for an operation if he was sufficiently frightened, but if there was any doubt he was likely to give the benefit of it to his capital and put off the operation indefinitely. Insurance was only a partial remedy. It was not the expense of nursing which frightened the patient but the expense of the operating surgeon. Mr. Loughnane suggested a fee of 10 guineas a week to include all nursing and treatment. In a hospital of 50 beds this would mean an income of £26,000 per annum. Operations might average four a week, and £5000 could be set aside for the remuneration of the surgeons; the nursing staff would cost £3000, the rent perhaps £1000. He could not see why such a hospital should not be self-supporting.

Dr. G. M. J. Slot said that, in London, nursing-homes were expensive and badly furnished and equipped. On the continent and in America they were well built and properly equipped. At the Mayo Clinic there was a standard charge of 10 per cent. of income for every patient. We should have to look forward to government assistance of patients of moderate means, because it was a government job to see that the health of the public was properly looked after. A charge of 7 guineas a week was too heavy for many people, and yet a barium meal, if it happened to be necessary, cost as much as that to begin with. There was nothing voluntary about the voluntary hospitals, except the services of the medical staff, and they only managed to exist on the sweated labour of nurses. He foresaw a municipalisation of the medical services of London.

Dr. Vaughan Pendred remarked stoically that the extension of various hospital services was bound to reduce the income of the general practitioner; demands upon him were greatly diminished and he must ultimately be extinguished.

The Chairman pointed out that the fees of the surgeon were not excessive considering that he lived for years on his own capital, that his heyday lasted only about 15 years, and that when he was ill his income ceased. He thought that the surgeon's fee frightened the patient unjustifiably; extra charges at the nursing-home were the things he should really fear. He thought that the weekly charge for pay-bed accommodation should be fixed and inclusive.

Mr. SANGSTER SIMMONDS and Dr. GREGG replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND

AT a meeting of the section of obstetrics held on March 2nd, Dr. BETHEL SOLOMONS being in the chair, Dr. O'DONEL BROWNE read notes of a case of severe

Hyperemesis Gravidarum Treated by Jejunostomy

Here the condition was so urgent that immediate treatment was imperative. The patient was 30 years old and seven or eight weeks pregnant. On her first pregnancy she had aborted at the fourth month and some vomiting was present. The vomiting on this, the second pregnancy, had been severe for two and a half weeks before admission to a nursing-home under our care. She presented all the signs of advanced hyperemesis with acidosis, cracked tongue, sordes, and persistent vomit. Constipation was present and relieved by simple enemata. Retroversion of the pregnant uterus was treated and a support inserted. Salines were given, with glucose, by bowel and luminal as sedative treatment. During the first 48 hours treatment the condition disimproved so rapidly, with development of incontinence and restlessness, that fluids were imperatively and urgently needed. Further rectal administration was impossible, a suitable vein could not be found for transfusion, and subcutaneous saline would be too slow to help. Jejunostomy was performed under local anæsthetic. Continuous drip saline through a large rubber catheter into the duodenum commenced and was continued for four days. Glucose 10 per cent. was added and on the fourth day castor oil 2 oz. given by tube. Subsequent to bowel action, whey and other light feeding by tube. The progress of the case was altogether satisfactory. Vomiting ceased within 72 hours; urine excretion and bowel action were established; the jejunostomy closed and the patient sent home within two weeks. Further progress was normal except for premature stillbirth of normally developed fœtus. Large doses of luminal (2 c.cm. repeated three-hourly hypodermically) until restlessness was controlled, was regarded as most important. This, together with the immediate introduction of fluids with glucose, is regarded as the chief factor in the successful treatment of the condition. Jejunostomy is not recommended as routine treatment. It is, however, seen to be of the greatest value in such urgent cases. The opinion is, as regards emptying the uterus, that such treatment is useless in the majority of cases unless either the fœtus be dead or the operation be performed at a very early stage of the disease. In less urgent cases authors favour constant drip salines with glucose intravenously. This is best done by fixation of the leg on a splint and introduction of the fluid by the saphenous vein at the ankle.

Mr. J. OWENS said that when he first saw Dr. Browne's patient he thought the outlook was extremely bad. She was obviously very toxic, and there was acetone in her urine and in her breath. He opened the abdomen under local anæsthesia, through a left rectus incision. The vomit in this case was not examined for glucose. Since operating on this patient he had done two or three jejunostomies and had put in glucose and saline, and had had the vomit examined, and it had always contained glucose. It was possible to get in from 5 to 6 pints of a 5 per cent. glucose and saline solution in 24 hours.

Dr. NINIAN FALKINER referred to a case in which he had introduced glucose intravenously, and in which the response was very satisfactory. The patient was not, however, in such a serious condition as Dr. Browne's. Most cases of severe vomiting in pregnancy that he came across he treated in this way. If patients were seen before dehydration was advanced, the administration of lugol solution was often followed by a good result.

Dr. J. CUNNINGHAM said that these cases of toxic vomiting were very troublesome, especially in hospital practice, and he thought the reason was that they did not go to hospital soon enough. He felt that in teaching there was not sufficient stress laid on the importance of hyperemesis gravidarum. It was sometimes taught that abortion was part of the treatment of this condition. Abortion should not be necessary, and there had never been any indication given by anybody as to when abortion should be induced. If the patient had gone as far as having the liver damaged abortion would not do any good. He personally thought that the injection of corpus luteum and other such drugs was useless in the treatment of hyperemesis gravidarum. Patients required at least 5 pints of water per day, and if possible an effort should be made to give fluid by the bowel. If it could not be given by the bowel, it could be given either intramuscularly or intravenously. He asked if Dr. Browne had tried passing a duodenal tube in this case, and said he thought that having regard to the seriousness of the patient's condition Dr. Browne was quite justified in having a jejunostomy done.

Dr. J. S. QUIN said he thought most of the extreme cases of hyperemesis gravidarum were seen too late by a doctor. By the time they were seen they were usually suffering from a profound degree of dehydration with acidosis which had to be dealt with at once. The degree of toxæmia which was present killed the fœtus. In really severe cases the cause of the hyperemesis was usually not known. It was presumed to be due to a toxæmia, but where the toxæmia came from was not known. It should be borne in mind that vomiting was not a natural concomitant of pregnancy. He asked if Dr. Browne had considered the intensive alkalosis treatment for his patient, and referred to the possibility of some of those cases being due to psychological causes.

Dr. R. M. CORBET referred to the question of getting a tube out of the rectum into the colon, and said he would not try this with a patient who was in such a bad condition as Dr. Browne's patient, because it was a very difficult procedure and took a long time. He thought it could not be done properly without inserting two fingers into the rectum. This led to pulling a patient about a good deal, in some cases more than was justifiable. He had recently removed the corpus luteum of pregnancy from a patient who was six months pregnant, and she had not vomited at all. He had tried treating a case of dysmenorrhœa with nausea with Antuitrin S., and the result was that the bleeding became less, but the nausea and general discomfort became distinctly greater.

Dr. E. A. KEELAN referred to a case of his in which there was great distension associated with vomiting. Jejunostomy was done and the patient made a good recovery. But in a few days she miscarried. He also referred to another case in which there was severe vomiting for four days and intussusception. Jejunostomy was done and the patient recovered. He mentioned the necessity for teaching that vomiting in the early stages of pregnancy might be very dangerous.

The MASTER OF THE ROTUNDA said that cases of excessive vomiting were often found later in pregnancy as well as during the early stages. The pulse was, in his opinion, the real indication of the patient's condition. In one case of his recently there was albumin, and Fouchet's test was positive. She was given saline treatment. Her pulse kept going up slowly. After ten days, labour was induced at 34 weeks and a live baby weighing 4 lb. 3 oz. was born. Immediately after the birth vomiting ceased. He felt that but for induction of labour the patient might have died.

Dr. SOLOMONS said this was the first case of hyperemesis treated by jejunostomy reported from Great Britain and Ireland. In 1919 Prof. T. G. Moorhead had ascribed persistent vomiting after some abdominal operations to vagus shock with motor paralysis of the stomach and over-secretion from the stomach, and suggested when other treatments fail that the establishment of an enterostomy opening high up in the bowel might save some patients: this seemed to be the first published paper dealing with this matter. Sir William Wheeler had made the suggestion to him, but a suitable case had not appeared. To Mr. Owens, who had been Sir William's assistant, great credit was due for the excellent result in the case under discussion. Mr. Victor Bonney had advocated similar treatment for intestinal obstruction, which he believed to be due to spastic contraction of one segment of gut, with disturbance of gas production and gas absorption. Dr. Solomons went on to say that he had himself tried various treatments for hyperemesis; he had not had gratifying results either with intravenous glucose or intensive calcium treatment. He thought it was quite wrong to condemn entirely the evacuation of the uterus. All obstetricians could remember cases which could have been saved if the uterus had been emptied. Death after induction was due to the fact that the induction was carried out too late. There were many cases where the infant was dead, especially about 20 to 24 weeks, where minor Cæsarean section, either vaginal or abdominal, was a life-saving procedure. Induction took too long, and hysterotomy was attended with better results. The way to avoid deaths from hyperemesis was education, but he believed that the mothers of the patients required most education. They told these girls that vomiting was a natural part of pregnancy. In that way the specialist saw the case when it was very far advanced. Students had always been taught that vomiting was pathological. Institutions seemed to vary in their ideas as to what hyperemesis was, for the answer to a questionnaire he had circulated seemed to show that ordinary vomiting was sometimes considered as hyperemesis. He based his nomenclature on excessive vomiting, accompanied by constitutional symptoms and either the presence of albumin in the urine or a positive Fouchet test. Any colonic lavage or prolonged treatment would, in his opinion, have killed this patient.

Dr. BROWNE, in replying, said he had not done a Fouchet's test in this case because it was so urgent. He considered that albuminuria was a very bad sign.

LIVERPOOL MEDICAL INSTITUTION

AT a pathological meeting of this institution on March 22nd, with Dr. J. MURRAY BLIGH, the president, in the chair, a paper on some problems and investigations in the

Pathology of Fat Metabolism

was read by Prof. J. HENRY DIBLE, who described work he had carried out during the past few years. Fatty change, he said, was one of the conditions most often encountered in certain organs, particularly the liver, at post-mortem examination. It was frequently seen in wasting diseases such as infantile summer diarrhœa, and this apparent anomaly could be explained if the changes which occurred in the liver fat in starvation were understood. Experiments had shown that starvation caused a notable accretion of fat to the liver, but that the amounts were very variable and independent of the length of the starvation process. Careful quantitative investigations had shown that under similar conditions the quantity of fat infiltrating the liver in starvation was determined by the quantity of fat available in the animal's storage depôts. These results had been obtained in the first instance in the rat, but he and Dr. J. Libman had found them to apply also to the rabbit. Since in most illnesses there was an element of starvation in the terminal stages, it might well be that this was a major factor in inducing the common fatty degeneration, equally with poisons or anoxæmia. This question had been investigated with the help of Dr. W. W. Gerrard, and a definite relationship had been established, in man, between the quantity of fat appearing in the liver and the degree of inanition before death. In such cases a relationship had also been established between the degree of fatty infiltration and the adiposity of the subject. Turning to the question of fatty degeneration of the heart, Prof. Dible pointed out that in experiments carried out with Dr. Gerrard on phosphorus poisoning, a quantitative increase of fat in the degenerated cardiac muscle was constantly demonstrable. In work he had carried out upon the human heart in disease the same held good, very large increases being sometimes demonstrable and some increase, related to the histological picture, being constant. From a discussion of the histological changes in heart and liver showing fatty degeneration he reached the general conclusion that in both organs fatty change was of the nature of an infiltration, there being no evidence for the existence of the process usually called phanerosis.

MANCHESTER MEDICAL SOCIETY

THIS society held a joint meeting with the Liverpool Medical Institution at Manchester on March 7th. Dr. C. PAGET LAPAGE, the president, took the chair, and a paper on

Cerebral Pneumography

was read by Dr. HENRY COHEN. The method, he said, was based on two principles: (1) that no gross lesion can exist in the brain without deforming the fluid-containing spaces, with resultant changes in their size, shape, position, and communication; and (2) that it is possible to replace the cerebro-spinal fluid by air, by either the lumbar route (encephalography) or the ventricular route (ventriculography) and thus visualise accurately by radiography the normal or deformed fluid spaces. He described in detail the methods he employed in both encephalography and ventriculography and emphasised that the most notable contra-indication to encephalography was the suspicion of a subtentorial tumour. Ventriculography was necessary to define the ventricular system, however, if any obstruction to the passage of air from the subarachnoid space to the ventricles was present. In only a quarter of "tumour suspects" was cerebral pneumography required; occasionally it was useful to differentiate vascular lesions and degenerative processes from expanding lesions, but more often it was needed to help in the localisation of tumours which showed no localising signs or had given rise to false localising signs. Pneumography must always be subordinated to clinical examination, but it was helpful in practice and had thrown light upon the pathological basis of some of the epilepsies and traumatic "neuroses."

Immobilisation of Fractures

Mr. R. WATSON JONES (Liverpool) read a paper on Inadequate Immobilisation and Non-Union of Fractures. He believed that recent enthusiasm for early mobilisation and functional activity in fracture treatment was entirely justified, in that incapacity periods were reduced and many permanent disabilities avoided; but it should be recognised that joint mobilisation must not interfere with complete and uninterrupted immobilisation of the fracture. There was no more constant cause of non-union than inadequate immobilisation. Hyperæmia of bone caused decalcification, and if the initial hyperæmia of the trauma of injury was perpetuated by the frequently repeated trauma of movement of the fragments on each other, decalcification continued until a crack became a cavity, and a linear fracture became a gap fracture.

Even slight movement, and especially rotatory movement, was sufficient to account for excessive decalcification. The Whitman plaster for fracture of the neck of the femur did not as a rule prevent rotatory movement of the pelvis and head of the femur, and for this reason even in the 50 per cent. of cases in which union took place under this treatment, there was usually evidence of excessive decalcification in the shortening of the neck of the femur. On the other hand a Smith-Petersen nail completely prevented rotatory movement, and in the speaker's series of 28 subcapital fractures treated by operation, over 90 per cent. had united. In fractures of the lower shaft of the ulna, non-union was due to attempted restoration of radio-ulnar movement after six or eight weeks of immobilisation, before the fracture was consolidated. The radio-ulnar joint had become stiff so that the movement could occur just as easily at the unconsolidated fracture as at the stiffened joint. For this reason, in three years Mr. Watson Jones had seen 18 ununited fractures of the lower shaft of the ulna, although in every case the associated fracture of the radius—which was not subject to rotatory strain—had united. If these fractures were completely immobilised for the three or four months which were necessary to show radiographic evidence of consolidation, non-union never occurred. Fractures of the scaphoid bone in the wrist illustrated the same principle. Recent fractures usually united in six to eight weeks, but sometimes it was necessary to continue immobilisation for many months, and if the institution of treatment was delayed, twelve to eighteen months of absolute immobility might prove necessary. If the surgeon was prepared to wait for it, bony union could be secured in almost every case. The speaker's conclusion was, that whatever other factors might affect the union of fractures non-union was seen only if immobilisation was incomplete, or if it was not continued for a sufficient period.

REVIEWS AND NOTICES OF BOOKS

Legal Aspects of Mental Illness

Third edition. By WM. H. GATTIE, Barrister-at-Law. London: Shaw and Sons. 1933. Pp. 86. 7s. 6d.

WHEN Section 20 of the Mental Treatment Act substituted its sensible if copious euphemisms for the word "lunatic" in enactments and other official documents, nothing was said as to the word "lunacy." The Lord Chancellor still makes Rules in Lunacy, and the judges still speak of lunacy jurisdiction. Mr. Gattie, in his new edition of what used to be entitled "Lunacy Practice, Certification and Detention," acts in the spirit of Section 20 and entitles the book "Legal Aspects of Mental Illness." Having now to deal with the voluntary and temporary treatment introduced by the 1930 Act, the new edition is naturally of wider scope than its predecessors. There is also a new chapter on testamentary capacity. Here he suggests that the medical attendant, when satisfied that the patient is of sound disposing mind, should himself act as one of the witnesses to the will if the capacity is likely to be challenged. In this connexion the Christie litigation of a few years ago will be remembered.

Mr. Gattie's chapters are short and to the point. Forms, filled up as specimens, take up most of his space. He criticises the drafting of Section 5 of the 1930 Act wherein a temporary patient is described as one "who is suffering from mental illness and is likely to benefit by temporary treatment but is for the time being incapable of expressing himself as willing or unwilling to receive such treatment." In practice, he says, these words cover (1) persons so confused as to be incapable of expressing themselves by a simple affirmative or negative as willing or unwilling to receive treatment, and (2) persons totally devoid of the capacity to appreciate the meaning of submission to treatment. With such a construction, he adds, the section can be used only for a small percentage of cases; he would like to have seen a definition of "capable" and "incapable" in the Act if this restricted interpretation was intended. The obscurity is regrettable, but the draftsman could hardly have given a highly technical meaning to such simple words. The result perhaps places the more power in the hands of the medical experts who have to apply the phrase. The Royal Commission, on whose report the Act was based, distinguished two categories of mental disorder, the voluntary and the involuntary patients. The provision for voluntary boarders was to be limited to those who had volition, but the Royal Commission excused itself from defining the degree of volition to be attributed to persons who *ex hypothesi* are in a morbid state. The report described the involuntary patient as one "who is either without volition or is resistant and whose liberty must be infringed in order that he may be properly controlled and treated." For involuntary patients the Commission proposed two alternatives: (*a*) a provisional treatment order where there was a prognosis of early recovery, and (*b*) a reception order on full certification in other cases. What matters now, however, is what Parliament enacted, not what the Commission recommended. Mr. Gattie is a writer of authority on the legal aspects of this subject, and his little book will be found a useful work of reference.

Neuroanatomy

A Guide for the Study of the Form and Internal Structure of the Brain and Spinal Cord. Sixth edition. By J. H. Globus, B.S., M.D., Associate Professor of Neuropathology and Neuroanatomy, New York University and Bellevue Hospital Medical College. London: Baillière, Tindall and Cox. 1934. Pp. 240. 16*s*.

The popularity of this handbook is probably due to the original method by which it sets out to teach a subject generally regarded as difficult both by student and demonstrator. It is divided into two parts. The first is the text, which gives a concise description, illustrated by a number of good drawings and photographs, of the fundamental anatomy of the central nervous system. This description is interspersed with directions both for carrying out the dissections and for using to best advantage the second part of the work. This part consists of 53 plates on dull paper of serviceable opacity, forming an atlas of line drawings depicting different aspects of the brain, and sections at different planes and levels. It is intended that the student should complete these from his own observations. In a few examples the drawings are complete, and the student is invited to label the different structures shown. This is a great help to those who cannot draw and a saving of time to those who can. It would be difficult to imagine a pleasanter way of grappling with this particular branch of anatomy; anyone who conscientiously goes through the exercises provided in this book will almost certainly acquire a good working knowledge of the structure of the brain and spinal cord.

The Biology of the Protozoa

Second edition. By Gary N. Calkins, Ph.D., Sc.D., Professor of Protozoology, Columbia University. London: Baillière, Tindall and Cox. 1933. Pp. 607. 37*s*. 6*d*.

Most recent books on the protozoa have been written by protozoologists chiefly interested in parasitic or disease-producing forms. Dr. Calkins has devoted himself especially to the study of free-living protozoa, and this from the point of view of fundamental organisation and behaviour rather than that of details of structure and life-history. It is thus not surprising that his book deals primarily with biological phenomena as exemplified by the protozoa. Among the many subjects considered fully in the light of modern knowledge are cell-division, reproduction, fertilisation, sex differentiation, growth, vitality, maturity, senescence, and reorganisation. Naturally the author's own views, formed as a result of years of investigation, occupy a prominent position. Readers will be particularly grateful to him for this restatement of his convictions. Parasitic protozoa, more especially those injurious to man, are briefly considered in a chapter devoted to ecology, commensalism, and parasitism. This will form a useful summary for the general reader of what is known of these organisms, though a few slips and omissions here and there indicate that in this section the author is on comparatively unfamiliar ground. The last four chapters of the book are devoted to the special morphology and taxonomy of the four main subdivisions of the protozoa. These appeared in the earlier edition in the middle of the work, and their change of place is a distinct improvement. In each of the four chapters is included a key to the classification of the genera belonging to the group considered, which will continue to be of great use to protozoologists as a means of identifying genera.

Those who wish to understand the general principles underlying the science of protozoology and something of the complex organisation, development, and reproduction of unicellular animals and the laws which govern these processes cannot do better than read this book; it is well illustrated, and is a valuable contribution to the literature of the subject.

The Pocket Anatomy

Ninth edition. By C. H. Fagge, M.B., M.S., F.R.C.S. London: Baillière, Tindall and Cox. 1933. Pp. 333. 5*s*.

This thoroughly reliable little book will be as useful to students now as it was to their predecessors. The great change in this edition is the use of the "English" terminology, recently adopted by the Anatomical Society; this is the first general work to appear with this nomenclature. It is pleasant to be able to say that the first encounter leaves a favourable impression on the mind; not only are the terms sensible and applicable, but the language runs with more vitality and less restraint than when the terminology hitherto in common use was used. The change-over of this small classic to a language which appears worthy of general English adoption is a noteworthy departure, which will, we believe, be generally welcomed.

Metabolic Diseases and their Treatment

By Dr. Erich Grafe, Professor of Medicine and Director of University Clinic of Medicine and Neurology, Würzburg, Germany. Translated by Margaret Boise. London: Henry Kimpton. 1934. Pp. 539. 32*s*.

This book is translated from the first German edition and is probably the first substantial book in the English language dealing exclusively with metabolic diseases. An extensive bibliography is supplied and is conveniently arranged; the references are mostly to German work. After a few introductory remarks on general metabolism, the general functions of proteins, carbohydrates, fats, and vitamins are discussed, but hardly in sufficient detail. The metabolism and treatment of under- and over-nutrition is next considered; the section on obesity is prolix and rather vague. It is disappointing, in the discussion of the mechanism of fever production, to find no mention of W. Cramer's valuable theory of the importance of the thyro-adrenal mechanism.

About half the book is devoted to diabetes; the reason given for this allocation of space is that its therapy has now been successfully placed on a sure basis. The practical instructions for treatment here supplied, however, are of little help, although the underlying metabolic principles are adequately exposed and discussed. In this section also the references are overwhelmingly to German literature, though it is generally recognised that the main recent advances in both physiology and therapy have been published in the English language. This defect shows up glaringly in the pages of an English translation. Gout is dealt with in considerable detail and all the anomalies of metabolism are touched on, such as alcaptonuria, cystinuria, and so forth. A useful section on the "calcareous diatheses" is appended.

There are few serious omissions in the book, but a section on metabolic œdemas should have been included, and hæmochromatosis not have been dismissed in five lines. The task of compiling a comprehensive volume on metabolic diseases is probably an impossible one; the subject is too wide for one person to have a deep and critical knowledge of more than a small part of it. We trust that this book will stimulate the production of a more useful symposium; in its present form it is too large to be a primer, and too small to be a satisfactory work of reference. All the same, Dr. Grafe has rendered a considerable service to workers in this field by including in one volume a consideration of all metabolic diseases, which have so far usually been dealt with in separate monographs or reviews. The translation as a whole is seldom obscure in meaning, though many phrases used will sound strange to the English reader. The same cannot be said for the first introductory page, which is not English and hardly intelligible.

1. The 1933 Year Book of General Surgery

Edited by EVARTS A. GRAHAM, A.B., M.D., Professor of Surgery, Washington University School of Medicine. Chicago: Year Book Publishers. Pp. 826. 13*s.* 6*d.*

2. The 1933 Year Book of Urology

By JOHN H. CUNNINGHAM, M.D. Same Publishers. Pp. 445. 10*s.* 6*d.*

1. THIS volume, published quite early in the New Year, provides an excellent review of the contributions made to general surgery during 1933. It will prove of value not only to the surgeon who has been unable to keep up with current literature, but also to those who have noted advances but failed to remember the sources of their knowledge. The work owes much to the sound critical sense of its editor, who deserves credit for its timely appearance.

2. In his preface the editor draws from the literature of the year the conclusion that the urologist is now thinking and working in terms of broader understanding. Articles on certain features of biophysics and biochemistry, systemic infection, and changes in the central nervous system all indicate that urologists are realising more fully the necessity of avoiding watertight compartments, and of finding a correlation between diseases of the genito-urinary system and those of other parts of the body. A vast field of literature has been sifted and the editor has shown skill in epitomising that which is of value.

The Progress of Science

By J. G. CROWTHER. London: Kegan Paul, Trench, Trübner and Co. 1933. Pp. 304, 11 plates. 12*s.* 6*d.*

ABOUT a couple of years ago Mr. Crowther had the audacity to attempt a description of the universe in one volume—and not a very big one at that. He brought off a brilliant success of learning and exposition, and his new book deserves an equally warm welcome from those who like to know what is going on in scientific investigation. Six of the nine chapters are physical; they deal with heavy hydrogen, atomic constitution, research in Russia, the stars, and include a particularly attractive account of cosmic rays. That headed the Chemistry of Evolution comes largely from Needham's monumental book; the modern knowledge of plant pigments, the differentiation of embryos, and the molecular structure of organic substances are also described. Human Heredity is a salutary statement of what little we know. The final chapter gives a rather mediocre account of pernicious anæmia. Throughout the author emphasises the dependence of scientific progress on personality, and he points out its relation to social conditions with shrewd observations of much more than technical interest.

Virus Diseases of Plants

By JOHN GRAINGER, Ph.D., B.Sc. London: Humphrey Milford, Oxford University Press. 1934. Pp. 104. 6*s.*

THIS book is intended to serve as an introduction to the subject of plant viruses. Following a brief historical introduction, Dr. Grainger describes the symptomatology of these diseases, their pathology, mode of transmission, immunity, and so forth. Subsequent chapters deal with the properties of these viruses, insect transmission, economic effects, and measures of control and classification. The last chapter provides a general account of experimental work. All this is clearly and simply described, with a certain amount of technical detail, and some good illustrations. The term "virosis" is not a pleasing one, and "viroses" even less so. A mistake occurs on p. 31 in the recommendation to boil the filter in strong *caustic* soda after use. A list of over 400 references adds to the value of this useful little book, which has an adequate index.

REPORTS AND ANALYSES

ARISTON YAGHOURT

(ARISTON YAGHOURT CO., LTD., 19, STREATHAM HILL, LONDON, S.W.)

THE examination was confined to ascertaining the bacterial content of this material, which is a sour milk preparation for which various therapeutic advantages are claimed. *Direct films* show large numbers of gram-positive bacteria in two forms, large ovoid coccal bodies in pairs and short chains, and long stout curved rods. It is evident from cultural results that these are two forms of the same micro-organism.

CULTURES

(*a*) *Quantitative.*—Shake cultures in glucose agar made from a series of decimal dilutions and incubated at 37° C. indicate a living bacterial content of 290,000,000 per c.cm. Similarly made cultures in gelatin incubated at 22° C. yield no growth.

(*b*) *Qualitative.*—Surface-sown plates of glucose agar and litmus lactose agar incubated anaerobically yield a pure growth of a Lactobacillus; by its morphology, the failure of growth on agar, and its fermentation of maltose, this micro-organism is identifiable as *L. acidophilus.* It acidifies litmus milk in 24 hours, and subsequently produces the typical decolorisation of the lower part of the tube.

The keeping qualities of the material were investigated by making a further series of quantitative cultures nine days after receiving the sample. A growth of *L. acidophilus* in milk was obtained from quantities down to 1/100,000,000th of a c.cm., indicating that at least a large proportion of the bacilli had survived for that period.

CONCLUSIONS

The specimen of "Ariston Yaghourt" received is a pure culture of *Lactobacillus acidophilus.* In as far as milk soured by this micro-organism can be of service as a therapeutic agent, this preparation should satisfactorily fulfil the purposes concerned.

"HEPOL" Liver Products

For the treatment of Pernicious Anæmia, etc.

"Hepol" liver extract enables physicians to administer in a concentrated, tasteless, and convenient form the principle that is effective in pernicious anæmia. This extract is available in the form of capsules, powder, and liquid, which, being quite palatable and easily swallowed, will be found highly advantageous in cases in which the taste of liver proves objectionable. Each batch is standardized by carefully controlled tests on cases of pernicious anæmia.

Experiments on rats have shown that "Hepol" liver extract is rich in vitamin B_2

"Hepol" Dry (equal in strength to the B.P. dry extract)		
Each tube=8 oz. of fresh liver	Box of 12 tubes	25/-
"Hepol" Dry, ½ size	Box of 12 tubes	12/6
Each tube=4 oz. of fresh liver.		
"Hepol" Liquid (equal in strength to the B.P. liquid extract but with attractive flavouring)		
1 oz.=8 oz. of fresh liver.	Bottle of 4 oz.	6/-
	,, 8 oz.	11/6
	,, 16 oz.	22/-
"Hepol" Elixir	Bottle of 4 oz.	4/-
1 oz.=4 oz. of fresh liver.	,, 8 oz.	7/6
	,, 16 oz.	14/6
"Hepol" Capsules	Tube of 8	2/6
1 capsule=1 oz. of fresh liver.	Box of 6 tubes	12/6
	12 ,,	24/-
"Hepol" Capsules (⅓ strength)... ...	Box of 20	2/-
1 capsule=⅓ oz. of fresh liver.	,, 40	3/9
	,, 80	7/-
"Hepol" Sterilized Solution (for parenteral injection).		
2 mils=40 gm. of fresh liver.		
	2 mil ampoules, box of 3	3/6
	,, 6	6/6
	5 mil ,, ,, 3	7/6
	,, 6	14/-
"Byno Hepol" ("Hepol" with "Bynin" Liquid Malt)		
3 tablespoonfuls=8 oz. of fresh liver.	Bottle of 4 oz.	6/6
	,, 10 oz.	15/-
"Hepol" L.Y.H. (Liver, Yeast, and Hæmoglobin)		
1 oz.=4 oz. of fresh liver and 40 grains of dried yeast.	Bottle of 4 oz.	4/6
	,, 8 oz.	8/6
	,, 16 oz.	16/6
"Hepol" Elixir with Iron		
1 oz.=4 oz. of fresh liver and 30. grains of iron and ammonium citrate.	Bottle of 4 oz.	4/-
	,, 8 oz.	7/6
	,, 16 oz.	14/6

Descriptive literature will be sent on application.

Telegrams—BELLEVUE, TREFRIW.

Literature, with illustrations, will be sent to members of the Medical Profession who are interested in the Ambulatory Treatment and Manipulation with Extension for Diseased Joints, which for many years I have carried out in London and at Bellevue Spa, Trefriw, North Wales.

Medical practitioners are quite rightly hesitant in adopting methods of treatment which seem to run counter to the principles in which they have been trained. They have always been taught that it is dangerous to manipulate a diseased joint for fear of starting fresh mischief. As a result numbers of patients have been left permanently and completely crippled owing to fixation of joints by tuberculous or various forms of arthritic disease.

No harm results from manipulation of a diseased joint, provided that the surfaces are kept separated during the manipulation, and afterwards, for a long period. This is effected by the special extension table devised by the writer and subsequently by his extension appliance. Patients thus have their diseased hips or knees straightened and are enabled to walk about and lead active lives, whilst the joint surfaces, kept free from *all irritation*, undergo a process of regeneration, until eventually the splint can be discarded and the former hopeless cripple becomes a normal member of society.*

It is a great advantage to the patient that the earlier stages of this treatment may be carried out under the supervision of a qualified medical man in the quiet and health-giving surroundings of Trefriw, in an establishment which combines the advantages of a well-equipped nursing home with the amenities of a high-class hotel.

In addition, attention is directed to the advantages of the chalybeate water available at the Bellevue Spa, which enables anæmic patients to undergo a course of a strong iron tonic in a particularly pleasant and peaceful environment. Massage, electrical treatment, and baths of the most up-to-date character are also provided in a completely equipped building adjacent to the Hotel. Tonic iron water and suitable local treatment, together with pure mountain air, provide an ideal combination for many cases of rheumatic disease.

Any further information will gladly be supplied by

Yours faithfully,

CAREL A. HOEFFTCKE

British Made by

T. J. SMITH & NEPHEW, LTD.

Dept. L.E., *Neptune Street*, HULL.

Manufacturers of Paragon Brand Surgical Dressings

This comprises crosswise elastic cloth spread with the Elastoplast Zinc Oxide adhesive surface.

The Elastoplast Extension Bandage possesses the lengthwise rigidity for reduction, whilst it may be stretched and moulded to the contours of the limb.

Its suppleness obviates irritation, no sores form, and it is more comfortable and reliable than any other type of plaster.

2½-in., 3-in. and 6-in. widths, unstretched, supplied in 1-yard containers.

Samples gladly sent on request.

INFECTIOUS DISEASES AND THE BRAIN

It sometimes happens in science, and especially in medical science, that what has been regarded as an axiom turns out to have been a hasty generalisation. For example, it has long been assumed that the symptoms characteristic of all fevers—such as apathy, insomnia, raised temperature, metabolic disturbances, vasomotor collapse, and eventually death—are due to disturbances of the brain centres produced directly by bacterial toxins. Prof. Friedemann and Dr. Elkeles, in the paper concluded in our present issue, throw doubt on the validity of this assumption.

Whether bacterial toxins do or do not act on the nerve-cells of the brain must obviously depend in the first place on whether they are able to reach these cells, although other factors such as chemical affinity will play a secondary part. The problem is bound up, therefore, with the problem of the exchange of substances between blood and brain. The work of the last few years has shown that this exchange is regulated by a selective mechanism, described by continental writers as the "barrière hémato-encéphalique" or "Bluthirnschranke," or in English as the "blood-brain barrier," or B.B.B. In the brain, as in other organs, the selective mechanism is localised in the walls of the capillaries; in this case it is in the cerebral capillaries, and not, as was formerly thought, in the choroid plexus and the meningeal vessels. Friedemann and Elkeles have devised new methods of testing the permeability of this barrier for various toxins, and their results show clearly that the toxins differ among themselves in the facility with which they pass through it. Those of the botulinus, diphtheria, and tetanus organisms, for instance, do not pass the blood-brain barrier at all (tetanus is, of course, exceptional in reaching the brain by another route, through the peripheral nerves). On the other hand, there are some, such as lamb-dysentery toxins and cobra venom, which definitely do go through the barrier. The two groups differ also in another respect: those that are able to pass the B.B.B. produce their lethal effect rapidly, whereas those that cannot pass the B.B.B. require a period of incubation. If this tentative generalisation should be found to hold good for all toxins, it will mean that few bacterial toxins act on the brain; for we know that most of them require a period of incubation. On further inquiry into the property of the toxins which govern their ability to pass the blood-brain barrier, it was found that those that could not pass the barrier carry a negative charge, while those that could pass it are either neutral or positively charged. It follows from this that differences in the length of the incubation period characteristic of different toxins depend on their electrical charge.

The subject is highly technical and may at first sight seem somewhat remote from practice. Prof. Friedemann, however, is not only a laboratory worker but also a clinical authority on the treatment of infectious diseases, and his investigation has clearly arisen as an attempt to account for the clinical features of these diseases and also for failures in their treatment. The handling of diphtheria, for example, is to some extent based on the assumption that the toxin has a direct localised action on the brain and also on the heart muscle, and Friedemann's treatment of it has been profoundly influenced by the results of his laboratory studies. Since vasomotor collapse, which is an outstanding feature of diphtheria, has been ascribed in the past to a paralysis of the vasomotor centre, it has been treated by drugs expected to stimulate the centre; though Friedemann says he has never seen any good come from such remedies. But if diphtheria toxin does not reach the brain, the vasomotor collapse must be of peripheral origin and must be treated accordingly. With this in view he instituted in Berlin its management by means of hot baths, and he claims that "the effects of this treatment are striking even in the most severe cases, and not to be compared with those of drugs. Symptoms are improved at once and remain so for hours." According to his new conception of the pathogenesis of infectious diseases the toxins of many other infections should produce their effects peripherally and not centrally, and it may be expected that a better understanding of their action will lead to further improvement in their treatment. The Medical Research Council is to be congratulated on having enabled Prof. Friedemann to continue his work by providing him with laboratory facilities in London.

A GENERAL MEDICAL SERVICE

The official report of the annual meeting in Llandudno last September of the National Conference of Friendly Societies contains a scheme for a general medical service submitted by its executive committee. The services proposed were comprehensive, covering treatment by a family doctor, medicines, nursing in the home, provision of consultants, specialists and auxiliary means of diagnosis (presumably pathological) through the general practitioner, home hospitals in which general practitioners would treat their own patients and meet one another in friendly consultation, residential accommodation in hospitals, sanatoria, and convalescent homes, and such other medical and allied services as may from time to time be arranged. In addition to insured persons as defined in the National Health Insurance Acts, persons who would be insured but for the fact that they are following excepted employments would become compulsory contributors, and voluntary participation would be extended to all members of friendly societies. Further, dependants of all such persons would be brought into the scheme and an arrangement would be made with county and county borough councils to delegate their obligation to afford medical assistance to the poor to the enlarged insurance medical service. Some arrangement for a maternity service and the incorporation of the present dental and ophthalmic provision would be made as soon as possible.

The proposals so far, it will be observed, agree generally with those made in 1930 by the British Medical Association.[1] On the administrative side, however, there is a definite divergence of view. The B.M.A. favours a complete coördination of domiciliary and consultant practice, laboratories, hospital and nursing provision with the existing official services of a medical character, under the control of a statutory committee set up by county and county borough councils, to be known as the "Medical Services and Hospitals Committee" and composed of representatives not only of the present health, education, mental hospitals, mental deficiency, and public assistance committees of these councils, but also of bodies of persons rendering service under the scheme. The administrative officer would be the medical officer of health, and there would be central and local consultative medical committees. The conference of Friendly Societies does not subscribe to these suggestions. Its scheme adumbrates a sharp division between what is called a "health service" directed to the prevention of disease and a "therapeutic service" devoted to the relief of individuals. Although it is not specifically said, it would appear to be implied that the latter would include some of the clinical services now administered by local authorities, including domiciliary public assistance of a medical kind and hospital treatment, whether provided under the Public Health Acts or the Poor Law. This comprehensive therapeutic service is to be administered by "ad-hoc local authorities comprising representatives of bodies or authorities through which contributions are received and of organised bodies of persons supplying services"; in other words an authority after the fashion of the present local insurance committees.

There can be little difference of opinion as to which of these schemes is more in line with the evolution of British local government, nor, indeed, as to which would be more acceptable to the medical profession. It is obvious, however, that continuance of the collection of insurance contributions, and of the administration of financial benefits through friendly societies and insurance companies, must be accompanied by a demand for a voice in the control of the management of any medical service which is part of an insurance scheme. In this connexion, the cost of extensions of the kind proposed was rather casually mentioned in the conference at little more than £11,000,000, the sum tentatively put forward by the Royal Commission on National Insurance in 1926. It seems to have been overlooked that that figure did *not* include the cost of any hospital service, and that no country has yet succeeded in bringing such a service within a self-contained and solvent general insurance scheme. Inclusion of hospital treatment would probably entail such large subventions from the present responsible authorities, the county and county borough councils, as to raise a demand from them for an overwhelming representation on any ad-hoc administrative bodies, which would leave them little different in constitution from committees of these councils.

The conference of Friendly Societies adopted its committee's scheme unanimously, and evidently contemplates early negotiation with the B.M.A. and bodies representative of county and municipal authorities and insurance committees. In the meantime, the need for extension of a general practitioner service to dependants is being rapidly, if partly, met by the development of public medical service schemes organised by practitioners themselves. Consultant services might also by this time have been widespread outside of London, where one such scheme is working, but for the fact that consultants have looked upon them with suspicion. It might be well for them to realise that while they are hesitating they may find themselves faced with proposals to which they have no ready alternative.

THE GALL-BLADDER AND CARDIAC PAIN

> "The heart and the gall-bladder are each capable of producing devastating and demoralising pain. Their innervation is from neighbouring regions of the central nervous system. It would be surprising if the symptoms were always so clear-cut that they could be given their true significance. Many practitioners have had cases which have perplexed them as to whether they were dealing with a cardiac or a gall-bladder disorder."

THIS quotation from a paper by Dr. CHARLES MILLER[1] sets out the main elements of an important problem which has been much discussed. Many cases have now been recorded in which attacks of pain might fairly have been described as cardiac or anginal in origin, but were permanently banished by removal of the gall-bladder. This has led some authorities to believe that disease in the gall-bladder may be the direct cause of disease in the heart. For example, in the correspondence which arose on Dr. MILLER's paper, Lord MOYNIHAN stated that where heart disease is given as the reason for not operating for gall-stones, a subsequent cholecystectomy is commonly followed by restitution of the heart to normal or by considerable relief of cardiac symptoms. Disease of the myocardium, he said, may often be regarded as the strongest indication for surgical measures. Again, it is not a rarity to find an attack of cardiac arrhythmia associated with what clinically seems to be an attack of cholecystitis, and in a later letter Dr. MALCOLM STALKER described a case in which biliary colic seemed directly responsible for a paroxysm of complete arrhythmia. JAMES MACKENZIE,[2] who was fully aware of these difficulties, maintained that the condition most often mistaken for angina was colic arising from the gall-ducts or the gall-bladder, and in illustration quoted JOHN HUNTER's illness, suggesting that the pain HUNTER had 17 years before his death was due to gall-stones and differed widely in character from what he suffered eleven years later. This view was supported when an examination of Hunter's body revealed both coronary artery disease and gall-stones.

[1] THE LANCET, 1932, i., 769.

[2] Angina Pectoris, London, 1923.

Many other authorities have expressed their belief that disease of the biliary tract is a common cause of cardiac disease—among them, in England, H. D. Rolleston and Osler. In the United States R. H. Babcock reports having seen many cases in which operation has proved that cardiac disorder was immediately secondary to a chronic or acute cholecystitis; and similar opinions are held by M. J. Lichty and Bayard Holmes. Recently A. P. and R. N. Klemmer[3] have studied a series of 69 cases showing various degrees of associated cardiac and biliary tract disease. In 21 of these the heart was so far damaged that operation was undesirable, but when the patients were treated by non-surgical biliary drainage—and rest—there was much improvement in the cardiac condition. E. Doumer[4] distinguishes two types of case: in the first there is indefinite but alarming malaise associated with paroxysmal arrhythmias set up by reflex irritation from the gall-bladder; in the second there are attacks identical with true angina. Referring to the first type he points out that though extrasystoles are of no cardiac significance they may be produced by reflex irritation from an inflamed gall-bladder and in more or less prolonged attacks may give the sensations of palpitations, accompanied not so much by pain as by a sensation of great anxiety —"a sensation of profound, indefinable, and menacing malaise"—with a fear of impending death and a feeling of oppression in the chest. This last symptom may well mislead the physician into a diagnosis of true angina but careful interrogation should prevent the error. The second type, in which cholecystitis gives rise to a syndrome identical with angina of cardio-arterial origin without any associated arrhythmia, is much more difficult. The existence of such cases can hardly be doubted, Prof. Doumer thinks, since many convincing observations are on record. During the attack, he adds, correct diagnosis is almost impossible, but the electrocardiogram—although not infallible, since altered complexes need not be present—will often reveal the truth when the results of clinical and X ray examination are indefinite.

We may end, as we began, with a quotation from Dr. Miller. "Is it possible," he asks, "for a diseased gall-bladder to produce symptoms that would be agreed to be cardiac? This question cannot be answered dogmatically, but it is possible that disease of the gall-bladder can produce the same shock and symptoms similar in type, localisation, and severity as disease of the heart. . . . Cases occur in which the symptoms are cardiac, and later a gall-bladder attack supervenes which calls for operation. After the operation the cardiac symptoms disappear. We cannot be certain, we can only speculate about such cases."

THE DROUGHT CONTINUES

The Easter vacation seems to have satisfied the Minister of Health of the urgency of the need to safeguard water-supplies, for his first act after the recess was to present a Bill to give local authorities power to act promptly. The Bill does not increase the grant of a million pounds provided by the Rural Water Supplies Act which received Royal assent on March 28th; but it makes it possible to apply this grant with more immediate effect. The situation is without parallel in our time, although most of the questions at issue arose in the great drought of 1921–22, when the use of waste water and of compensation water, the pooling of water interests, the question of central control, of rights to underground water, of standard rates of domestic consumption, of adequacy of future reserves and of utilisation of abandoned sources of water-supply were all actively canvassed. Many waterworks authorities were then forced to take cognisance of a wide variety of factors which previously had not invaded their horizon. More remarkable still, an atmosphere of trust was created between water authorities and consumers which had never existed before to the same extent. That drought left us a little better equipped for the future, but pity of it that the fear of scarcity was allayed too soon for much practical result.

The situation to-day is far more serious than it was 12 years ago, although it is hardly likely to hit the urban dweller further than to limit waste and luxury. A circular issued to owners and occupiers of premises within the area of the Metropolitan Water Board has asked them to be careful of leaking taps and unattended hose-pipes. "Use water but do not waste it" is the keynote of its message; but in rural England it will require a careful consideration of local needs and conditions if there is to be any water to use. In his circular of April 6th the Minister has asked every water authority for an outline scheme of development. In some cases it may be a stand-pipe supply that is most urgently needed; in others the provision of a good well or the development of a spring, or the means for collection and storing of rain-water. A piped supply may not be practicable because of its cost, and it might be worse than useless unless sewage disposal were provided at the same time. The grant will not be given unless consumers are willing to pay proper charges for their water, and it will come as a surprise to a community that has regarded water as a priceless gift from the skies to be told that the Minister considers 3*d.* a week not excessive for supplying a cottage rated at £5 a year. But the local authority will be given a wide range in its search for water, with the choice of contracting with an adjoining authority which has more than it needs; or with a landowner or water company able to provide; or through a new development of local sources by combining with neighbouring parishes or rural districts. The present situation offers ample scope for bold and wise local statesmanship.

ANNOTATIONS

CENTENARY OF THE ROYAL STATISTICAL SOCIETY

ON April 17th the Royal Statistical Society will celebrate its hundredth birthday. In the afternoon the Prince of Wales, hon. president of the Society, will preside over the Centenary meeting, and in the evening Lord Meston, president, will take the chair at a centenary banquet. The International Statistical Institute, which was founded at the time of the Society's jubilee, is holding its biennial session in London, so that the meetings will be attended by distinguished statisticians from all parts of the world. The founders of the *Statistical Society of London* (the style was changed to Royal Statistical Society after the jubilee) were men of insatiable curiosity; the first volume of the *Journal* (now in its ninety-seventh volume) provides information respecting the numbers of bibles in houses of working people, the number and proportion of perpetrators of burglaries escaping, the number of fourpenny pieces issued in 1836–38, the dislike of the French by the New Zealanders, experiments with manure in Northumberland, and much, very much, besides.

Primarily the founders were interested in social phenomena, and so it is not surprising that, from the first, medical topics occupied a good deal of attention. The first volume contains a detailed study of the sickness and mortality among the troops in the West Indies, by Colonel A. M. Tulloch, and in the fourth volume the name of the greatest of medical statisticians, William Farr, appears as the author of a paper on the mortality of lunatics. Medical men have in fact served the Society with a zeal out of proportion to their numerical strength. At the present time the number of medical fellows does not greatly exceed the number of peers of the realm on the Society's roll, but, in our own generation, Sir Shirley Murphy, Sir Arthur Newsholme, Dr. Reginald Dudfield, Dr. T. H. C. Stevenson, Prof. Major Greenwood, and Sir William Hamer have been very active members; the three survivors, Newsholme, Hamer, and Greenwood, are members of the council now in office. In earlier times the Society owed much to the labours of four medical men, each of whom became president. William Farr was president in 1871, William Augustus Guy in 1873, T. Graham Balfour in 1888, and Frederic J. Mouat in 1890. Of course, as a statistician, the name of Farr stands first—indeed, we need not restrict our list to medical presidents if we wish to put the name of Farr at its head—but in the grateful memory of the Society the name of William Augustus Guy (1810–85) has precedence of any other, lay or medical. Guy was an enthusiastic statistician, his first contribution to the *Journal*, "On the Value of the Numerical Method as applied to Science, but especially to Physiology and Medicine," appeared in the second volume, his last in the forty-fifth volume; he was hon. secretary from 1843 to 1868, and at his death bequeathed a large sum of money to the Society. In his honour, the medals presented by the Society to eminent statisticians are called Guy medals and bear excellent portraits of the Society's distinguished fellow and benefactor.

With the increasing emphasis put upon the preventive aspects of medical science—not to speak of an increasing resort to quantitative methods in the evaluation of clinical data—the importance to our profession of the science for which the Royal Statistical Society stands becomes greater. We hope that in the second century of the Society's existence the proportion of its medical fellows will increase and that their enthusiasm may match that of Farr and Guy.

MALARIA IN THE ARMY IN INDIA

THE introduction of a new method of treatment for any disease is an event; malaria is of such importance among human ills that the finding of a drug to supersede quinine would be little less than a revolution. Isolated therapeutic trials may or may not hold when tested out in the light of a wider experience; the public health commissioner with the Government of India has had to ask himself exactly how much the Army in India has profited from recent developments in malaria therapeutics. His answer is contained in the second volume of a report recently noticed in this column.[1] It would be too much to expect that malaria had surrendered pride of place as the chief scourge of the Army in India. It still accounts for 14·5 per cent. of admissions to hospital for all forms of injury and disease, and during 1932 totalled some 4634 cases; this does not include out-patient attendances, nor does it give any idea of the loss of general efficiency caused by malaria. But of a steady improvement during the last few years there can be no doubt, for the rates per 1000 sick with malaria have fallen from 291 in 1928 to 91 in 1932; and that in spite of the fact that climatic conditions in 1932 were favourable for an outbreak and that anti-malaria measures had been curtailed on grounds of economy. Presumably, then, some new factor has been introduced which has influenced the situation. Partly by a process of exclusion, partly from accumulating clinical evidence, the conviction is growing that a more extensive and intelligent use of Plasmoquine is mainly responsible for the good record of 1932. That this year, like its three antecedent years, was liable to a high malaria incidence, is made likely by the number of sufferers among the Indian troops—a proportion considerably in excess of former years—who were not treated with plasmoquine, and who do not contract malaria in cantonments but in their native villages. Although the amount allotted to sanitary and engineering field works was only 10*d*. per head of the [illegible] (as compared with £1 15*s*. 4*d*. for similar measures in the Panama zone), yet there has been a steady improvement in the quality of the anti-malaria measures, owing to the influence of Lieut.-Colonel J. A. Sinton, V.C., who directs the malaria survey of India. Anti-malaria officers who have been through the course at the experimental station at Karnal are filled with an enthusiasm which rises superior to the many practical difficulties with which they are faced.

On the prophylactic value of quinine the consensus of Army opinion is favourable on the whole, mainly because it diminishes the symptoms and reduces the liability to pernicious attacks of subtertian fever. The prophylactic value of plasmoquine was tried out on a large scale in Burma between September, 1931, and February, 1932. Well over 5000 officers and men took part in this experiment. The dose given was 0·02 g., above which toxic effects are occasionally observed, and it is probable that 0·03 g., in combination with quinine or atebrin, would be more effective. It is clear however that the smaller dose has a definitely delaying action without interfering in any way with the subject's physical activities and general well-being. On the whole the results of the Burma experiment were good, plasmoquine undoubtedly materially reducing the relapse rate. It was generally given in combination with quinine; atebrin was introduced too late in the season for any conclusions to be reached about its comparative value.

[1] THE LANCET, March 17th, p. 581.

LANARKSHIRE MILK EXPERIMENT CONFIRMED

It will be remembered that during a period of four months in 1930 an investigation on an unprecedented scale was carried out in Lanarkshire to determine the effect of adding extra milk to the diet of school-children. Grade A tuberculin-tested milk was supplied raw to 5000 children of 5 to 12 years of age, while another 5000 children received the same milk after it had been submitted to low-temperature pasteurisation. Ten thousand children served as controls. At the beginning and end of the investigation the children were measured to the nearest eighth of an inch in height and to the nearest ounce in weight. The results, which were recorded[1] by Leighton and McKinlay, showed that the addition of milk to the diet led to an increase in the rate of growth as reflected both by height and weight, and that in so far as the conditions of the investigation permitted there was no apparent difference in their effect on growth between raw and pasteurised milk. This second conclusion was challenged by Bartlett, and by Fisher and Bartlett, who, on analysing the figures in a different way, satisfied themselves that the growth-response of children on raw was greater than that of children on pasteurised milk. The whole plan of the investigation was criticised[2] by "Student" on the grounds that raw and pasteurised milk were never given in the same schools; that the initial heights and weights of the children in the control series were greater than those of the children who were given milk; and that since the children were weighed in their clothes, and since the first weighing was in February and the second in June, there may have been a differential shedding of clothes by the more prosperous control and the less prosperous milk-fed children. "Student" suggested that in a new investigation on the comparative value of raw and pasteurised milk probably more information at much less cost would be obtained by working with identical twins.

Though this principle was not strictly applicable to the Lanarkshire experiment, it occurred to Prof. Karl Pearson that a great deal of information might be obtained if the children in each class—controls, raw milk feeders, pasteurised milk feeders—having approximately the same height and weight could be compared. This suggestion was followed up, and Miss Ethel M. Elderton, D.Sc., working in Prof. Pearson's laboratory, has recently recorded[3] the results of such an analysis. The original cards were obtained and sorted for each sex into the year of birth. Selection was then made of a child from the control series who was of the same initial height, the same weight within 8 oz., and the same age within a month, as one who had been given milk. The following comparisons were then made: controls with raw milk feeders; controls with pasteurised milk feeders; and raw with pasteurised milk feeders. By this method only the average children could be compared; the shortest and tallest, and the lightest and heaviest had to be excluded. It was found (1) that those who have extra milk generally gain in height over those who do not, and that the older girls gain more than the younger when pasteurised milk is taken, but that otherwise younger and older gain equally in height by having extra milk; (2) that those who have extra milk generally gain in weight over those who do not; that girls gain more than boys, and the older girls than the younger; and that this difference associated with age is greater when raw than when pasteurised milk is taken; (3) that there is no evidence that raw milk has an advantage over pasteurised or pasteurised over raw in increasing growth when the two are directly compared on this selected material; and that the question of the value of pasteurisation turns practically on the elimination of possible sources of disease, or on determining whether cases of certain diseases are less frequent when pasteurised rather than when raw milk is taken.

These conclusions are largely in agreement with those originally drawn by Leighton and McKinlay, and lend no support to the view that low-temperature pasteurisation produces a significant change in the composition and food value of milk.

LABORATORY DIAGNOSIS OF CHOLECYSTITIS

Two recent papers show how much can be done to clear up the diagnosis of acute and chronic cholecystitis respectively by laboratory tests. In the first,[1] Dr. Nils Liedberg, of Lund, Sweden, gives an account of 145 clinically certain cases of cholecystitis the majority of which had been followed systematically with sedimentation tests. His material also includes 31 cases of uncomplicated gall-stones, the diagnosis of which was in every case verified by operation and the microscopic examination of the gall-bladder. He found that during the first 24 hours of an acute cholecystitis there is, as a rule, no increased rate of sedimentation of the erythrocytes. During the second day 90 per cent. of the cases show an increased rate, the average one-hour rate being 29 mm. During the third, fourth, and fifth days this rate rises continuously, the average for these three days being 48, 57, and 61 mm. respectively. The sedimentation-rate appears to behave as if it were quite independent of any jaundice that may be present. In the majority of cases of uncomplicated gall-stones the sedimentation-rate is normal; in the rare cases in which it is increased the departure from normal is only slight. Dr. Liedberg concludes that the sedimentation test is, perhaps, better than any other in reflecting the pathological changes; it may throw light on the clinical progress of acute cholecystitis, provided it is carried out systematically. In chronic cholecystitis Dr. Etienne Chabrol and Dr. André Busson[2] have found the quantitative analysis of biliary pigments in the blood useful in diagnosis and as a guide to treatment. They publish a table which includes 45 patients who had been kept under observation for several weeks after a bout of pain without showing the least tinge of jaundice of the conjunctiva. Nevertheless, according to this table, 39 of these patients had a degree of bilirubinæmia well above the 2·0 mg. limit. These authors regard the normal limits of bilirubin in the blood-serum as 0·8–1·6 mg. per 100 c.cm. of serum, although it might be imprudent to diagnose hypercholæmia for any reading below 2·0 mg. The amount of cholesterin in the blood is less significant. After an examination of more than 200 patients, the authors found that the concentration of cholesterin in the blood-serum exceeded 180 mg. per 100 c.cm. only in every fourth case. They regard hypercholesterinæmia more as a sign of atheroma or chronic nephritis than of biliary lithiasis.

SYDNEY HOWARD VINES

THE number of medical men must be large who owe their first serious grounding in botany to Prof. Vines, the emeritus professor of botany at Oxford, who died on Wednesday, April 4th, at the ripe age of 84. His first Alma Mater was Cambridge, where, as a scholar and later a Fellow of Christ's College, he was associated from 1875 for the next 13 years with the remarkable group of men who were at that period making history in the science school. Although never becoming a qualified medical man, Vines began his career as a medical student, and was three years in the medical school of Guy's Hospital before gaining a scholarship which took him to Cambridge. There he did not continue his medical studies, but decided to specialise in botany. With that object he proceeded to work at Wurzburg under Prof. Sachs, whose text-book on botany he translated. He was then appointed university reader in the subject, while Charles Babington, "Beetles" Babington the great field-naturalist, still held the chair of botany. Vines expounded in his college and university lectures a new school of thought in regard to botany, developed on the association of the science with the manifold progress then being made in physiology and physiological anatomy. In 1886 these lectures were published and shortly afterwards the Students Text-book of Botany appeared, and immediately won for its author his prominent and popular place as a teacher. Vines was elected professor of botany at Oxford in 1888, and under him the department grew rapidly in size and importance, and when he retired from the chair in 1919 his honorary degrees, a distinguished series of them, reflected justly the wide esteem in which he was held by the educational world. The lives of Babington and Vines cover over a century of British botany, for Babington also lived till he was well over 80 years of age.

TONSILLECTOMY AND THE SCHICK REACTION

DESPITE the accumulation of material no final opinion can yet be formed about the correlation of tonsillectomy with diphtheria immunity. Contradictory results have been presented by reliable workers, some finding that children whose tonsils have been removed tend to be Schick-negative while others have noted no significant difference between children with and without tonsils. In seeking to analyse this discrepancy later observers have been careful to indicate the social conditions of the children they have examined. Schick and Topper worked in New York City and made their observations in children of a poor social grade; they found what they considered a significantly higher Schick-negative rate among tonsillectomised than among non-tonsillectomised children. Doull and Herman investigated medical students at Johns Hopkins University; Wheeler and his colleagues, ordinary school-children in Baltimore; Shaw, school-children in Chicago; and Burton and Balmain, school-children at Ilford; and none of these found a significant difference in the Schick-negative rate in the two groups of children. Dudley, in a careful study made at the Greenwich Hospital School, is indeed the only other investigator who brings support to Schick and Topper's original contention, but as Dudley has abundantly shown, the Greenwich school was something of an epidemiological museum so far as diphtheria was concerned. Certainly deductions from observations made there under the old régime must be generalised with caution. In the inquiry reported on p. 790 Dr. Buice's material consisted of children from a rural area in America and he again finds with the majority that tonsillectomy and Schick-immunity are not correlated. If positive deductions must be made, it is probably easier to make them from the study of rural populations, where the uncertain effects of waves of epidemic infection can be eliminated. At the same time it does not appear impossible that children belonging to heavily infected groups may as a result of tonsillectomy allow an entry of diphtheria bacilli and a latent immunisation effect as shown by the Schick test. It is at any rate noteworthy that both Schick and Topper's and Dudley's observations were made among children who must be looked upon as belonging to a heavily infected herd.

THE STUDY OF INEBRIETY

ON Tuesday Sir Humphry Rolleston, as president of the Society for the Study and Cure of Inebriety whose jubilee arrives this year, deeply interested his audience with the history of the society and of its founder, Norman Kerr. Kerr, who was born exactly one hundred years ago, started as a journalist and then entered Glasgow University where a society existed, supported by the students and their teachers alike, for the promotion of total abstinence. Kerr graduated as a doctor in 1861, and lived a life for the next ten or twelve years which familiarised him in a practical manner with the tragic concomitants and sequences of drunkenness. He was resident surgeon at a Lock hospital, he was medical officer to a line of steamers plying between Scotland and America—his experiences in Glasgow thus being reinforced by what he saw on the other side of the Atlantic—and he became surgeon-superintendent of the Glasgow Emigration Department of the Board of Trade. Then he came to London, and for the next quarter of a century conducted a large general practice in the neighbourhood of Regent's Park where his work as a parish medical officer brought him into close association with the life of slumdom, and where, going from door to door, he saw evidence of the evils to combat which he was resolving to devote his life. In association with the Church of England Temperance Society he assisted in the activities that led to the passage of the Habitual Drunkards Act, and after the passage of this Act he became honorary secretary to the Homes for Inebriates Association. This association founded the Dalrymple Home at Rickmansworth, and a large section of the work carried on here has been closely analysed in the *British Journal of Inebriety* by Dr. F. S. D. Hogg, for many years the licensee. In 1884 the Society for the Study and Cure of Inebriety came into being, and its activities under such fine presidents as Wynn Westcott, Mary Scharlieb, Claye Shaw, Alfred Pearce Gould, not to mention those who are still with us, have been steadily progressive. The society during its fifty years of endeavour has considered every aspect of the use of alcohol as an individual and a social disease, and many of the contributions to its journal will be remembered by our readers as having led often to discussion. The society has supplied evidence through which both the medical profession and the public at large can follow the reasoning, when the principle is maintained that drunkenness is not an excuse for crime, or when debate centres round the question whether alcoholism is itself a crime, irrespective of the criminal or anti-social behaviour to which its abuse conduces. Again where legal issues are raised in deciding whether, intention being the element of an offence, the delinquent had been mentally capable of forming an intention at all, the medical evidence may be both critical and difficult to follow. The activities of the Society for the Study and Cure of Inebriety are directed to the elucidation of these and allied difficult problems, and it can look back, at its jubilee, upon a valuable record.

Sir Humphry's address was delivered at the rooms of the Medical Society of London, and was preceded by a luncheon at the Langham Hotel.

UNIVERSITIES YEAR BOOK

THE Year Book of the Universities of the Empire for 1934[1] differs but little from its predecessors, and this is well for the time and thought that have been put into its production since the first issue in 1914 have resulted in a volume which could hardly be bettered for accuracy and ease of reference. The best evidence of its appreciation is the increasing care and promptitude, noted by the editor, with which the returns are made by the registrars or other officials of the institutions included in the book. Practically the only change is in the order of the overseas universities which have been altered to conform with the arrangement of the home universities. Additional information has increased the volume by about 30 pages but without increase in bulk. In the name of medical faculties we offer thanks to the Bureau and to Sir Frank Heath in particular.

RESEARCH IN MENTAL DISORDERS

FOR many years past the annual report of the Board of Control has been issued in two parts, the second of which is occupied with a record of the scientific research work done during the year in the institutions visited by the commissioners. Last year 51 of the 99 county and borough mental hospitals sent in reports, and we took occasion[2] to summarise the attempts being made to solve the problem of dysentery and typhoid in mental institutions. In the aggregate this work must account for a very large outlay in time, thought, and money, and it is of the first importance that research should be directed into profitable channels. More recently we indicated in a leading article[3] some of the basic difficulties in the way of eliciting the causes of mental illnesses from clinical data. The Medical Research Council has had an investigation committee dealing with mental disorders, but a reference to the successive annual reports of the Council shows clearly enough that the mental side of medicine has not had a very large share of the Council's attention. This is not to overlook that the expenses of important researches at the Cardiff City Mental Hospital have been defrayed by grants and that assistance has been given for work at the Maudsley Hospital and for an important inquiry into the ætiology of mental deficiency at Colchester. There will therefore be cause for rejoicing that the mental disorders committee of the Council has been reconstituted to include representatives not only of psychiatry, medical psychology, and the study of mental deficiency, but also of neurology, physiology, biochemistry, pathology, and genetics. The appointment of the new committee has been made by the Council in consultation with the Board of Control to assist them in the promotion of research. The chairman of the reconstituted committee will be Prof. E. D. Adrian, M.D., F.R.S., a member of the Council, and the following will also serve: Sir Hubert Bond, a senior commissioner of the Board of Control; Dr. Bernard Hart, University College Hospital, London; Prof. D. K. Henderson, M.D., Royal Edinburgh Hospital for Mental and Nervous Disorders; Dr. T. A. Ross, Cassel Hospital, Penshurst; Dr. E. O. Lewis, a commissioner of the Board of Control; Dr. C. P. Symonds, Guy's Hospital; Mr. J. H. Quastel, D.Sc., Cardiff City Mental Hospital; Dr. J. G. Greenfield, National Hospital for Nervous Diseases; Dr. F. L. Golla, Maudsley Hospital; and Dr. L. S. Penrose, Royal Eastern Counties Institution, Colchester. Sir David Munro, of the Council's staff, will act as secretary.

PROLONGED ARTIFICIAL RESPIRATION

ON another page Dr. Tookey Kerridge describes how a patient with respiratory paralysis attributed to progressive muscular atrophy has been kept alive by artificial respiration for over two years. The story is instructive in the first place because it shows a gradual replacement of manual methods by mechanical substitutes which have proved at least as effective. Secondly, it emphasises the necessity for such mechanical help, since not even the extraordinary devotion of this patient's friends and attendants could have kept him alive without it. And thirdly, we are left with an account of a simple and convenient machine—somewhat resembling Rudolf Eisenmenger's "biomotor"[1]—which ought to find many applications in practice. Nowadays, attempts to pump and suck air directly into and out of the lungs have been abandoned, and mechanical methods of artificial respiration follow Schafer's manual method in exerting and relaxing pressure on the abdomen and lower ribs. Schafer's method, contrary to general belief, is effective chiefly through compression of the abdomen, not the ribs; it makes use of the piston action of the diaphragm to empty and fill the lungs. In his "rocking method," F. C. Eve applies the same principle: he puts his patient on a trestle or stretcher which is seesawed about its mid-point, and the weight of the abdominal viscera raises and lowers the diaphragm and so aerates the alveoli.[2] Eve's apparatus is very simple, can readily be improvised, and appears to have no theoretical drawback except the possibility that stomach contents will be regurgitated and inhaled by the patient. The "rocking" principle can be applied, moreover, to the revival of new-born infants with asphyxia, and N. C. Forsyth[3] has found this effective and convenient. Other things being equal however (which they seldom are), the best means of applying artificial respiration for asphyxia neonatorum,[4] and, indeed most other conditions, is provided by the Drinker-Shaw respirator. This large metal suit, in which the patient's body is exposed to alternating pressures, has often been described in our columns from the time when Prof. Drinker demonstrated it at the London School of Hygiene and contributed to THE LANCET an account of it with illustrations.[5] It remains to be stated, however, that the apparatus he left behind was bought by Messrs. Siebe Gorman and has been used, with some successes, at various hospitals in London and elsewhere, the expenses of its transfer being borne by the firm in question. It is surprising that until a week or two ago no institution in this country possessed a respirator of its own, and we have to congratulate the Hospital for Sick Children, Great Ormond-street, on having now obtained, through representatives of Imperial Chemical Industries, a new machine made by Messrs. Siebe Gorman and modified in accordance with the suggestions of Dr. F. J. Poynton. The fact that there are more than 20 such machines in New York City alone suggests that use will be found for the Great Ormond-street installation, and this will give those in charge of it an opportunity of studying the management of the patients, which is not in practice as simple as might be supposed. In poliomyelitis, in particular, respiratory paralysis does not always respond to artificial respiration in the way that is hoped, and the experience reported by N. L. Crone [6] of 24 cases treated at the Massachusetts General Hospital is not altogether encouraging.

THE PRESIDENCY OF THE ROYAL COLLEGE OF PHYSICIANS OF IRELAND

NOT for over 150 years has a President of the Royal College of Physicians of Ireland died while in office. The unexpected death, therefore, of Dr. F. C. Purser, a few weeks ago, gave rise to some conjecture as to the procedure that should be adopted by the College. It was commonly assumed that the vice-president would carry on the presidential duties until a new President would be elected, and that such election need not take place before next St. Luke's Day. A study of the legal position, however, showed that with the decease of the President the vice-president's powers disappear, since he only holds office during the pleasure of the President, and only acts as his deputy. The College found itself, therefore, upon Dr. Purser's decease, without any executive or titular head, and had to proceed forthwith to the election of a President. In the special circumstances it was found most convenient to invite a distinguished ex-President, Regius Professor T. G. Moorhead, who had completed his term of office last October, to resume the presidential duties. Accordingly, Dr. Moorhead has been elected President.

THE ROYAL MEDICAL BENEVOLENT FUND

THE annual general meeting of the R.M.B.F. was held on March 22nd in Chandos-street, Cavendish-square, the offices of the Medical Society of London, when satisfactory reports were placed before the audience by Mr. R. M. Handfield-Jones, the hon. secretary, and Dr. Lewis Glover, the hon. treasurer. It is satisfactory that the number of subscribers has been substantially increased; the total income during the year 1933 amounted to nearly £12,000, but unfortunately, however, the applications for help which had to be immediately met called for the expenditure of a little more than £12,000, the result in figures being a gap of £1435. This will have to be filled in the immediate future if the activities of the corporation are to proceed without reduction, and this we cannot contemplate as possible. Rather, urged by the increasing support of the Fund, which has taken place slowly during the past few years, we prefer to think that additional subscribers will be found among our readers and their clients. At the meeting some true incidents were narrated showing both the urgent need in which applicants to the Fund for help often are, and the painful circumstances which have led to their situations. Similar stories have often found their way into our columns, and we are certain have influenced those who read them to help the work of the Fund. They display the reasons for the Fund in the briefest and most striking manner. When we learn of the daughter of a medical man serving as a postman in a wild Scottish district, who does not apply for assistance until she is paralysed; and of another daughter of a medical man, a music teacher, whose plight when she asks for assistance is such that she has had to sell her violin to obtain food—when we hear such testimonies alike to the misery with which the Fund attempts to deal and to the courage of those whom it helps, we feel that the efforts of the promoters are indeed worth while.

At the conclusion of the meeting the honorary officers of the society, Sir Thomas Barlow as president, Dr. Glover as hon. treasurer, and Mr. Handfield-Jones as hon. secretary, were re-elected. Mr. E. C. Pennefather, the secretary, will receive contributions from a list of supporters which calls pathetically for expansion at 11, Chandos-street, Cavendish-square, London, W.1.

A DONATION of £15,000 from Mr. Robert McDougall and one of £5000 from the Halley Stewart Trust has ensured continuance of the experimental fields at the Rothamsted Agricultural Station. It is unthinkable that the remaining £8000 required should not be raised by May 12th in behalf of activities that may be described without exaggeration as having made scientific agriculture in this country.

OUR news columns contain the announcement that the Garton prize and gold medal for an essay on the biological effects and mode of action of radiations upon malignant and other cells has been conferred upon Dr. Hector Colwell, who has long been associated with such work at the Middlesex and King's College Hospitals. The prize is of the value of £500, and is awarded by the British Empire Cancer Campaign. A second award has been made to Dr. F. G. Spear, of the Strangeways Research Laboratory, Cambridge, and his collaborators.

FOURTH INTERNATIONAL CONGRESS OF RHEUMATISM. This congress has already been announced in our columns; it is to be held in Moscow from May 3rd to May 6th, and representatives from many European countries and from America will be present. The programme is as yet provisional, but on May 4th the subjects to be discussed, coming under the head of pathology, will be the general pathology and pathogenesis of rheumatic fever; the incidence of nutrition as a factor in treatment; and the clinical aspects of rheumatism in children. On May 5th the discussion will largely turn on the balneological treatment of rheumatic patients, when the mud *régime* in affections of the locomotive apparatus, and the indications for the use of sulphur saline waters and radio-active baths will be discussed. Further subjects announced for papers or debate are the use of spa methods outside the spa, and the results to be obtained from a combination of balneological and physio-therapeutic treatment. The representatives at the congress from Great Britain are Prof. A. P. Cawadias and Dr. Bernard Schlesinger, with Dr. W. S. C. Copeman as official representative of the Royal College of Physicians of London.

The Society for Cultural Relations has in hand arrangements for a group of doctors to visit Moscow on the occasion, and the details can be obtained at the office of the society, 1, Montague-street, London, W.1. Visitors can travel overland via Berlin and Warsaw or by boat to Leningrad. During the visit opportunities will be found for members of this group to visit medical and social institutions in which they are interested, and to meet Russian physicians engaged in similar work.

PROGNOSIS

A Series of Signed Articles contributed by invitation

II. PROGNOSIS OF DIABETES IN CHILDREN

MANY doctors still consider that the diagnosis of diabetes mellitus in childhood involves not only a serious but also a gloomy outlook for the child's future. Serious it certainly is, but no gloomy prognosis is justified in this insulin era. This optimistic view demands support, especially for those not fully familiar with what insulin therapy can do. Dr. Priscilla White has recently published a book on "Diabetes in Childhood" based on a study of the large number of children treated in Dr. E. P. Joslin's clinic in Boston. In her introductory sentence she says:

> "Before the discovery of insulin the mortality of diabetes in childhood was nearly 100 per cent., and to-day diabetes as a cause of death in the young has disappeared nearly to the vanishing point."

She supplies figures to show that early death can be replaced by continued health, and a similar experience is confirmed from all diabetic centres. Dr. White devotes a chapter to diabetic children surviving diabetes for ten or more years, of which she had 72 living in 1931. Of these 15 were in college, 26 were employed, and 4 were married. She points out that five years previously it was possible to find records of only 13 cases in the entire world who had diabetes in childhood and had survived ten years. The figures of my own cases (under 16) are worth recording as they show a difference between hospital patients and those under better social conditions.

	Numbers.	Deaths.	Per cent. living.
Hospital patients	59	6	90
"Private" patients	69	1	99

These figures have no statistical value since they do not take into account the survival time in each individual case. Some of these children have survived ten years, others have only been a year or so under treatment. I think, however, that they are of some value as an indication of the difference between private and hospital patients.

To ensure such good results continuous care and treatment are certainly necessary and in practically every case insulin injections. There is no question of invalidism or prolonged hospitalisation for these children, but a routine of controlled diet and insulin is essential and the prognosis depends almost entirely on its efficiency. Let us see what this involves.

At first, on diagnosis, most diabetic children are seriously ill and suffering from a heavy ketosis. Starvation will often precipitate coma and insulin is usually needed at once. The child should be placed on an adequate diet, liberal in carbohydrate and total calories and the correct amount of insulin carefully worked out to metabolise it. Two, very rarely three, injections a day are necessary. This initial treatment can, in my opinion, be carried out with full efficiency only in institutions where special facilities and experienced skill are available. Most practitioners rightly enough hesitate to undertake this part of the treatment.

It is essential also that careful arrangements be made for carrying on this treatment at home. The parents, or a special nurse or nannie, must be taught full details about dieting and how to suit the child's tastes by providing variety. Someone in the house must also be skilled in insulin injections and preferably also in watching progress by urine tests for sugar and perhaps acetone bodies. A daily routine is necessary which no practitioner can supervise in full and constant detail, but he should be familiar with the case and ready to advise when the routine is upset. Most children over 10, and some still younger, soon become capable of managing their diet and injections without any worry. Indeed I find that whatever strain may result seems to fall not on the affected child but on the anxious parents. The child's life and habits are practically normal and it soon accepts everything as normal routine. Clear instructions must also be given as to variations in treatment during illness and infections, when the failure to modify treatment may allow severe ketosis and even coma to develop in a few days.

When the above conditions are observed the *physical* outlook is entirely hopeful and normal. Certainly no one could pick out these diabetic from normal children in a bus, a school, or a hospital department. Growth and development proceed normally and average weight is maintained. Puberty ensues at the usual age, except in some cases treated on undernutrition diets with insufficient insulin. A few of these remain stunted in spite of a later change to a higher level of nutrition. The poorly treated may have several physical abnormalities. When the carbohydrate has been too low and the calories have been mainly provided by fat, continuous ketosis and a large fatty liver may be found. In still more uncontrolled cases with continuous hyperglycæmia, opacities may develop in the lens and operation for cataract may become necessary. Some workers declare that most of these children develop arteriosclerosis, minor but appreciable by refined methods of examination, but I have not noticed this in many cases. I believe all complications to be animadversions on the treatment employed and preventable with successful therapy. Many diabetic children have been kept in normal health with insulin for ten years and a few have already become parents.

The mental and social position and outlook of these children are surprisingly normal. Under 6 years they may be resentful and distressed by the injections for a few weeks, but rarely longer if properly handled. When diets large enough to satisfy hunger and to include variety are provided, as they should be, there is little difficulty with children breaking diets. As the diet provides ample supplies of fresh foods, vegetables, and vitamins, bowel function and dental development are usually above the average.

A *cure* of diabetes in children, or indeed at any age, is not within the present powers of medical science. Indeed practically all need insulin injections to ensure health and normal development. All oral substitutes for insulin are useless for children, although nothing is more desired by those interested in their welfare. The dose of insulin required varies from a few units to even a hundred in exceptionally severe cases. It is common to find small doses sufficient at the beginning of treatment and larger, even very large doses, necessary later, especially above 11 and 12 years of age. The years approaching puberty often seem to demand a greatly increased dosage, especially in girls. In all cases doses adequate to control the sugar ensure normal health, although the control of the diabetic condition may be more difficult in severe cases requiring large doses.

The outlook and prognosis therefore depend not on scientific therapeutic difficulties but on the practical subjected himself to severe and useless suffering; he asserted that the specialists had diagnosed his case wrongly, the operation had been unnecessary, and he was entitled to compensation of over £1000. The evidence showed that both professors had been treating the man free of charge, and that the patient's wife had made no attempt to obtain any information about her husband's condition before the operation. The defendants stated that they acted correctly and humanely in not disclosing to the patient that he was suffering from cancer, although the diagnosis was clear to them. It was only in the course of an exploratory operation that it was ascertained that the disease had gone too far to respond to operative treatment, and there was no other means of establishing the size of the growth. They had not communicated with the patient's wife, as she had never before asked for information, and they were not aware that the patient had a regular medical attendant. The plaintiff's legal adviser pointed out that the patient has a right to know what his condition is, and must give his consent to any major operation; but the defendants disagreed. Prof. Finsterer explained that as long as the public was convinced that cancer is incurable—though this is actually no longer true—he would never tell a patient flatly that he had cancer. Innumerable suicides would be the consequence of such a practice, and the shock of such a diagnosis has in several cases turned an operable patient into an inoperable mental wreck. Prof. Zweig also stated that under similar circumstances he would not tell a patient the truth bluntly. The opinion of medical experts was unanimously in favour of this attitude. The hearing was adjourned to obtain further evidence, but a discussion in medical circles showed that an overwhelming majority of medical men upheld the course taken by the two professors, though admitting that there are individual patients to whom the truth can safely be told.

NEW REGULATIONS CONCERNING NOTIFIABLE DISEASES

The Epidemics Act of 1913, which deals with the duties of the medical profession in cases of infectious diseases, has lately been brought up to date. There are two groups of notifiable diseases in Austria. The first group comprises scarlet fever, diphtheria, typhoid and paratyphoid fever, dysentery, cerebro-spinal fever, puerperal sepsis, typhus, small-pox, cholera, plague, recurrent fever, leprosy, trachoma, yellow fever, glanders, anthrax, rabies, chicken-pox, poliomyelitis, epidemic post-vaccinal and post-infectious encephalitis, and malaria. Every case or suspected case of these diseases, and every death due to them or suspected of being due to them, must be reported to the local health authorities. The only exception is puerperal sepsis; suspected cases of this disease need not be reported. The second group contains diseases which are to be notified only under certain conditions. They are measles, whooping-cough, and mumps in places such as spas, health resorts, and watering places, and in schools and institutions where there are children under 15 years; rubeola in such schools and institutions; influenza in Vienna; active tuberculosis of the lungs and larynx in hospitals or tenements, or where infection is likely; other forms of tuberculosis when the patients live in tenements where there are children under 12 years; and venereal diseases (gonorrhœa, ulcus molle, syphilis) if transmission is feared. Doctors are also bound to report venereal cases if the patients evade treatment, but the greatest care must be taken to ensure strict secrecy. In all cases of compulsory notification (Group I.) a final report must be sent to the same health authority when the infection is at an end; this is also required in cases of measles, rubeola, whooping-cough, and mumps, which have been notified. A medical man who fails to comply with these regulations is liable to a fine not exceeding 2000 Austrian shillings (£65) for the first group, 500 shillings for the second group, and 40 shillings for cases of tuberculosis. If a correct diagnosis cannot be arrived at without laboratory tests the physician may avail himself, free of charge, of the services of a laboratory attached to a municipal or local hospital. The new regulations also deal with the problem of infectious cases which are nursed at home.

THE DEVELOPMENT OF THE BRAIN

At a recent meeting of the Biological Society Prof. Versluys, the zoologist and biologist, read a paper on the volume and capacity of the brain. According to the researches of Dr. Dubois, the teaching of Darwin that the brain has enlarged in correspondence with increased demands upon it is erroneous. On the contrary research has shown that the volume of the brain has developed by leaps and bounds, and that this development is due to intrinsic factors whose ultimate cause is the reduplication of the nerve-cells. The increase in size produces an increase in efficiency and enables the individual to lead a more complicated life. But it is the increase in the size of the brain which comes first. In applying these principles to human development, Dubois draws the following conclusions. The brain of man in remote times was bigger than his needs demanded, and he only gradually learned to make proper use of its possible efficiency and qualities. The Neanderthal man had a brain equal in size and number of nerve-cells to the brain of a man of to-day. To-day any Negro child from Central Africa is able to carry out complicated studies at a university which his parents, endowed with the same brain, entirely ignored. Dubois considers that the explanation of how man has gained faculties and qualities which have no direct practical value in the struggle for life—for instance, higher mathematics or philosophy—is that he always had brain cells which were capable of such development. This theory raises the question whether modern man has not already attained the peak of efficiency which the size and volume of his brain make possible.

PAYING PATIENTS AT THE MIDDLESEX HOSPITAL

No one who contemplates the uninspired façade of the new Woolavington wing of the Middlesex Hospital could guess with what cunning its interior has been modernised. The conversion of a block which used to provide accommodation for nurses and residents to a wing for paying patients has been made possible by the generosity of Lord Woolavington, who provided the cost of a complete reconstruction, little more than the outer shell remaining. The approach is through the courtyard of the hospital (Fig. 1) or through a separate entrance in Cleveland-street, and since the wing remains an integral part of the hospital building the patient can be taken to any department for special investigation or treatment—for example, to be X rayed—without having to go out of doors. In the main, however, his needs are met within the wing. Two operating theatres and anæsthetic rooms are provided, and smooth working lifts and rubber-covered corridors minimise

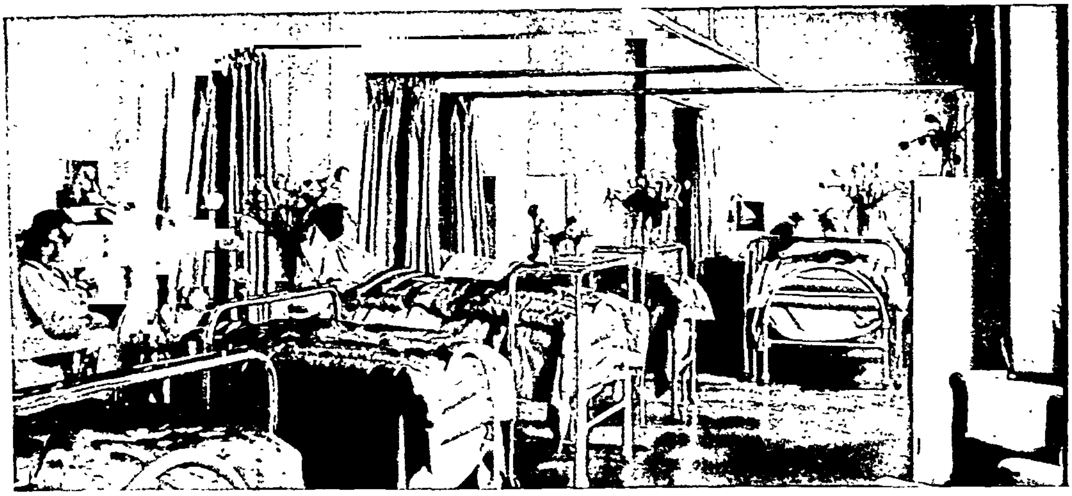

FIG. 2.—A ward with curtained cubicles.

the vibration and noise too often associated with movements of patients in hospitals. The rooms themselves, whether containing one bed or six, are furnished attractively with the comfort of a bedroom at home rather than the austerity of a hospital ward. Each bed has a silk eiderdown with curtains to match, and so arranged that the patient has some free space all round his bed and can see out of a window without being overlooked by his neighbours. He has also (Fig. 2) a really serviceable bedtable, with metal legs, and a black glazed top on which there is room for his own flowers and books as well as for a food tray, and a switchboard with plugs for bell, reading lamp, telephone, and wireless, as well as for any electrical apparatus which may be necessary for diagnosis or treatment. He is not worried by the sound of other people's bells, because no ring is audible; the bell actuates a red light outside the room which can only be extinguished by a switch at the patient's bedside. Radiators and electric heaters are provided, but each room has a grate for an open fire if this is preferred by the patient.

FIG. 1.—Garden front of the Woolavington wing.

The dietary is in charge of a trained food supervisor, and the patient has a choice of menus for each meal. Precautions are taken to ensure that meals are served hot, and that any special diets ordered are presented in varied and palatable forms. A sister-superintendent is in charge of the nursing services, and a high proportion of fully trained nurses is employed. Patients may be visited by their friends, subject to medical approval, on any day between 11 A.M. and 12 noon, and between 3 P.M. and 6 P.M.; a waiting room for guests is provided.

Altogether 64 beds are available in the wing, divided as follows: 12 beds in curtain cubicle wards at four guineas a week; 28 single rooms at seven guineas and 16 at twelve guineas; and 7 to 9 cots for children at charges ranging from four to ten guineas a week. Accommodation for mother or nurse can be provided where desired. Services charged as extras are special nursing and massage and electrical treatment. Only patients who are paying reduced fees to the physician or surgeon in charge are admitted to rooms at seven guineas a week or under, and the total professional fees paid by these patients will not exceed fifty guineas. Every patient admitted is under the care of a member of the honorary medical staff of the hospital, but practitioners are given every facility for visiting patients and may collaborate in their treatment by invitation. Altogether the arrangements here made for the convenience of paying patients seem to be in every way admirable.

THE HAMMERSMITH HOSPITAL.—In reply to inquiries we are happy to state that the plans of the new British Postgraduate Medical School, reproduced in our article last week, were drawn up in the architect's department of the London County Council. The architect to the L.C.C. is Mr. G. Topham Forrest, F.R.I.B.A.

GENERAL MEDICAL COUNCIL

ELECTION OF A DIRECT REPRESENTATIVE

NEXT Tuesday, April 17th, voting papers will be sent out for the election of a direct representative for England and Wales on the General Medical Council, to fill the place of Dr. Christine Murrell, who died before taking her seat. Two candidates have been nominated—viz., Dr. H. G. Dain and Dr. E. A. Gregg.

Direct representation of the registered medical practitioners in the United Kingdom dates from the Medical Act of 1886, which allotted three to England and Wales and one each to Scotland and Ireland. Sir Norman Walker has now represented the practitioners of Scotland since 1907 and Dr. Leonard Kidd the practitioners of Ireland since 1906. The number of direct representatives for England and Wales was increased to four and quite recently to five, the senior representative being Sir Henry Brackenbury who has held office since 1925. Dr. E. K. Le Fleming and Dr. J. W. Bone were first elected in 1928 and Mr. Bishop Harman in 1929. The term of office is five years, but a direct representative is capable of re-election. It is some time since there has been an election, for Dr. Bone and Dr. Le Fleming were re-elected last year without contest. The most recent contest was in November, 1929, when Dr. Arthur Haydon contested without success the re-election of Sir Henry Brackenbury and Mr. Bishop Harman. In the previous November Dr. Gordon Ward and Dr. Gregg contested the re-election of Dr. Le Fleming and Dr. Bone unsuccessfully at the end of their first period of office. It was remarkable that on this occasion more than half the possible voters took no part in the election, although Dr. Ward and Dr. Gregg asked for a mandate from the general body of practitioners to overhaul the existing constitution of the Council in the light of defects which they considered had emerged during its 70 years' existence.

We print below the election addresses of the two candidates for the medical suffrage. Dr. Dain, who is chairman of the Insurance Acts Committee, has not stood before. It may be recalled that he has already been selected by a plebiscite of B.M.A. members from a list which included the names of Lady Barrett, Mr. R. G. Hogarth, F.R.C.S., Dr. J. S. Manson, Dr. L. A. Parry, Dr. Ernest Ward, Dr. A. Clarke Begg, Dr. S. Morton Mackenzie, and Dr. H. Vicars. Dr. Gregg is the candidate of the Medical Practitioners' Union and, as noted, has already stood for representation.

Dr. Dain's Election Address

To registered medical practitioners in England and Wales

At the request of many of my friends I am offering myself as a candidate for election to the General Medical Council to fill the vacancy recently announced.

It is recognised on all sides that the directly elected representatives of the profession occupy a position of peculiar responsibility, since the General Medical Council is so largely made up of those appointed by the Royal Colleges, Universities, and other licensing bodies—that is, of those whose experience is in consultative work and in teaching and examining medical students. For this reason it is most important that the directly elected representatives, forming but a small proportion of the whole Council, should have first-hand knowledge of the medical problems which arise in general medical practice: in other words, that they should be able to represent the interests and the point of view of the great body of their fellow practitioners who, having been taught medicine, have never gone on to become teachers.

In seeking your support and vote in this election, I do so as one who is in active general practice, and has been for more than 36 years. The work of the practice includes all types of patients—private, national health insurance, and public medical service—and has made me familiar with the medical and economic problems commonly encountered by the family doctor.

During the last 20 years in a variety of medico-political work and offices I have had exceptional opportunities for meeting practitioners from many parts of the country and becoming acquainted with their views, and at the present time I can claim to be in very close touch with their outlook and experiences.

On the subject of medical education I hold the opinion that the curriculum with its necessary tests and qualifying examinations should always have in view the production of the well-educated general practitioner, and that detailed teaching in special subjects should be a matter for the post-graduate period. In the consideration of any future proposals to modify the existing scope of the curriculum I shall always have in mind the attainment of this object.

The educational, administrative, and legislative aspects of medical practice are to-day of such a character as to have heightened the importance and influence of the General Medical Council. It is therefore all the more desirable that the views of the private general practitioner should be amply represented and considered in the deliberations of that body.

Should you do me the honour to elect me it will become my privilege to assist in the work of the Council, to increase the efficiency, to maintain the dignity, and to improve the ethical standards of the profession to which we all belong.

Bournebrook House, Selly Oak, Birmingham.

Dr. Gregg's Election Address

General Medical Council Election

I have been asked by many of my professional colleagues to stand as a candidate in the forthcoming election to fill the vacancy on the General Medical Council, vice Dr. Christine Murrell, deceased.

I have decided to allow my name to go forward and solicit your support on the following grounds:—

(1) I have been engaged in general medical practice for almost 25 years, including panel practice since its introduction, and am intimately acquainted with the problems of those engaged in such practice.

(2) I have been associated with medical organisation during the whole of my professional life and have represented my colleagues for many years on the London Panel Committee, London Insurance Committee, Insurance Acts Committee and the London Public Medical Service. I have also been engaged in public work during most of this time. I have served as Councillor, Alderman and Mayor of the Metropolitan Borough of St. Pancras and have been chairman of almost every committee of the Council, including the public health committee, maternity and child welfare committee, etc. I have also been chairman of the St. Pancras Board of Guardians, prior to its being taken over by the London County Council, having, in the course of years, been chairman of the Hospitals Committee and other committees of that Board.

(3) I have always advocated increased direct representation of general practitioners on the General Medical Council and, if elected, I will take every opportunity to press this reform.

(4) I am satisfied that the present system of medical education requires considerable modification in order to enable medical practitioners now entering the profession to deal adequately with modern conditions of practice.

(5) I am also of opinion that some alterations are necessary in disciplinary procedure.

In connexion with any proposals for alteration in any of the above directions, I shall advocate that the view of the profession be taken.

I have had sufficiently long experience of service in a representative capacity to know that it is impossible to forecast in detail the line of action which circumstances may indicate should be taken. I can only assure those of my colleagues who do me the honour of recording their vote in my favour, that, as in the past, so in the future, my efforts will be directed in such ways as are most likely to be to their advantage as well as to that of the community in general.

Harrington-square, London, N.W.1.

PANEL AND CONTRACT PRACTICE

Temporary Residents

LAST year's panel conference referred the question of the treatment of temporary residents to the Insurance Acts Committee, which appointed a subcommittee to go into it. As a result Memo. M26 has been issued to panel committees in the hope of leading to some definite decision at the panel conference in the autumn. The matter is important financially to insurance practitioners, for while no one wishes that doctors who do attend insured persons when away from home should not be adequately paid, there are many instances on record of claims being made for treatment as a temporary resident when actually no treatment was given. The memorandum points out that the system of payment divides itself into two sections :—

(a) The crediting by the Minister on the advice of the Medical Distribution Committee of the practitioners' fund in each insurance area in proportion to the area's liability to be visited by temporary residents, and similarily debiting the fund of each area on account of the temporary residents leaving their home area.

(b) The method of payment for attendance upon temporary residents adopted locally.

Payment is made by the insurance committee from the local practitioners' fund of the area to which the temporary resident has come. This fund is determined each year after taking all relevant circumstances into consideration. The allocation to and the charges against it are based upon data, furnished by insurance committees, which show the number of medical cards accepted by practitioners as temporary residents and the number of attendances recorded on the medical records (continuation cards) returned to each committee. There are two categories of temporary resident : (1) the insured person who goes away to stay with friends or at an hotel, (2) the inmate of a convalescent home ; and the return gives the numbers in each category.

On these facts the distribution committee advises the Minister as to how much each local practitioners' fund shall be credited or debited. At the present time the value of an ordinary temporary resident is 8*s*., and that of a convalescent home temporary resident is 1*s*. When the amount of each local practitioners' fund has thus been determined centrally, its distribution amongst the local doctors is governed by the local distribution scheme for that area. These schemes vary in different localities. Three pay on an attendance basis; others pay in units, the unit being the amount received for an ordinary resident insured person each quarter (approximately 2*s*.). The number of units allowed for an ordinary temporary resident varies in different areas from ten to two, the average being five for England (10*s*.) and six for Wales (12*s*.); but since the local fund receives only 8*s*. for each ordinary temporary resident it follows that the loss from this fund by paying out (say) 10*s*. to the doctor attending a temporary resident case is borne by all the other doctors in that local area. Only 22 areas take care not to pay out more money for temporary residents than they receive from the central fund.

For convalescent home cases the local fund receives 1*s*. a case, and again taking the unit as equal to 2*s*. the number of units credited locally in respect of these patients, varying from 7 to ¼, gives a maximum payment of 14*s*. and a minimum of 6*d*., with an average of 4*s*. in England, 6*s*. in Wales, 4*s*. in Scotland. There is therefore an average local loss, borne by the practitioners of the area, of 3*s*. in England, 5*s*. in Wales, and 3*s*. in Scotland for every temporary resident of this class.

Such being the facts it may be asked why it is that local practitioners are willing to bear such losses. Possibly the explanation is that those areas in which convalescent homes abound receive so much more panel money per head than other areas without such homes that this loss has not been noticed. Some figures for the year 1933 will illustrate this point. They give the number of temporary residents (of both sorts) per 10,000 of the committee's panel, deducted or added, in various areas and the payment per capita on each doctor's list for this area:—

	Deduction.	Capitation fee.
London	52	8·2*s*.
Birmingham	32	8·5*s*.
Newcastle	29	8·6*s*.
Hull	18	8·3*s*.
Liverpool	19	8·5*s*.
East Ham	22	8·6*s*.
	Addition.	
Southport	237	8·4*s*.
Blackpool	498	9·2*s*.
Hastings	272	8·11*s*.
Cornwall	101	8·8*s*.
Isle of Wight	183	8·8*s*.

The normal capitation fee corresponding to these figures is 8·12*s*.

To take Blackpool as an example, as they receive payment for 498 temporary residents for every 10,000 insured persons on their list the doctors there receive 9·2*s*. for every person on their panel instead of 8·12*s*., the official rate (with 10 per cent. deduction). They do not complain about their local distribution scheme.

The convalescent home cases give rise to much dissatisfaction, for at present the 1*s*. per case is paid for all residents in convalescent homes whether they require treatment or not. The medical cards are collected from patients on arrival, signed by the medical officer, and forwarded to become credits to the local fund. Some homes have rules about routine examination upon arrival solely for the benefit of the home. If treatment and/or advice is not given on that occasion there would not appear to be any sound reason for payment to the doctor from health insurance funds. Medical officers are often in receipt of an honorarium for undertaking this work ; in such cases they are being paid twice for work (if any) done.

The Insurance Acts Committee suggests that panel committees should approach their insurance committees with a view to altering the local distribution scheme so as to provide that temporary resident credits will only be allowed in those cases in which a medical record (continuation card) is submitted containing evidence that medical treatment has been given. An examination of a routine nature for the purposes of the convalescent home or similar institution shall not count as treatment. With this the London panel committee has agreed.

Own Arrangements

When the National Health Insurance system was started it was thought—and quite rightly—that, as there would be many insured people attached to medical attendants unwilling to take service under the Act, some provision should be made for the continuance of such attendance. An "own arrangement" clause was therefore introduced under which insurance committees are empowered to allow insured persons to make their own arrangements for receiving medical attendance and treatment (including medicines and appliances), and, subject to regulations, to contribute towards the cost a total sum not larger than the committee would otherwise have expended in providing medical benefit for them. It should be noticed that discretion is given to insurance committees under this clause. In the early days of the national scheme doctors hostile to it advised all their patients who were entitled to medical benefit to apply for permission to make their own arrangements—with the result that insurance committees began to refuse, as many do now, even to consider such applications.

The figures for 1933 show that 50 insurance committees did not give any permission at all. On the other hand, Ipswich apparently gives permission at a higher rate than any other committee in England—viz., 118 for each 10,000 insured persons on its list. Other rates are: York 109, Oxford 83, Croydon 78, Birmingham 17, London 7, the average rate for England being 9·8. Some applications carry their justification on their face, such as that of a homœopathic patient whose nearest insurance homœopathic doctor lives a long way off but whose own homœopathic doctor is quite close. Nurses and other hospital employees are often allowed to make own arrangement with some member of the staff of the hospital by individual application. It is thought that as the unreasoning hostility to the Act has almost gone more sympathetic consideration might now be given to applicants who have some real cause for wishing to have their old family attendant look after them. But there is another form of own arrangement which is giving rise to trouble and was the subject of debate both at the last panel conference and at a recent meeting of the London panel committee. This is a collective application by the insured members of the staff of a hospital, asylum, or other similar institution to be allowed to make their own arrangements on an undertaking, to be signed by the chairman or other officer of the governing body of the institution, to provide medical attendance and treatment for the insured members of the staff who make such application.

What may happen is that an insured member of the staff is obliged to attend the doctor appointed by the institution—although he is supposed to have free choice—the obligation being made a condition of employment. This may work satisfactorily when the insured person lives in the hospital, but when he lives outside and falls ill the institution doctor cannot attend him at home and he naturally does not want to pay the outside doctor who does attend him, for he is entitled as an insured person to free medical attendance from the institution doctor, whom he has had to choose as a condition of employment but whose services he cannot get because he is living outside. For this "inside only" attendance the institution receives the whole capitation fee. There is no further medical benefit available to pay an outside doctor either for temporary resident treatment or emergency. The patient would therefore have to pay privately, although of course the private account might be sent for payment to the institution which has received the whole capitation fee.

If such a collective own arranger moves away (other than temporarily) outside the area of the insurance committee which gave permission, then the arrangement lapses and he becomes an ordinary insured person. The panel committee for London agreed, after much discussion, with the view expressed by the Insurance Acts Committee, that it is most undesirable for non-resident members of the staff of an institution to be required to make their own arrangements with the institution; the ordinary medical benefit arrangements are better for them. In the London area there are only three institutions (all hospitals) where the whole staff make their own arrangement for the receipt of medical benefit (including drugs), but it is not thought that these hospitals put any pressure on employees living outside to come into the scheme. There have been no complaints in London on the subject, although nurses taken ill at home or away on holiday do have to pay privately for their attendance—if nurses ever pay doctors at all—and get the money back from the hospital later if they can.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Comdr. (retd.) R. F. Quinton to be Surg. Capt. (retd.).

W. B. Taylor to be Surg. Lt.

Actg. Surg. Lts. (D) to be Surg. Lts. (D): D. D. Craig, W. L. Mountain, and S. R. Wallis.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Comdr. G. H. S. Milln is placed on the retd. list with the rank of Surg. Capt.

ROYAL ARMY MEDICAL CORPS

Lt. I. H. C. Morton to be Capt.

ARMY RESERVE OF OFFICERS

Lt.-Col. T. H. Gibbon, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

MILITIA

Maj. W. M. Biden retires on attaining the age limit and retains the rank of Maj.

TERRITORIAL ARMY

Maj. R. I. Dacre to be Lt.-Col.

Lt. C. N. Suter to be Capt.

Capt. H. V. Forster, having attained the age limit, retires and retains his rank, with permission to wear the prescribed uniform.

INDIAN MEDICAL SERVICE

Majs. N. D. Puri and J. B. Vaidya to be Lt.-Cols.

Lt. R. J. Jarvie to be Capt. (provl.).

Lt.-Col. C. R. O'Brien retires.

ROYAL AIR FORCE

Flight Lt. H. R. Clein is transferred to the Reserve, Class D (ii).

HONORARY PHYSICIAN TO THE KING

The King has approved the appointment of Bt. Col. J. W. L. Scott R.A.M.C., as K.H.P., in succession to Lt.-Gen. Sir Harold B. Fawcus (retd.).

LONDON OPHTHALMIC HOSPITALS.—At the annual meeting of the Royal London Ophthalmic Hospital, City-road (Moorfields Eye Hospital), it was stated that the very extensive scheme of reconstruction now in progress is estimated to cost £96,103. An anonymous donor has given £6000, and has offered a further £4500 provided that the new building can be opened free of cost, which involves the raising of a further £14,000 by the end of the year.—Thanks to legacies the Central London Ophthalmic Hospital closed last year with a surplus of £1463. The success of the new squint department has been so great that overcrowding has resulted, and it will be necessary to provide increased accommodation. Good use has been made of the Princess Marie Louise wing for private patients, and there has been an increase in the number of persons attending the ophthalmic clinics.

OBITUARY

STANLEY MELVILLE, M.D. Brux., M.R.C.P. Lond.

RADIOLOGIST TO ST. GEORGE'S HOSPITAL

WE much regret to learn the death on April 6th of Dr. Stanley Melville. He had not been in good health for some time and had suffered from anginous attacks, while injuries received and bravely endured in the course of his professional work had subjected him to much pain.

Stanley Melville, born in 1868, was a Liverpool man and was educated in his native city and at University College, London. He took the English double diploma in 1893, and returning to Liverpool held many appointments in connexion with the Royal Infirmary, being assistant in the ophthalmological and throat departments, house physician and resident medical officer in the lock wards. He held appointments also at the Liverpool Northern Hospital, and was for a time demonstrator of anatomy in University College, Liverpool. He came to London in the early 'nineties, took the M.D. Brux. degree, and practised in the neighbourhood of Earl's Court, while he also studied for the Bar and was admitted at Lincoln's Inn.

In 1898 he began to take a deep interest in the new science of radiology, and made such a good name for himself in the practice of his specialty that he was appointed radiologist in succession to the West London Hospital, to St. George's Hospital, and to the Brompton Hospital for Diseases of the Chest. He worked assiduously, with personal reason to know the risks incurred in those early days of radiological practice, for he incurred serious burns of the hands, while his writings on his subject, the result of personal knowledge, soon attracted attention. He was the author of the Diagnosis of Intrathoracic New Growths from the Radiological Standpoint, and contributed to this journal and other medical periodicals articles upon radiography, especially in relation to diseases of the chest. He now threw himself actively into the movement in this country for the better protection of X ray workers, and in 1921 became joint secretary of the British X Ray and Radium Protection Committee—the first of its kind in any country. In 1928 the British "recommendations on protection" were adopted internationally at the Second International Congress of Radiology at Stockholm, and Melville was appointed with Mr. G. W. C. Kaye, D.Sc., superintendent of the physics department of the National Physical Laboratory, joint secretary of the International Protection Committee.

DR. MELVILLE

[Photograph by Russell

Melville never spared himself in national and international movements for advancing radiological activities. He was, in his time, president of the Electrotherapeutics Section of the Royal Society of Medicine, president of the Radiological Section of the British Medical Association, secretary of the British Institute of Radiology, and secretary-general of the First International Congress of Radiology held in London in 1925. His was, indeed, the guiding hand for many years in the educational activities of the British Institute of Radiology, particularly in relation to the diploma in medical radiology and electrology of the University of Cambridge. He acted as examiner in radiology at both Cambridge and Liverpool Universities. He was one of the founders of the Society of Radiographers and its first president. A few days before his death he had accepted nomination as hon. medical editor of the *British Journal of Radiology* by the council of the institute. He was appointed chairman of the British delegation to the forthcoming Fourth International Congress of Radiology at Zurich next July, and had been singled out by the executive as the British authority to contribute to a discussion on the radiodiagnosis of pulmonary tuberculosis.

Calls upon Melville's services were numerous, for, in addition to his positions at St. George's and the Brompton Hospital, he was at different times consulting radiologist to the Midhurst Sanatorium, the Ventnor Hospital for Consumption, the Royal National Orthopædic Hospital, and the Grosvenor Hospital for Women, appointments from which he derived his extensive knowledge of the value of X rays in the diagnosis of lung diseases. This was the subject on which his final public address was made as president last year of the British Institute of Radiology, incorporated with the Röntgen Society. This address he concluded with the admission that he had at first regarded the X ray diagnosis of pulmonary disease with considerable doubt, but had grown with his experience to be thoroughly optimistic as to its future utility. He was also consulting expert to the Ministry of Health, in which capacity he rendered ungrudging assistance both to the central bureau and to local authorities.

Melville's great characteristic was service—service to his patients, his science, the State, and his friends. For all these he spent freely his powers, and was rewarded by the high regard of his fellow-men. He was a man of great personal charm, natural dignity, and unfailing courtesy. He held strong convictions and never hesitated to challenge a situation or policy which in his judgment was unsound or untenable, and would not serve the best interests of radiology. He maintained an enviable cheerfulness despite his damaged hands which frequently caused him much pain. His loss will be acutely felt by his many friends. The closing months of his life were clouded by the death of his wife, his beloved companion of many years. He died from heart trouble after a week's illness in a nursing-home in Wimpole-street, and deep sympathy will go out to his family now doubly bereaved.

Sir Humphry Rolleston, who in more than one direction of important work was Melville's colleague, writes: "British radiology has suffered a severe blow in the sudden death of Stanley Melville who, though long an ailing man, always presented a cheerful uncomplaining front to painful disabilities, evil strokes of fortune, and the prolonged illness of his charming wife, the companion of his advance from general practitioner in Nevern-square to the position he attained in the radiological world. Few of the pioneers of radiology in this country have done so much to secure its development on proper lines, to establish the status, provide adequate education, promote scientific work, and set up a qualification in the form of a diploma for radiologists. While doing much for skilled technical assistants or radiographers he was active in bringing about a satisfactory understanding of the relative provinces of medically qualified and of other radiological workers. The establishment of a diploma in medical radiology and electrology (D.M.R.E.) at Cambridge in 1919, and the necessary teaching and examinations, were his constant care. After the death in 1921 of his friend and colleague, Dr. W. Ironside Bruce, from aplastic anæmia, Melville's energy and whole-hearted devotion brought into being the X Ray and Radium Protection Committee, the first in the world, which though too late to save him from serious damage has been a service of incalculable value to present and future generations of radiologists. This alone marks him out as one who should not lightly be forgotten. Quietly and effectively he had long worked for the establishment of the British Institute of Radiology, incorporated with the Röntgen Society, and it is a satisfaction that he lived to be its president. Melville devoted the best energies of his life to promote the development of radiology without ever putting himself forward, hinting or asking for reward, but those who really knew the man recognise that the radiological world has lost a great soul."

CHARLES PORTER, M.D. R.U.I.

LATE MEDICAL OFFICER OF HEALTH FOR JOHANNESBURG

Dr. Charles Porter, who was for 23 years health officer for Johannesburg and had seen it develop from a mining camp to a university town of more than 200,000 inhabitants, died on March 7th at Muizenberg, Capetown, where he had gone on holiday. Born in Cork in 1864, he was educated there and later in Dublin, and at University College, London. In 1880 he won an entrance scholarship in the civil engineering school of the Queen's College, Cork, but soon transferred to the medical faculty with the intention of graduating for the Army or Indian Medical Service. In 1889 he graduated in medicine, with honours and exhibition, at the Royal University of Ireland. His eyesight proving a bar to military service he continued his studies, holding resident appointments at maternity and fever hospitals in Cork, and taking a certificate in mental diseases and the diploma in public health at Cambridge University. In 1890 he was appointed assistant medical officer of health for East Kent, and from 1893–98 he was M.O.H. for Stockport. The six annual reports issued to his council during that time are a record of his grasp of the social aspects of hygiene at a time when official public health was concerned rather with drains and nuisances. Under his stimulus the corporation of Stockport was one of the first, if not the first, to grapple practically with the question of maternal education. In 1900 Stockport teachers met the sanitary committee and agreed to arrange for the instruction of the elder schoolgirls in the feeding and management of infants, using as a guide the booklet drawn up by Dr. Porter and supplied by the sanitary committee. A health visitor was appointed to visit each school occasionally to supplement by demonstration and otherwise the instruction given by the regular teachers. This work was developed further by Dr. Porter's successor, Dr. Meredith Young, when he was transferred to Shropshire as its county medical officer. Called to the Bar at Gray's Inn in 1898, he was frequently employed as witness in local government and parliamentary inquiries relating to water-supply and sewerage purification schemes. In 1901 he became a vice-president of the Society of Medical Officers of Health, and in the following year he left for South Africa.

His earliest work of importance for Johannesburg was to draft a petition on behalf of the town council for the extension of the boundaries of the town, and he received special commendation for his execution of this task. The following year saw him advocating the establishment of a university in the town. For the rest he was fully occupied with the organisation of an efficient public health department in a rapidly growing community, the huge insanitary area of Burghersdorp providing a problem none too easy of solution. In turn he put through schemes for the purification of the city's water-supply, for disease prevention, child welfare, control of milk-supply, and disposal of refuse and sewage. He was consulting adviser to the Rand Water Board from its inception, a member of the Public Health Council of the Union, specialist adviser in military hygiene to the Union Defence Force, and a member of numerous Government Commissions relating to education, hospitals, mining regulations, prisons, and housing.

THE LATE MR. DAVID LEES

We have received further tributes to the strong character and wide knowledge of the late David Lees. Especially the work which he did in combating the effects of venereal disease have brought out testimonies to his energy and far-sightedness. At his funeral in Edinburgh a large attendance was representative of the medical profession and of the public movements in whose activities he had shared.

MR. LEES

[Photograph by Bacon

HERBERT ERNEST CUMMING, M.D., C.M. McGill, M.C.

We regret to record the death of Dr. H. E. Cumming, which occurred on March 17th at his house in Hereford. Born in 1888 at Ottawa, Cumming received his medical education at McGill University, where he graduated as M.D., C.M. in 1913. He was prominent in university circles, both as an able student and a fine athlete, and at the outbreak of war had just completed holding the house appointments at the Montreal General Hospital. For fine service in France during the war he received the M.C., and at the conclusion of hostilities came to London as house surgeon to St. Peter's Hospital for genito-urinary diseases. In 1919 he took the English double diploma and shortly afterwards went into general practice at Hereford, where his death will be much regretted.

ARCHIBALD BYRON MACALLUM, F.R.S.

EMERITUS PROFESSOR OF BIOCHEMISTRY, MCGILL UNIVERSITY

WE regret to learn the death on April 5th, in London, Ontario, of the distinguished physiologist Prof. Macallum.

Archibald Byron Macallum was born in 1858 in the Canadian city where he died. He was educated at Toronto University, had a successful career as a student, and was appointed immediately on graduation to the teaching staff. He was for three years lecturer on physiology in the medical school, and in 1891 became professor of physiology in the University. Seven years later he was appointed the first professor of biochemistry, a chair which he held till 1918, completing an association with the Toronto medical school which had lasted for nearly thirty years. In 1920 he was appointed professor of biochemistry in the University of McGill, a position which he held until 1929, being appointed emeritus professor on his retirement. During the interval between the two professorships, which occurred at the close of the war, he was active in the institution of the Canadian Industrial Research Council and became chairman of the organising body at Ottawa; his energy and resourcefulness made a success of the movement, and his retirement from that position was attributed to political reasons. He then transferred his services to the sister university in Montreal.

Prof. Macallum's literary activity was considerable, and he had much to write about that was founded upon his own personal researches. Such papers as those read before the Royal Society on the distribution of potassium in animal and vegetable cells, and on the nature of the silver reaction in animal and vegetable tissues, read before the Society in 1905, showed his extreme ability in conducting difficult and elaborate investigations as well as the power of stating conclusions clearly. He was elected F.R.S. in 1906, and from that time forward his contributions to British and Canadian and American scientific literature stamped him as a leading thinker and actor.

Macallum married Minnie Isabel, daughter of the late John Strachan Bruce, of Cornwall, Ontario, by whom he had three sons.

CORRESPONDENCE

DETERRENT MATERNITY FEES

To the Editor of THE LANCET

SIR,—At a time when maternal mortality is discussed so freely in both medical and lay papers, and when it is acknowledged that antenatal care and management is in great part the means for the prevention of this lamentable mortality, it seems strange to me that the Lindsey county council should pursue a course which has the effect of acting as a deterrent to patients and their doctors from applying for treatment.

A patient of mine, a primipara, in the ninth month of her pregnancy, was desperately ill with pyelitis. I applied to the county M.O.H. to have her removed to a hospital. She was taken there at once and treated most successfully and returned home in 18 days very pleased with herself and her baby. A few weeks afterwards she came to me in great distress with a bill she had received from the county council. The items on the bill were:

	£	*s.*	*d.*
Maintenance	8	13	8
Operation	3	3	0
Ambulance	3	6	0
	15	2	8

The husband is a wage-earner who receives £2 10*s.* per week, and they still owe for their furniture. He had filled in a form giving his means and liabilities, and received a request from the M.O.H. for the payment of the sum mentioned, being the cost to the council of his wife's treatment, by instalments if he preferred. It seems to me a case of giving with one hand and taking away with the other, and if poor patients know that bills of this size are to be sent to them it will be very difficult for doctors to persuade them to take advantage of the service provided by the county council.

If a woman has any symptoms of fever after a confinement she is cared for free of charge, and I am very strongly of the opinion that antenatal consultant and hospital treatment should also be free of charge.

I am, Sir, yours faithfully,

Scunthorpe, Lincs, April 4th. W. S. HALL.

MASTOPATHIA

To the Editor of THE LANCET

SIR,—In your leading article (p. 744) on Mastopathic and Chronic Mastitis occurs the following statement:—

> "Lenthal Cheatle and Cutler separate two distinct proliferative conditions, 'mazoplasia,' described as an exaggeration of physiological activity with epithelial desquamation, spontaneous disappearance at the menopause and no tendency to neoplasia. . . ."

Exactly what we say is that the only neoplasia we can definitely associate with the process is the formation of fibro-adenomata belonging to the type encountered at puberty and in the early years of life.

It is perfectly true to say that, during many years of examination conducted upon whole microscopical sections from normal and abnormal breasts, we have no morphological evidence whatever that the desquamative epithelial activity of mazoplasia changes into epithelial neoplasia. It is on this evidence that we do not consider the condition to be a precancerous one, nor one on which papillomata, nor any other kind of epithelial neoplasia, are superimposed.

I am, Sir, yours faithfully,

Harley-street, W., April 6th. G. LENTHAL CHEATLE.

To the Editor of THE LANCET

SIR,—May I call attention to words bearing on this subject in a book I published in 1911 entitled the "Disorders of Post-natal Growth and Development." Evidence was there given for the view that many chronic diseases which favour the declining periods of life bearing the termination "itis" and ranked as inflammation are in reality exaggerated forms of senile degeneration. The idea then so commonly held that degeneration is solely passive and atrophic is, of course, not in accordance with the facts, and if anyone is still of this opinion the histological studies of the tissues of aged dogs subsequently published by Goodpasture and Wislocki,[1] and by L. W. Smith,[2] and afterwards confirmed by an examination of the chief organs of 100 aged men and women by myself,[3] ought to convince them that senile degeneration is often expressed by a reversion to simplicity and proliferation.

[3] Tumors and Cancers, 1915, p. 259.

I therefore suggested the words "*presenile*," "senilate," "degenerative hyperplasia" as far more suitable for chronic fibrous or cellular or cystic enlargements of the breast (among other organs) than any of the words which imply inflammation. The excess of fibrous tissue, or of an embryonic type of cell, can hardly justify the use of the word inflammation in the absence of evidence of microbial invasion and of redness, heat, and discharge, three of its cardinal signs. On the other hand, the cells are of the low or debased type, such as might be expected to appear in an organ towards the end of its cycle of development while undergoing the dedifferentiation of degeneration. The evidence strongly favours the view that in the enlarged and cellular and cystic breast of the regressive phase of breast development we have not an inflammatory or constructive process but a degeneration—an amplified degeneration—in which under suitable stimulation or activation some of its cells might pass on into neoplasia and cancer.

I am, Sir, yours faithfully,

Reading, April 9th. HASTINGS GILFORD.

LYMPHADENOMA

To the Editor of THE LANCET

SIR,—On p. 736 of THE LANCET of April 7th, in a report of the recent discussion on lymphadenoma at the Royal Society of Medicine on March 27th, there is a misunderstanding that I should be much obliged if you would kindly give me the opportunity of correcting. I am there credited with saying that no evidence of specific allergy had been obtained, but that is, in fact, the very opposite to what I believe to be the case. In view of the absence of evidence as to the presence of larger micro-organisms, information was sought concerning allergy to a possible virus infection in lymphadenoma, and some cutaneous tests were carried out by Dr. James Maxwell with a boiled extract of dried lymphadenoma gland which Dr. Wilson Smith kindly prepared for us by the same procedure that he has already shown to be efficacious in detecting allergy to a known virus infection—namely, vaccinia. The results were described by Dr. Gow. Control cases and lymphadenoma patients in the acute stage of the disease were all negative, but in three instances of known lymphadenoma where the disease appeared to be in a resting stage positive cutaneous reactions were seen, and the largest one, reaching 3 cm. in diameter, was in a young woman back at work and in full vigour, who for the time being appeared to have completely recovered from the disease. Although we are still at an early stage, these cutaneous observations, coupled with the allergic reactions described by Dr. Gow with vaccines prepared from high dilutions of the patient's own gland suspensions are, I submit, definitely in favour of the view that a pathogenic agent of the virus class is operating in lymphadenoma.

I am, Sir, yours faithfully,

M. H. GORDON.

St. Bartholomew's Hospital, E.C., April 7th.

To the Editor of THE LANCET

SIR,—In the account of the discussion on lymphadenoma in your last issue (p. 737) I am reported as saying that the myeloses were malignant proliferation of the "leucopoietic system of the body." This should read "leucopoietic system of the bone-marrow"—or else "granulocytopoietic system of the body." Doubtless I was myself to blame for the mistake, but I should be glad to have it corrected.

I am, Sir, yours faithfully,

London, W., April 8th. F. PARKES WEBER.

MEDICINE AND THE RIGHT OF SANCTUARY

To the Editor of THE LANCET

SIR,—With reference to the correspondence on the evolution of professional secrecy in time of war, it is interesting to note that after the battle of Lützen a large number of soldiers were found to be wounded in the fingers. It was reported to Napoleon that these were voluntary (self) mutilations made to escape service. Napoleon ordered that two of those so wounded in each army corps should be shot. Larrey, the great military surgeon, resisted this edict. He constituted a medical jury which examined under his presidency 2632 wounded. He demonstrated that the wounds received in this way in all those examined by the jury indicated the bravery of those who had received them. Napoleon was at first greatly angered at the report, but after reflection he thanked Larrey and afterwards rewarded him handsomely. Larrey addressed a circular to the army surgeons: "You ought always," he wrote, "to heal and succour the guilty as well as the innocent, and you ought only to see the injured parts; the rest does not concern you." In 1871 in Paris "Versaillais" and "Communards" were admitted to the hospitals. The surgeons did their best for both factions: the rest did not concern them—it was not their affair.

I am, Sir, yours faithfully,

Gloucester-gate, N.W., April 8th. RUSSELL STEELE.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED MARCH 31ST, 1934

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 3 (last week 5); scarlet fever, 2812; diphtheria, 1091; enteric fever, 21; acute pneumonia (primary or influenzal), 1383; puerperal fever, 48; puerperal pyrexia, 121; cerebro-spinal fever, 31; acute poliomyelitis, 4; encephalitis lethargica, 6; relapsing fever, 1 (Hendon); dysentery, 12; ophthalmia neonatorum, 78. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on April 9th–10th was as follows: Small-pox, 11 under treatment, 1 under observation (*last week* 17 *and* 2 respectively); scarlet fever, 1663; diphtheria, 1777; enteric fever, 7; measles, 3670 (last week 35[illegible] 308; puerperal fever, 30 mothers (plus 1 [illegible] yelitis, 5; " [illegible] there were 20 babies (plus 12 mothers) [illegible] rum.

Deaths.—In 118 great towns, including London, there was no death from small-pox, 2 (0) from enteric fever, 153 (57) from measles, 14 (4) from scarlet fever, 51 (8) from whooping-cough, 47 (7) from diphtheria, 45 (19) from diarrhœa and enteritis under two years, and 94 (28) from influenza. The figures in parentheses are those for London itself.

The weekly total of fatal cases of influenza is again a little lower, the figures for the last few weeks (working backwards) being as follows: 94, 109, 115, 99, 96, 85. The fatal cases were widely distributed among 40 great towns, the highest number of deaths being reported from Birmingham 6, Stoke-on-Trent 4, Bradford, Liverpool, South Shields, Sunderland, Northampton, Walsall, each 3.

Measles also shows signs of abating, the figures for the last few weeks (working backwards) being 153, 187, 157, 141, 130, 119, 110, 78. There were 15 fatal cases each in West Ham and Liverpool, 9 in Middlesbrough, 5 in Leeds and Salford, 4 in Manchester. The deaths from measles during the first quarter of the year just past numbered 1315 compared with 411 during a similar period last year.

Whooping-cough caused 14 deaths in Liverpool, 6 in Birmingham, 3 in Oldham. Six deaths from diphtheria were reported from West Ham, 3 each from Hull and Leeds.

The number of stillbirths notified during the week was 238 (corresponding to a rate of 39 per 1000 total births), including 37 in London.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Reassembly after Easter

THE House of Commons reassembled on Monday, April 9th, after the Easter recess.

Housing and Slum Clearance

In the House of Commons on Monday, April 9th, on the motion to go into Committee of Supply on the Civil Estimates and Estimates for the Revenue Departments, 1934,

Mr. HICKS called attention to the administration of the Ministry of Health in relation to housing.

Sir HILTON YOUNG (Minister of Health) expressed the hope that the House, the local authorities responsible for housing, and public opinion as a whole would follow from month to month and year to year, during the five years' programme of the Government, the actual achievements of the housing authorities in order to make sure that the programmes were carried out in time to achieve what the Government believed to be capable of achievement within the five years. It should be realised that they were still in the period of acceleration, when the great new effort had not yet come to the peak of its achievement in regard to pulling down the slums and putting further houses in their place. They had, however, already achieved such an increase of speed in the work as to assure them that, if it was continued, they would achieve the programme in five years. In other words, they were going fast enough already to get the work done in five years. The actual acceleration of slum clearance was best shown by the figures of the resolutions declaring clearance areas. That was a critical point—the point when the slum was actually declared to be a slum, and its clearance and the provision of fresh housing accommodation were made inevitable and certain. In the first year of the dawn of the idea of a campaign on the slums, the year which began on Jan. 1st, 1933, 200 local authorities declared 894 fresh areas. In the three months from Jan. 1st of the year to the end of March, the number of fresh areas declared had been nearly 1000. Therefore in the last three months more areas had been declared than in the whole of the preceding year, and they had already multiplied the rate of progress in slum clearance by four in the carrying out of the programmes. The curve was going up, because some of the biggest figures they had ever had were those for last March, when 347 fresh areas were declared. That carried with it the promise of a future increase sufficient to enable them to work up to the peak to which they had to work to get the programme achieved in the five years. He hoped it would be possible to shorten the time which it took to get the schemes through, and with experience of the working of the Act he believed that the local authorities would be able so to organise their machinery as substantially to accelerate the progress of the work. The Ministry of Health would promote that in every way they could, and there would be no delay there. It was not possible to abolish the inquiries because if they did they would not be sure that they were doing the work that they thought they were doing, and they might also be doing very great injustice to owners of property.

With regard to the activity in small house building, in the six months to the end of last September between 55,000 and 60,000 small houses for the lower-paid wage earners were built by local authorities and private enterprise combined. That compared quite favourably with previous years, and it was encouraging to observe that that activity continued, according to the best available information, undiminished. The lesson experience taught was that an uncontrolled subsidy was useless to cure the housing difficulty. That was the whole basis of the Government's policy, and it was being developed stage by stage at present. The second foundation-stone of the Government's policy was that, by the programme now being carried out with the assistance of public funds, backed by the whole housing energy and public opinion of the country, the slums should be no more. When that organisation was completed and the attack launched on the slum evil, the Government could go on to deal with overcrowding. That was a matter which, when the time was ripe, as it would be before long, he would be able to develop to the House.

The motion to go into Committee was agreed to.

HOUSE OF COMMONS

MONDAY, APRIL 9TH

The Drought: Emergency Measures

Mr. ATTLEE asked the Prime Minister what was the present position with regard to water-supplies in the country and what measures were proposed to meet the conditions arising out of the drought.—Mr. MACDONALD replied: The reserves of many water undertakers have fallen to a low level for this time of the year. The Government have been carefully watching the situation and, because of the continued absence of abundant rains, are satisfied that emergency measures must be taken. Therefore, in view of the seriousness of the position, the Government propose to bring legislation before the House immediately. The Minister of Health will present a Bill to-morrow. The second reading will be taken on Thursday.

Cheaper Milk for School-children

Mr. HALL-CAINE asked the Parliamentary Secretary to the Board of Education whether he had yet received the proposals of the Milk Marketing Board with regard to the scheme for supplying cheaper milk to school-children.—Mr. HERWALD RAMSBOTHAM replied: The answer is in the negative.

TUESDAY, APRIL 10TH

Supply of Milk to Necessitous School-children

Mr. McENTEE asked the Parliamentary Secretary to the Board of Education if he would give a list of those local education authorities which were exercising their powers under Sections 82 to 84 of the Education Act, 1921, only to the extent of providing free milk for necessitous children.—Mr. HERWALD RAMSBOTHAM replied: The following is a list of local education authorities who, during the month of February, 1934 (the latest period for which returns are available), exercised their powers under Sections 82 to 84 of the Education Act, 1921, only to the extent of providing free milk for necessitous children.

GLASGOW POST-GRADUATE LECTURES.

WEDNESDAY, April 18th.—4.15 P.M. (at the Western Infirmary), Dr. John Gracie: Medical Cases.

Appointments

CUNNINGHAM, G. J., M.B. B.S. Lond., has been appointed Junior Assistant Pathologist to the Royal Sussex County Hospital, Brighton.

FINLAYSON, J. D., M.B., Ch.B. Glasg., Medical Officer of Health for Falkirk.

Certifying Surgeons under the Factory and Workshop Act: CHAPMAN, R. J., M.D., Ch.B. Edin. (Horsmonden, Kent); MOWLE, A. C., M.B. Camb. (Devizes); MURPHY, T. C., M.B. Ch.B., N.U.I. (Biddulph, Staffs); SOUTTER, J. S., M.B. B.S. Durh. (Hendon, Yorks); ZAIR, A. H., L.R.C.P. Lond., M.R.C.S. (Ludlow, Salop);

Vacancies

For further information refer to the advertisement columns

Albert Dock Hospital, Connaught-road, E.—Res. M.O. At rate of £110.

Altrincham Gener [illegible] H.S. At rate of £120.

Ashton-under-Lyn [illegible] Hon. Asst. Surg.

Assam Tea Estate [illegible]

Bermondsey Boro [illegible] £600.

Birmingham, Erd. [illegible] Asst. M.O. £650.

Bradford Royal [illegible] Surg., Res. Surg. O. £225. Also H.P. and two H.S.'s. Each at rate of £135.

Brighton Education Committee.—Asst. School M.O. and Asst. M.O.H. £500.

Bristol University.—Lecturer in Dental Mechanics.—£600–£700.

Burnley, Victoria Hospital.—H.P. At rate of £150.

Chester Royal Infirmary.—Hon. Asst. Radiologist.

Doncaster Royal Infirmary.—H.S. and Cas. H.S. Also H.S. to Ear, Nose, Throat and Eye Depts. All at £175.

Durham County Hospital.—H.S. £150.

Eastbourne, Princess Alice Memorial Hospital.—Two Hon. Anæsthetists. Also Res. H.S. £150.

East Ham Memorial Hospital, Shrewsbury-road, E.—Res. M.O. £200.

Hampstead General and N.W. London Hospital, Haverstock Hill N.W.—H.S. At rate of £100.

Harrogate Royal Bath Hospital.—Res. M.O. At rate of £156.

Hospital for Sick Children, Great Ormond-street, W.C.—Physician to Out-patients. Also Surgeon.

Huddersfield Royal Infirmary.—Jun. Cas. O. and Res. Anæsthetist. At rate of £150.

Ilford, King George Hospital.—H.S. At rate of £100.

Indian [illegible] Med. Officers.

Italian [illegible] *W.C.*—Hon. Asst. Phy.

Keighley [illegible] Asst. M.O.H. and Asst. School M.O. £500.

King's College Hospital, Denmark Hill, S.E.—Hon. Radiologist.

Lancaster Royal Infirmary.—Jun. H.S. At rate of £130.

Leamington Spa, Warneford General Hospital.—Res. Cas. H.S., &c. At rate of £150.

Liverpool, Broadgreen Sanatorium.—Asst. Res. M.O. £200.

Liverpool, David Lewis Northern Hospital.—H.P. At rate of £80.

London Homœopathic Hospital, Great Ormond-street, W.C.—Res. M.O. £100.

London Lock Hospital, 91, Dean-street, W.—Res. M.O. to Male Depts. At rate of £175.

Metropolitan Hospital, Kingsland-road, E.—Sen. and Jun. H.S.'s and Cas. O. All at rate of £100.

Middlesex Hospital, W.—Asst. Radiologist. £400.

Nottingham General Hospital.—H.P. At rate of £150.

Preston County Borough.—Asst. School M.O. £500.

Preston, County Mental Hospital, Whittingham.—Deputy Med. Supt. £750.

Queen Mary's Hospital for the East End, E.—Director of Pathology. £750.

Queen's Hospital for Children, Hackney-road, E.—Res. M.O. At rate of £200.

Reading, Royal Berkshire Hospital.—H.P., H.S., and Cas. O. Each at rate of £150.

Rochester, St. Bartholomew's Hospital.—H.P. At rate of £175.

Rotherham Hospital.—Cas. H.S. £150.

Royal College of Surgeons of England.—Examiner.

Royal Masonic Hospital, Ravenscourt-park, W.—Res. Surg. O. At rate of £250.

Royal Northern Hospital, Holloway, N.—Surg. Reg. Also Res. M.O.

St. Bride's, Pembrokeshire, Kensington Hospital.—Res. Med. O. £350.

St. Mary's Hospital for Women and Children, Plaistow, E.—Clin. Asst. to Gynæcological Dept.

Smethwick County Borough.—Sen. Asst. M.O.H. £750.

Southend Municipal Hospital.—Asst. M.O. £275.

Southend-on-Sea General Hospital.—Cas. O. At rate of £100.

South Shields, Ingham Infirmary.—Jun. H.S. £150.

Stoke-on-Trent, North Staffordshire Royal Infirmary.—Orthopædic H.S. £150.

West End Hospital for Nervous Diseases, Gloucester Gate, Regent's Park, N.W.—H.P. At rate of £150.

Western Ophthalmic Hospital, Marylebone-road, N.W.—Sen. and Jun. Res. H.S.'s. At rate of £150 and £100 respectively.

Wolverhampton and Midland Counties Eye Infirmary.—H.S. £150.

The Chief Inspector of Factories announces vacant appointments for Certifying Factory Surgeons at Kemnay, Aberdeen; and Kilbirnie, Ayrshire.

Births, Marriages, and Deaths

BIRTHS

ORCHARD.—On April 8th, at Kensington Court-place, the wife of Dr. Stuart Orchard, of a son.

RINK.—On April 3rd, at Welbeck-street, W., the wife of Dr. E. H. Rink, of a son.

SMALLSHAW.—On April 8th, at Sawley, Fir Tree-road, Epsom Downs, the wife of Dr. D. B. Smallshaw, of a son.

SPICER.—On April 2nd, at Welbeck-street, the wife of Captain W. R. C. Spicer, M.B., R.A.M.C., of a daughter.

MARRIAGES

MOWAT—GILCHRIST.—On April 3rd, at Overton Church, Lancaster, Allan Henry Mowat, F.R.C.S. Edin., to Edith Wilmet Swainson, youngest daughter of the late George Gilchrist, junior, Southport, and Mrs. Gilchrist, High House, Uley, Glos.

DEATHS

ANDERSON.—On April 7th, at Royal Masonic Hospital, W., Donald Drysdale Anderson, M.R.C.S., L.R.C.P., West African Medical Service, aged 37.

ANDERSON.—On April 6th, at a nursing home in Newcastle, James Anderson, M.D., aged 67 years.

DARKER.—On April 8th, suddenly, at Netherton Court, S.W., George FitzJames Darker, M.D., D.P.H., Barrister-at-Law, Middle Temple.

HARTT.—On April 1st, at Villa Montaigne, Lincombe Drive, Torquay, Dr. Charles H. Hartt, Colonel R.A.M.C., 2nd London Division (retd.), late of Greenwich, aged 87.

MACDONALD.—On April 7th, at Grasmere, Weymouth, P. W. MacDonald, M.D., J.P., formerly Medical Superintendent, Dorset Mental Hospital.

MELVILLE.—On April 6th, suddenly, Dr. Stanley Melville, Chandos-street, Cavendish-square, W.

PRICE.—On April 4th, at Addington-road, West Wickham, Kent, Dr. Ernest Henry Price, late of Cardiff and Brighton, aged 54.

SEPHTON.—On April 2nd, at the Manor House, Atherton, nr. Manchester, Robert Sephton, M.R.C.S., J.P., C.A., aged 90 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

ADDRESSES AND ORIGINAL ARTICLES

INDUSTRIALISED MAN AND HIS BACKGROUND *

By Leonard P. Lockhart, M.D. Camb.

MEDICAL OFFICER, MESSRS. BOOTS PURE DRUG CO., LTD., NOTTINGHAM; MEMBER INDUSTRIAL HEALTH RESEARCH BOARD

Not only in and around the main industrial centres but wherever economic life depends upon organised production and distribution there are certain aspects of industrial medicine which are also problems of general practice. With the possible exception of Greece in her prime medicine has rarely looked upon man's occupations with anything akin to approval. She has seen in them not so much a synthesis of mental, physical, and hygienic progress as a struggle carried on under conditions which did little to raise the level of the workers' lives. Ramazzini in the latter half of the seventeenth century noted occupational mutilations, poisonings, and ill-health, but we look in vain at contemporary social history for any constructive and preventive response to his disclosures. This apathetic attitude towards a great human problem was common to most social systems between the development of industrial technique and the coming of preventive medicine. To-day, however, occupational hazards are not merely recorded; they are studied and prevented in such a way that soon industrial disease ought to have been conquered.

Rationalisation of Industry

The solution of one problem is, however, but the beginning of another, which concerns not so much the prevention of occupational ill-health as the evolution of means whereby all work shall conduce towards a synthesis of mental, physical, and economic well-being in a social system where the rapid extension of applied science in daily life tends to falsify all predictions based on traditional data. We tend to regard this new order as beneficial or objectionable largely in terms of our personal reactions, but whether we manage to utilise it for man's progress or for his destruction depends entirely on the evolution and spread of ideas at present alien to the bulk of mankind.

Labour-saving machinery has increased, leading to the expansion of light industries and to the industrialisation of former handicrafts. There is a resulting tendency to employ less men and more women. Luxuries have gradually become popularised and standardised. An increasing proportion of employed persons are providing services as distinct from producing goods, while selling and distribution is almost an industry in itself. The power of the press, radio, and cinema in disseminating ideas or in manipulating mass emotions is enormous and the repercussions on employment and occupation incalculable. Clerical work is mechanised on almost an industrial basis and the potential output of each worker has been raised to the point at which increased non-working time, in the absence of vastly increased consumption both of services and goods, becomes almost inevitable either as unemployment or as increased leisure. The need for efficiency has called forth rationalisation with the unavoidable imposition of standardised methods of work, but the consequent reduction of individual scope has been somewhat offset by higher earning capacity and shorter hours. The larger organisations become the more must power be concentrated in fewer hands and rationalisation unwisely applied can almost sterilise an organisation of initiative and individuality. Rationalisation seems, however, to be a condition of survival in any highly technical society, and even medicine is not immune. We must, therefore, attempt some evaluation not only of its beneficial and pathological effects on health, but also of those attributes of it which we can utilise in the furtherance of preventive—or as Lord Horder puts it—constructive medicine.

BUT THE INDIVIDUAL WORKER HAS NOT CHANGED

A system which has evolved to the point of relieving man of much of his physical burden and of giving him a phenomenal power over the forces of nature has at the same time imposed a great and growing psychological burden. Looking at developing industrialism we might believe that man had taken certain tremendous strides and was capable of undertaking purely intellectual mental processes more or less divorced from emotional and instinctual traits. There is very little evidence to support this theory. Man may be more knowledgable, more richly endowed with technical skill, more capable of exercising power over the forces of nature, more adept at covering himself with a veneer of culture, but he is no more able to banish fear, jealousy, aggressiveness, or curiosity than were his nomadic forbears; nor does he appear to have grown markedly in wisdom. We have more complex means of expressing ourselves, more varied ways of masking our reactions and, moreover, we live in a world more pregnant with possibilities for touching up our emotional reactions—otherwise man is much the same. The conditions of the environment have, however, changed rapidly and changed fundamentally.

There are material advances such as better housing, clothing, transport, and food, but along with these there are factors which gravely disturb that sense of security and stability which is, in reasonable degree, so essential to physical and mental health and development. Rapid changes in means of production, in demand for particular goods, in organisation, and in ownership operating on an international scale hitherto unknown, have reduced work and employment for many to a precarious position. Uncertainty and a sense of insecurity may be inseparable from a phase of transition but they generate unhappiness and ill-health. Young men are having a very hard time to-day. Many jobs that formerly they could have done are now done by women with the aid of machines, while in the heavy industries, owing to immense world increases in production, employment is slack. It is no solution to replace women by men. Many of the jobs done to-day by women are not suitable for men. A man or boy is looking for a job for life on which to support a family. A girl wants a job until she marries, and quite apart from differences in pay is satisfied with a type of work that cannot possibly give satisfaction to a man. Other solutions than mere substitution must be found, but the fact that among general labourers one finds certificated officers of the Merchant Service shows how the channels for zeal and adventure are narrowed in our present state of economic transition. The disillusionments and harm done by short-term blind-alley occupations constitute another major problem, and militant political youth organisations abroad show how widespread is the need for outlets for male youth.

---

* Substance of an address delivered before the Bournemouth Medical Society, Feb. 14th, 1934.

Some Clinical Data

With these points in mind let us consider some clinical data. Every year about 50 per cent. of the insured population go sick for an average of very nearly four weeks each, resulting in the loss of over half a million years of working time. This excludes the first three days of absence and it takes no account of loss sustained by those who remain at work and yet are relatively unwell and below normal efficiency.

Unfortunately there is no large scale analysis of the certified diagnoses and we are therefore driven back, not to analyse official figures but rather to consider what we mean by the labels we attach to patients for certification purposes. My thesis is that since the law requires diagnoses limited to one or two words it gets what it demands, but that these stereotyped descriptions of highly complicated processes are with few exceptions valueless to the student of social problems. The certificates deal largely with symptoms or with symptom-complexes to which orthodox labels have been given. They do not necessarily convey the real and often complicated clinical picture. They are not notes for a medical registrar. They are merely evidence that a person is ill and is entitled to sick benefit. Let us regard them in that light and not try to deduce clinical information from what is in effect an order to pay out money.

In a large proportion of instances the certified disease is not a clinical entity but the overt sign of a more fundamental disturbance, and because a patient suffers from gastric pain, lumbago, tachycardia, or frontal headache it is not, as I am sure you will agree, at all certain that he or she is suffering from organic disease of the stomach or heart or that rheumatism or eyestrain can be accepted as a satisfactory label. Rather are there in countless cases underlying causes which should remove the diagnosis into a totally different category. Dr. Maurice Cassidy, speaking as a consulting cardiologist (Brit. Med. Jour., 1934, i., 45), says that 29·5 per cent. of cases referred to him are psychoneurotic in origin. The symptoms are cardiac but the causative factors lie in the realm of psychological medicine. As with hearts, so I submit with many other things, particularly gastric cases. Further, a patient may have pneumonia or appendicitis or a fractured leg, and may be sick for a number of weeks. Is it statistically correct to label that patient with the original diagnosis for the full run of his or her absence? For the purposes of everyday practice it is, since differentiation is clinically difficult and administratively impossible, but it is not giving us a true picture of the patient's condition so to label it all the time. Most sickness statistics unless accompanied by a full clinical history of each patient can be, and I think are, misleading. We shall never get a true picture of the actual position in regard to the seventeen odd millions of people under N.H.I. We can, however, get accurately assessed samples. We can note significant points in special researches and can draw conclusions within a reasonable margin of error. When we get such an insight into representative samples we find gaps in our judgments of the so-called minor ailments —ailments which for producing inefficiency, unhappiness, and widespread secondary effects far out-distance the more spectacular, less frequent but objectively graver illnesses.

SICK ABSENCE DEPENDENT ON EMOTIONAL ENVIRONMENT

In 1927 the Industrial Fatigue Research Board (M.R.C.) (now the Industrial Health Research Board) began investigations into the various factors which operate within industry and commerce to raise or lower sick absence rates. The clinical and statistical difficulties encountered are set out at length in the various reports of the Board, but the conclusions reached by Prof. Millais Culpin and Dr. May Smith, who with the help of Prof. Major Greenwood carried out the bulk of this work for the Board, point to the fact that, leaving acute upper respiratory tract infections out of the picture, the amount of sick absence in any organisation is affected profoundly by conditions not of physical but of emotional environment. In the twelfth annual report of the Board the following summary is given :—

> "*Although it has not been found possible as yet to isolate in particular cases the causative factors in sickness absenteeism, yet there is evidence to support the hypotheses that a high rate may be expected where the following occur* : (1) rigidity of conditions ; (2) routine work offering few prospects of promotion for intelligent workers; (3) clerical as against productive or organising work; (4) badly selected departmental heads ; (5) anomalies of payment " (p. 25).

Apart from conditions of work and life there is another important factor—namely, the susceptibility of individuals to these conditions. In reviewing large numbers of workers in different occupations, Culpin found that some 50 per cent. of all persons studied—not sick persons but total staff—showed on investigation definite signs of nervous instability and that "there is a tendency for the nervous people to have more sick leave, not necessarily of the type diagnosed as nervous " (Rep. 61, p. 43). Farmer and Chambers (I.H.R.B., 11th Ann. Rep., p. 53) found the same correlation between nervous instability and a high accident rate.

The investigator in this work must have access not only to the documents but to the patients themselves and to their places of employment, and be able to interview large numbers of the staff who do *not* report sick. These are the essential requirements in any survey of the social and economic influences at work on the health of an industrial population. Such results as I personally have obtained, studying a mixed commercial and industrial population of some 17,000 male and female workers over a period of nine years, support in nearly every significant particular the work done by the Board and its investigators.

Apart from seasonal epidemics, sick absence varies *not so much* with occupation as with places of employment. It may vary within wide limits from as low as 2 days per person per annum to as high as 15. The variations are such that firm A and firm B in the same town, engaged in the same type of work and in other ways more or less comparable may present figures more or less steady year by year and yet differing widely between A and B. Large annual variations within a given group are rare but between groups they are common. These rates may, and indeed do, bear little or no relation to those of the general population surrounding them.

CORRELATION WITH LABOUR TURNOVER

If we search for a factor to correlate with the rates of sick absence we find a significant one in labour turnover, and it appears as definite that a high sickness rate and a high labour turnover go together. There are two main exceptions : (1) If a firm automatically dismisses its sick employees then it will have a high labour turnover rate but a low sickness absence rate ; (2) in certain other occupations where labour turnover is low sick absence is relatively high. The explanation in these cases is not so simple. While fatigue, dislike of the work, and general discontent will tend to a high sick absence rate, and while a degree of security is necessary for happiness and health, *complete* security is rather a double-edged weapon. There must, it is true, be the minimum of factors tending to unease a staff if you would keep your sick rate low, but so too there must be no insurmountable obstacles in the way of reasonable change of occupation within the organisation nor to the desire to leave it altogether should the urge arise. If then in a well-run organisation you institute, say, a pension scheme on terms that make severance of connexion inseparable from financial loss, and if too you put people on a set of occupational rails that they cannot leave even for a parallel set during the whole course of their working life, and if further you institute a purely seniority system of promotion you may, and indeed in most cases you do, find a disproportionate amount of sick absence. A condition will have been set up which Culpin has termed "rigidity of occupational conditions" and this, just as much as insecurity, fatigue, and discontent or dislike of the work, leads to increased sick absence. Briefly, an organisation run on enlightened lines will tend to have a low sick absence rate more or less in proportion to the amount of scope available for reasonable ambition and individual effort.

RELATION TO INCENTIVES

Sickness varies too according to the system of incentives incorporated in the payment of wages. It is generally higher for staff employees than for those "on the clock." It goes up along with the accident rate when overtime is worked consistently for long periods. It falls, quite apart from any money incentives, when the department or firm is called upon to make a special effort and tends to rise slightly afterwards if the effort has been prolonged. Short spurts may reduce sick absence without a corresponding rise to follow. I submit that these facts, not in one firm nor in one service but in many firms and covering many thousands of workers, point to some causative agents for much of our sickness which do not yield their secrets to the radiologist, the pathologist, nor to the physician who thinks of a patient isolated from his environment in terms mainly of organic disease. The results of extensive investigations suggest that we are not dealing with physical disease so much as with symptoms of ill-health, not necessarily physical all the time or even fundamentally any of the time. There is a profoundly significant suggestion that much, very much, of it is psychoneurotic in origin, even if its overt form simulates organic disease. I would go so far as to assert that well over half the time lost among the insured population due to ill-health is psychoneurotic. I do not suggest that half the *cases* are of this nature, but half the lost time is, I believe, to be explained mentally rather than physically. The time taken to recover full function even after such a disorder as a fractured radius or a lobar pneumonia depends to an extent, too little recognised, not only on the patient's temperamental make-up but on the emotional background of the home and of the conditions of employment.

Does malingering play an important rôle in producing and prolonging absence from work? Except as an odd case in special circumstances I cannot see what incentive there can possibly be for anyone willingly to forego wages for sickness benefit and risk in addition the possible loss of his or her job. When the time comes for sickness benefit to fall to the level of disablement benefit a large proportion of persons "sign off" and return to work, but that can be better explained along other lines. I suggest two explanations which will cover nearly all such cases. In the first place the patients who make this sudden decision to return to work at the end of 26 weeks are almost invariably cases of frank psychoneurosis or of organic disease or trauma which has passed into a psychoneurotic phase. In the absence of treatment directed towards the solution of their mental problems they hang on hoping to feel better, and finally, faced with no prospect of complete cure by physical means, and finding that they cannot live on their disablement benefit, they choose the lesser of two evils and return to work. Their subsequent history is often one of economic inefficiency lasting many more months. The second explanation is that sympathetic understanding without self-discipline is as detrimental to a patient as hard discipline with no understanding. If either the doctor or the employer is unwise in the giving of indiscriminate sympathy sickness can be indefinitely prolonged and only terminated by economic hardship. Correct diagnosis and appropriate treatment ought to eliminate both these categories. It is not correct, however, to call these people malingerers.

Emotional and Instinctual Reactions

It is necessary to be quite clear that we are discussing a problem in social medicine and that the sincerity of the medical certificate which is given by the doctor in a fiduciary capacity is not being called in question. If any blame is to be attached let it be to a system of medical education which ignores occupational, social, and domestic environments, and emotional and instinctual reactions to them.

The following diagnoses are common—nerves, nervous or general debility, anæmia, and neurasthenia. They are all unfortunate, particularly the last two, for the anæmias generally have normal blood counts and the label of neurasthenia sticks closer than a brother. While many may forget for what a particular abdominal scar once stood, no one ever forgets once he is labelled neurasthenia. It is a highly respectable, sympathy-producing condition. It tends to become a continually recurring excuse for evading life's responsibilities and it should never be hastily nor lightly diagnosed. The bulk of the cases are anxiety states and should be dealt with as such, but the word "neurasthenia" is a very harmful one. The difficulty of fixing the correct label to many of these cases must be admitted because, while a patient may forgive his doctor for misdiagnosing pneumonia as appendicitis, he finds it very hard to forgive him for writing anxiety neurosis or emotional dysfunction on the certificate. Moreover, if the doctor does this it is not long that his patient is left in peace, since bureaucracy still too often regards psychological ill-health as a crime, while very few approved societies admit even the existence of psychotherapy. Patients and officials demand something concrete and physical even if it is wrong, rather than something correct obtained at the price of an abstract diagnosis; but the problem is a very real and urgent one since the patient takes his cue from the written certificate and expects to recover only as a result of treatment directed towards the cure of the stated disease.

The Regius Professor of physic at Cambridge has recently been pleading for a psychological outlook on such disorders, but the lack of a biological outlook in administrative circles is one of the great obstacles; a similar lack in the patient, and especially in his employer, can cause a doctor many difficulties, but if we take a firm stand even approved societies must eventually come into line. Financially they have everything to gain and nothing to lose by doing so. Some have done so already.

It would be impossible for any practitioner to carry out adequate psychotherapy on all the patients who needed it. The time factor would rule such a proposal out of court, but if we regard the sickness problem as largely capable of evaluation in psychological terms we shall have gone a long way towards the solution of one of the economic problems of our time. We are not only concerned with persons who actually incur loss of time and earning capacity, but with an even larger body of people who, though they remain at work, experience times of relative inefficiency, often long and not infrequent.

Modern economic life demands qualities in those who bear its responsibilities, even if in quite a humble sphere, wholly different from the qualities which made for success and efficiency in the premechanical days. Much of the best work in the world, as Dr. J. R. Rees reminds us, is done by neurotics and much of the control of their work is in the hands of people who do not understand this. Moreover, intense competition has produced a tension throughout the whole industrial and commercial structure.

THEIR DIAGNOSIS

I do not think that many of us can lay our hands on all the data necessary for making a diagnosis where the function of organs is impaired by processes other than obvious and demonstrable organic disease. The private doctor knows the home life and often the early childhood and upbringing of his patients, but he cannot know much, if anything, about their working lives unless he is fortunately placed. Where industry has taken upon itself to establish its own medical service the industrial doctor can supply the private practitioner with an entirely new facet of the problem and the two working together do, I think, stand a much better chance of arriving at the correct solution than if each should work in ignorance of the other.

If modern economic development is the foster-parent of psychoneurotic ills it is also the means whereby groups are formed sufficiently large to enable this joint medical enterprise to develop. It should prove of great value in the evolution of preventive or constructive medicine. The doctor attached to a large organisation has as great an opportunity as the general practitioner if he will but use it. He knows a corporate society (for such is a large modern firm) sufficiently well to assist in making the most of each individual's abilities and he can place at the disposal of the private practitioner facts and opinions which are often essential to correct diagnosis. Industrial and private medicine are not competitors but essential allies and co-partners.

It is true that there are only about fifty whole-time industrial doctors in this country, but just as industry and commerce are as vital to healthy living as the schools, so industrial medicine will ultimately spread just as school medicine has done. In the meantime, hosts of small firms would gladly employ the services of a local practitioner for a few hours a week if employers felt that we as a profession were determined to study and grasp the problems of industry and commerce. We ignore these things in our medical education and very few develop interest afterwards. The gulf between the consulting-room and the office, factory and shop is wider and deeper than we care to admit.

AND THEIR TREATMENT

If we concede, as we must, that psychotherapy should only be attempted in its more elaborate forms by competent clinical psychologists, there yet remains a vast amount of work to be done on quite simple lines by such a coöperative partnership as I have mentioned. I refer to that mass of clinical material which, whether at work or on sick leave, suffers from what the patient describes as nerves, depression, anæmia, or even as "just proper run down." It includes cases of cardiac dysfunction, dyspnœa, neuritis, and of aches and pains innumerable. Insomnia, indigestion, and irritability form a very imposing rearguard to a list by no means complete. In my own sphere I see about a thousand such cases a year. That is in an organisation with a low sickness rate, a happy contented staff, and first-class management. Evidence is plentiful as to the widespread nature and importance of these so-called minor ailments and to the extensive unhappiness and misery that they cause. In the bulk of cases there is a disturbance of emotional balance due to causes which may be simple or complex, serious or trivial—i.e., to the observer; for to the patient nothing can be trivial which deprives him or her of the full enjoyment of health and happiness. Perhaps it is the fear that others will regard these things as trivial which causes patients to be so reticent about them. Hence the importance of a highly trained nursing staff in industry to make the necessary contacts and to bring the cases to notice.

We may admit that the seeds of disturbance and maladjustment are laid in early childhood and that occupational factors only act as detonators to a charge already laid but, be that as it may, simple measures will often effect a cure. By cure I mean a sufficient degree of insight on the part of the patient to enable him or her to acquire psychological immunity.

Three Common Types of Disorder

The obsessional, the anxiety, and the hysteric are the three common types and it is to Millais Culpin and May Smith that industry owes a great debt for making us recognise their significance in a highly organised environment.

(1) The obsessional with his unreasoning drive in regard to work, hyperconscientiousness, *sentiment d'incomplétude* of Janet, compulsions, repetitions, and feeling of uncertainty. The patient who must go through work several times (often a fixed number of times) and has the utmost difficulty in leaving a job that he knows to have been quite satisfactorily and conscientiously finished; who dislikes observation and is generally a person of great reliability, thorough rather than brilliant. When he breaks down it is attributed to overwork, whereas the breakdown, and in extreme cases the suicide, are, together with the excessive urge to work, only symptoms of a deeper psychological state.

(2) The anxiety type is apprehensive and often states that when faced by superiors he loses control of his thoughts. The type who may regard all subordinates as constituting a hypercritical judgment on his actions, and who consequently fails in positions of authority or who breaks under the strain of controlling his feelings, who imagines at all times a most improbable worst except, as in some cases quoted by Raymond and Janet, when he knows he has done something worthy of censure. These patients specialise in so-called D.A.H., tachycardia, and epigastric pain.

(3) The hysterical type is largely recruited from Jung's extrovert class who find in physical symptoms their escape from intolerable situations whilst saving their *amour propre* intact. "No, I didn't take that post—you see I had awfully bad luck—I was ill at

the time." Is not that illness the result of being offered promotion to a job which the patient knew he was incapable of filling? Illness is the escape mechanism, for there is no stigma attached to ill-health that is physical; but we cannot yet discuss psychoneurotic ill-health without being accused of imputing insanity or malingering, while hysteria placed on a certificate might result in the patient losing his job, especially at the hands of an employer who happened to be an intolerant extrovert. But in the privacy of the consulting-room the patient can be shown how his physical symptom is an escape. On the whole patients take the suggestion well, and often face life anew. I know many, and they are now doing well in posts which previously they had evaded on the honest but pathological grounds of physical incapacity.

AND THEIR EFFECT IN INDUSTRY

When vested with authority what havoc these maladjusted persons can play with other people's lives. Imagine one of your anxiety type, in a position of control over a number of subordinates, finding compensation in an aggressive or overbearing manner; and how, if given the power and the requisite detonator, which may be quite a trivial matter, he may hold over several people the fear of dismissal; and since the exercise of power by these people is often highly capricious, how devastating the results may be.

Gastric pain and so-called D.A.H. have a high correlation with the anxiety states and are found not only in such superiors as I have just sketched, but in their victims who when even normally balanced in their emotions may easily become pathological with a few months of such treatment. These people exist in fairly considerable numbers, and in large concerns it is vital that no manager should be given power of dismissal that is not subject to review by an independent authority. Power to-day tends to become concentrated in ever fewer hands, and the larger things get and the more "rationalised" they become, the greater is this tendency. Where power in the hands of an emotionally unbalanced person operates unchecked it gives rise to a high labour turnover, a high sick absence rate with an increase of gastric and cardiac cases.

The obsessional type comprises a high proportion of the very efficient, but to work for an emotionally unbalanced obsessional is to experience the fringe of Dante's inferno, especially if he cannot bear to delegate responsibility and must be kept informed about every detail, which he criticises with meticulous care. Unfortunately he often earns from his superiors a wholly unwarranted reputation for being indispensable.

The economic factors which touch up people's varying temperaments differ greatly. Some are content with everything except perhaps the foreman, others look out upon this complexity of engineering, economic and administrative machinery, and wonder whether they count for very much. They tend to regard themselves as cogs in the mechanism and develop, maybe, into malcontents, maybe into patients. The man who is unemployed may rage openly at the street corner or symbolically in the sick-room at the machinery which he regards as his enemy, while the ambitious lad from school may lose his interest in work or develop into a clinical or criminal problem.

There are countless factors in industry and commerce to-day which give rise to clinical problems calling for much coöperation between medical practitioners and those engaged administratively. The most valuable help about such cases can be obtained by making study of conditions of work in the firms which employ your patients, and the emotional is more important than the physical background. Of course excessive hours, bad ventilation, and undue strain must be corrected, but once these things are put right, it is the psychological environment that needs elucidation.

Prevention Easier than Cure

Psychological disorder is easier to prevent than to cure, and hence our educational system must aim at fitting children for life as it will probably be lived thirty years ahead rather than as it was thirty years ago. No person, in my opinion, should hold any position of authority over human beings in industry or commerce who has not had a sufficiently broad biological outlook inculcated as shall enable him or her to understand the place of instinct and emotion in human life and temperament. This educational reform is, I believe, at the root of constructive social hygiene in the future. In the day continuation school attached to my own firm we have, with the approval of the Board of Education, instituted elementary general biological training as a cultural subject, and I have great hopes of its development and value but it is as yet in its infancy. It has demonstrated that few children from the schools to-day have the vaguest idea of the place of man in the scheme of things, no knowledge of the romance of human development, and little innate urge towards physical and mental integration. It is possible to obtain this even after the age of 14, but it should be begun very early if it is to bear the best fruit. We must not, however, confuse the creation of thousands of half-baked biologists, which would be futile, with the basic need for a general and cultural biological outlook, which is essential.

Economic development is evolving towards a high degree of organisation and interdependence, and medicine is slowly but surely finding its place in this structure. We must not condemn rationalisation and high-grade organisation, for it appears to be a necessity of survival in a mechanical and scientific age, but we must integrate the new developments with our medical policy.

Correlated medical services in school, industry, commerce, and home must be evolved within an economic scheme which has for better or for worse become organised and rationalised on a vast scale. The fact that much work is still done by small-scale methods does not in the least detract from the argument. The troubles attributed to modern industrial and commercial methods are more than likely to be but the troubles of a phase of transition, but if they are to pass we need to have a people more mentally and physically integrated than we have at present, more psychologically adult and more determined to be masters of their own destinies. Medicine has an enormous new rôle to play in education, constructive planning, and in therapy. Much more interest must be taken in coöperation with educationists and with the leaders of industry and commerce in the evolution of training and of methods of employment. While as regards treatment much can be done within industry in such a way as to interfere as little as possible with production and earning capacity.

I hope we shall not let our opportunities slip away in any mistaken belief that modern economic tendencies are of no real or abiding significance to the practice of medicine in its fullest sense.

THE ADRENOGENITAL SYNDROME*

By L. R. Broster, O.B.E., M.Ch. Oxon., F.R.C.S. Eng.

SURGEON TO CHARING CROSS HOSPITAL, LONDON

The occasional occurrence of secondary male sex characters in the female has long been known, but remarkable advances have been made since 1905 when Bulloch and Sequeira [1] first brought into prominence the relation between the precocious appearance of secondary sex characters and the presence of cortical tumours of the adrenal. My interest in the condition was first stimulated some eight years ago by my colleague, Dr. Gordon Holmes, who asked me to remove the adrenal from an adult with similar symptoms. A few cases had already been reported in which tumours, both simple and malignant, had been surgically removed as a remedy for the syndrome, but its association with cortical hyperplasia had not then been recorded except in the post-mortem room. Dr. Gordon Holmes's case proved on laparotomy to belong to the hyperplastic variety, so we ventured to remove the larger adrenal. It was the forerunner of the present series of cases.

The condition has been described in detail in three previous publications,[2-4] and I propose here to deal with it in a more general way, mainly from the biological point of view.

Clinical Features

The syndrome may be defined as that condition in which secondary male sex characters appear in the female, and it is associated with a retrogression of the primary and secondary feminine characters and their functions. The main changes, which depend upon the time of onset, may be briefly described as follows. (1) The appearance and disappearance in the female of hair according to the male pattern and distribution. (2) Alterations and bodily contour towards the male sphere: broadening of the shoulders relative to the pelvis; overgrowth of muscle and bone, lessening of the subcutaneous fat, and a coarsening in the texture of the skin; enlargement of the clitoris; and deepening of the voice. (3) Immature development of the female genitalia, both internal and external; absence or under-development of breasts; degenerative changes in the ovaries giving rise to amenorrhœa, either primary or secondary, or disturbances of menstruation. (4) Alterations in the psychological outlook towards the male type.

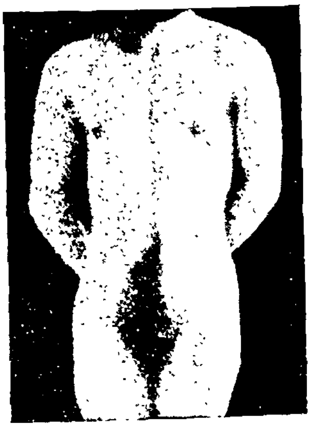

FIG. 1.—Group I. Case 2 of summary.

As the numbers in the series increased, it became possible, in 1932, with the coöperation of Dr. Gardiner-Hill and Dr. Greenfield, to publish a paper [5] in which the cases could be classified into three groups:—

I.—Adrenal pseudohermaphroditism, in which the changes were declared at puberty, and were accompanied by primary amenorrhœa.

II.—Adrenal virilism, in which the changes appeared after a normal puberty, and were followed by disturbances in the menstrual function or secondary amenorrhœa.

III.—Mild virilism in association with other endocrine disturbances occurring after puberty—the fat type.

Since then I have been able to add a fourth group—post-menopausal virilism.

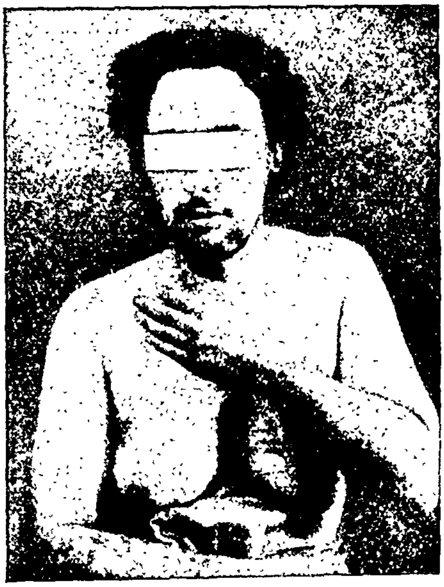

FIG. 2.—Group II. Case 11 of summary.

Group I.—It will be seen from the accompanying illustrations that the earlier the onset the greater the degree of virilism. There is obviously a masculinising factor at work, and if it starts at some time before puberty, when active bodily growth and sexual development takes place, it will change the figure of a woman to that of a muscular man. In the patient shown in Fig. 1 there is much hair of male distribution, the clitoris is enlarged, and the feminine characters have dwindled. The uterus is infantile, the ovaries are cystic, the patient has never menstruated, and she has no breasts.

Group II.—Most of our cases belong to this group in which changes are not so well developed. Here the onset of virilism is after puberty, and averages from 15 to 18 years in the series. Menstruation starts normally, but at the time of onset of the virilism, or soon after, there is an upset of its normal rhythm and duration, and secondary amenorrhœa may supervene. The uterus is small and the ovaries degenerate. There are other signs of endocrine imbalance at this stage; some of these patients become fat, and while the majority lose this fat and remain adrenal in type, others retain it and drift off into multiglandular types. The male build and male distribution of hair are well marked in the illustration of this group. (Fig. 2.)

Group III.—The case illustrating this group (Fig. 3) is anomalous in that the male element, as shown by abnormal hair and enlarged clitoris, is not marked; the infantile uterus, cystic ovaries, and amenorrhœa conform to type; but a third element has crept in, as shown by the abnormal deposition of fat. This increase in weight dated from the onset of virilism and the cessation of the menses at the age of 16. This particular case has been previously published, and Dr. Gardiner-Hill considered that the adrenal formed part of a multiglandular syndrome; since then, however, he has inclined to the view that the case is probably one of Cushing's basophil adenoma of the pituitary.[5] The differences in this group from the others will be alluded to under the various headings, but at any rate it gave us a valuable hint of an association between the adrenal and pituitary. Intense headaches of the migrainous type with fits of depression are common in these cases, and the possibility of their being of pituitary origin must be considered.

---

* A Hunterian lecture delivered before the Royal College of Surgeons of England on Jan. 19th.

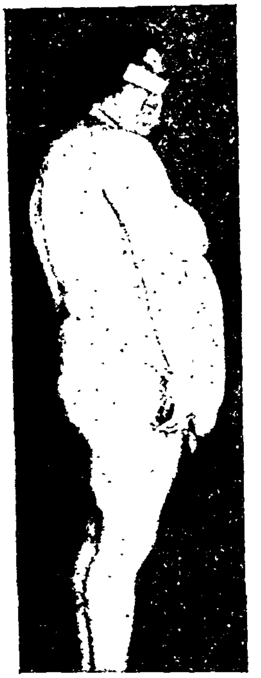

FIG. 3.—Group III. Not operated upon. Similar to Case 3 of series.

Operative Results

In a series of 15 cases, summarised in the accompanying Table, our experience of the effect of unilateral adrenalectomy on the main symptoms has been very gratifying in Group II., but not in Groups I. and III. There has been a fairly uniform disappearance of the male characters, and a quicker restoration of the feminine functions. It will be seen that the adrenals have been removed from one or other side, so it is natural to infer that they are both involved in the pathological process. The smallest of the glands excised was within the normal limits, yet the clinical result was very satisfactory. Thus we have been able to establish the important fact that virilism is independent of the size or hypertrophy of the adrenal.

In Group II., as already stated, the average age of the onset of virilism is 18 to 20, after a normal puberty, so the syndrome has developed in the comparatively short space of four years, and has not become too fixed. The removal of one adrenal, usually the larger, has been sufficient to swing the balance from the male towards the female sphere. The main features of recovery are the shedding of hair and the return to normal menstruation. The acquired hair can be pulled out in bunches, with little or no pain, within a few days of the operation. In some patients the hair becomes white at the tips, and in others a slight sex colour differentiation has appeared. The subject of hair is a delicate problem with women. With virilism they will adopt any alternative rather than shave, and after adrenalectomy they are equally unwilling to pull this hair out.

The menses show a gratifying return to normal, even after prolonged periods of amenorrhœa, and the injection of œstrin has been of considerable value in the more obstinate cases. In one recent case operation was followed by a complete depilation of male hair within a fortnight, and a period within three days after seven years' amenorrhœa. There is as yet no apparent injury to their general health; their complexions become rosy, their minds are happy, and in some of the cases with the reappearance of feminine functions there has been a return to the finer points of feminine interest.

In Group I. operation after puberty is far too late to have any chance of changing characters which have become fixed. If it were possible to diagnose virilism before this date, then earlier operation should have equally good results. The problems of Group III. will be discussed later.

The operation is a difficult one, and demands a technique and care of its own. I feel it has been justified by the contribution it has made to research. There is at present only one indication for operation—namely, that the case belongs to Group II., and it is to be hoped that operation on other types will be undertaken only with the genuine idea of making additions to knowledge.

Laboratory Investigations

The laboratory investigations undertaken have been: first, chemical and metabolic (in which I have had the help and advice of my colleague, Mr. Jocelyn Patterson, Ph.D., and of Mr. J. Adler); and, secondly, histological.

In the chemical and metabolic investigations we have travelled hopefully on a long road but have failed to arrive at any very definite results. We have examined the blood calcium, phosphorus, cholesterol, and urea, the gastric juice, the blood-sugar, the sugar-tolerance curves, and the effect of insulin on the fasting patient. This last experiment was designed to see what resistance the patients had to insulin, and the blood was examined at half-hourly intervals. All these tests were within normal limits, except for slight differences in the cholesterol and sugar metabolism. The blood cholesterol was definitely raised in Group III. cases. The sugar-tolerance curves in most of the cases showed some distortion from the strictly normal response, in that there was a normal elevation from the fasting stage, but a slower return to normal. The majority of curves came out on the high side, making the average above normal, and the highest were of the Group III. type. The insulin test was generally unsatisfactory from the point of view of drawing any conclusions, but as a whole there was a tendency to show a resistance to insulin. The immediate result of operation on the sugar-tolerance curves was negligible, and in one remote result, also Group III., there was a further decrease in the sugar tolerance. (Fig. 4.) In the few cases of the Group III. type, there was a definite increase in the red cell count. From these results it will be seen that the main differences from normal standards

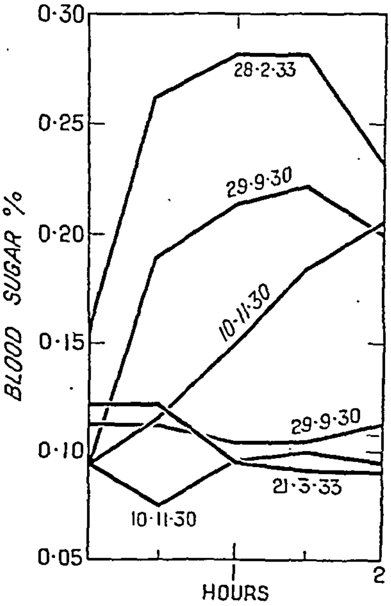

FIG. 4.—Sugar-tolerance curves from a case of Cushing's syndrome submitted to unilateral adrenalectomy. The three upper curves represent the sugar-tolerance curve taken before, immediately after, and some time after operation. The lower curves represent the sugar-tolerance curve after the administration of 10 units of insulin.

SUMMARY OF CASES

Group.	Age.	Date of operation.	Degree of virility.	Hair.	Periods.	(a) Voice. (b) Breasts.	Outlook.	Genitalia.	Clitoris.	Fuchsin reaction.	Result.
I.	15	Sept., 1927.	+ + +	Marked.	Prim. amen.	(a) Low. (b) Under-developed.	Normal.	Ut. inf.	+ + +	Left strong.	Very slight change. Abroad.

II.	30	April, 1933.	+ + +	Marked.	Regular.	(a) Deep. (b) Smallish	Normal.	Ut. small. Fibrous O.	+	Left fairly marked.	Good. Hairs white at ends, pull out easily. Periods regular. Complexion imp.
II.	35	May, 1933.	+ +	Fairly marked.	Amen. at 26.	(a) Deep. (b) Smaller.	Male tendencies.	Ut. small. Big C.O.	+	Left strong.	Amenorrhœa continues. Brighter outlook. Much the same. Fair.
II.†	32	Nov., 1933.	+ +	Marked.	Regular, ceased 26.	(b) Small.	Normal.	Small fibroid in ut., small C.O.	+ +	Left fairly marked.	Period started two days after operation. Hair all out in two weeks. Very good.
II.	26	Aug., 1933.	+ +	Fairly marked.	Irreg. Ceased 20.	(b) Smallish.	Homosexual.	Ut. inf. C.O.	. .	Left mod.	Hair coming out. Periods regular. Outlook brighter and more normal. Very good.
IV.†	54	Oct., 1933.	+	Marked. Bald.	Hyst. R. ovariot. 38.	(a) Roughish. (b) Normal.	Disgusted with herself. Sensitive.	Remaining left ovary cystic.	+ +	,,	Hair all out in two weeks. Slight growth on head. Very good.

* Married since operation. † Married. Prim. amen. = Primary amenorrhœa. Ut. inf. = Uterus infantile. C.O. = Cystic ovaries.

affect Group III. as regards sugar tolerance, cholesterol, and blood count.

In examining the histological material, I was fortunate again in enlisting the help of my colleague at Charing Cross Hospital, Dr. H. W. C. Vines. We argued that if there was no cause to be found in the arrangement or shape of the cortical cells, there might possibly be a difference in function, and by using the Ponceau fuchsin stain he was soon able to show that in all my cases of unilateral adrenalectomy the cytoplasm of the cells of the cortex contained a vivid red granular material, mainly in the inner and middle zones. This colour varied in intensity, and was most vivid in the adrenal already shown, which in size was within normal limits, suggesting that the response was as much qualitative as it was quantitative in the cases of hyperplasia.

To exclude the possibility of post-mortem changes taking place in the adrenal, a further control series was started by removing portions of normal adrenal in the course of performing kidney operations. These were all negative to the stain, as were all normal post-mortem adrenals. We were able to collect from colleagues several autopsy specimens of tumour associated with virilism, and these were positive, showing that the fuchsinophil material in the cells is capable of surviving post-mortem conditions. Interesting as this discovery was, it seemed unlikely that we had hit upon some isolated reaction in the adult, so a further search was made into the fœtus. Dr. Vines obtained a strong fuchsinophil reaction in the male fœtus between the ninth and seventeenth week; while in the female fœtus the reaction was not so strong, and of shorter duration, lasting from the eleventh to the fourteenth week. After the twentieth week it was absent in both sexes. This observation may well prove to be one of fundamental importance in the elucidation of many difficulties. It establishes a very early and passing phase in the embryo, common to both sexes but less marked and of shorter duration in the female.

In the other tissues of the body traces of this reaction were found in the interstitial cells of the testis, the corpus luteum, and the anterior lobe of the pituitary.

Anatomy and Embryology of the Adrenal Gland

In order to give a clear idea of the background of our work, it is necessary to refer briefly to the comparative anatomy of the adrenal, and to trace the steps which have led to the formation of this highly specialised organ.

In its primitive form the cortex is separate and intimately connected with the reproductive system. It then becomes associated with the cells of quite a different system—the sympathetic—which ultimately forms the medulla. It appears first in fishes, and then increases in importance, so that it becomes essential to life in the higher animals. In sharks and rays the two cell-systems are separate; the cortex is known as the interrenal body and is associated with a marked development of the sexual system. In amphibians (frogs) the two cell-systems make a definite advance towards each other, and are arranged in a chain along the dorsal segments, until we find them intimately mixed in reptiles and birds to form a solid organ. In mammals and man the medulla becomes completely enclosed with the cortex, and the method by which these sympathetic cells wander into the cortex in man has not been observed even in the higher apes. From the nature of such a migratory process it is not uncommon for cells to become detached, and to form accessory adrenals, which may contain the elements of one or the other, or of both these cell-systems.

In man the adrenals are situated over the upper poles of the kidneys, and at birth reach the maximum size of their development, when each is about one-third the size of the kidney. The cortex then undergoes an astonishing and rapid process of absorption and regeneration until the size of the gland is reduced to one-thirtieth of that of the kidney. The glands enlarge at puberty, during pregnancy and the menses. Between the fourth and fifth decade they reach their zenith and then gradually undergo a senile involution. It occasionally happens that this adult stage of the gland is present at birth, in which case the fœtus is born a brainless monster, so that it has been thought that the cortex is in some way connected with the development of tissues rich in lecithin.

In point of time the cells of the adrenal cortex can be recognised about the fourth week, and are derived from the same mass of cells—the genital ridge—which also give rise to either the testis or ovary. There is thus a common origin for the cortex and sex gland. The determination of sex takes place about the seventh week, and, as we have noted, the appearance of the fuchsinophil reaction commences some two to four weeks later.

Our clinical evidence and operative results have established a very marked connexion between this reaction and a condition of maleness in the female, and this naturally suggested the possibility that "the substance so staining must be closely related to or even identical with the male hormone or its precursor," [6] while its presence in the intercellular spaces further suggested that it acts via the blood stream.

Crew [7] states that "so far as is known, the sex chromosome mechanism is the sex determining mechanism, but in many cases this mechanism can be overridden and the sex of the individual determined in other ways." It is therefore reasonable to argue that a strong and prolonged male phase in the female fœtus may possibly be one of those factors which so determine sex; to what extent is still a matter of conjecture. Dr. Vines has obtained a positive reaction in true hermaphroditism, and it is probable that sex reversal, from female to male, will come to be included in this category. But we do know that the cells of the adrenal cortex retain the power of developing this substance into adult life, and that it may become activated at certain periods of physiological stress, such as puberty. If we accept this explanation then it readily accounts for Groups I. and II., which we have already considered clinically.

However, Group III. warns us that the problem is not so simple as this. It may be argued that in adult virilism there is a failure on the part of some feminising influence to counteract the male phase. The brief duration of this male phase in the female fœtus suggests that it is suppressed, and this suppression is due to some mechanism dependent on the functional activity of the other endocrine organs. That there is some such mechanism was found by Dr. Vines in two female fœtuses, in which a prolonged male phase was accompanied by a definite hyperplasia of the pituitary. Hence virilism may be due to a failure to maintain the normal balance between the anterior lobe of the pituitary and the male adrenal. This type would be associated with a pituitary dysfunction, the clinical picture being determined by the predominance of one or the other factor, and when the pituitary dysfunction is in the ascendent there is a shift towards the type of basophil adenoma of the pituitary described by Cushing.

Clinical Conclusions

From an examination of some 60 cases with virilism of varying degree, a few general conclusions may be drawn.

That heredity plays a part there is no doubt. A family history of hirsutism was present in a quarter of the cases, and in these it was twice as common on the distaff side. On the male side it ranged from grandfather, father, to brothers; on the female, from mother, sisters, aunts, daughters, and nieces—more frequent in aunts and sisters. It thus appears to be transmitted more on the female side. There is slight evidence that the condition is associated with the events which occur at birth. It occurred in two cases of twin births, one case of premature birth, and in one case in a four-year-old daughter within three months of its onset in her mother. With regard to other endocrine disturbances, it appeared in two patients whose mothers suffered from Graves's disease, in one from whose mother I removed a parenchymatous goitre, and in one whose mother suffered from diabetes. In one case of mild virilism there were symptoms of hyperthyroidism. One point of practical importance must be stressed, and that is women with virilism are comparatively infertile, as one would expect from the nature of the pathology. If they conceive they are apt to miscarry. On the other side, one of my early patients who had amenorrhœa before adrenalectomy, has since married and produced a son.

The syndrome does not appear to be recognised by gynæcologists. In this series one patient had been curretted, and two patients had had hysterectomy, one of them with unilateral ovariectomy. From the nature of the pathology described such interference is only likely to aggravate the condition of virilism.

General Discussion

So far we have discussed the problem only in its more extreme form. The study of the whole series of cases suggests that the adrenogenital syndrome is not a disease but is a definite deviation from the normal evolutionary process. In this respect we have to think in terms of a normal and transient phase in fœtal physiology, which by its persistence gives rise to the abnormal in the adult. I believe it forms a very definite streak in the human species and some of its minor stigmata are fairly common. Nor is it confined to our species alone. We have observed a similar syndrome with a similar pathology in the adult hen. These sex changes are more common in some of the lower animals, who should afford ideal material for research.

If our suggestion of the male hormone proves correct further considerations become apparent. It corroborates the theory of bisexualism, at any rate so far as the female is concerned—a theory whose truth has frequently been assumed but remains unproved. The altered sex outlook which has been observed in these patients, and which reverts to the normal after operation, raises the question of an endocrine basis for certain types of mental abnormality, and this will have to be taken into consideration in adjudicating on medico-legal affairs. The question of heredity has already been referred to, but it is to the eugenist that the problem offers a wide field of research. The presence of the adrenogenital syndrome in man is a retrograde movement, since it tends towards the intersex type. Is it stationary, receding, or increasing? If the latter, then we may be the innocent spectators of an evolutionary process drifting slowly and inevitably into the neuter state. The conditions of life are rapidly changing. The emancipation of women has been a big change; there is over-population in many parts of the world; there are many factors in our social lives leading to race deterioration, and they must react on the individual. Too many minds, content with their lot and unaware of these abnormalities in others, decry this so-called tampering with nature. Theirs is a selfish attitude; but in clinical science there is a spirit of altruism which aims at projecting our acquisitions to the betterment of the human race.

HOSPITALS FOR WOMEN AND CHILDREN.—Last year the South London Hospital for Women and Children, of 140 beds, 25 of them in private rooms, admitted 2518 women and children, while out-patients made more than 69,000 attendances. The cost of maintenance during the current year is estimated at £25,000, and a further £2000 is needed for laying new floors in the wards.—In 1933 the Princess Elizabeth Hospital for Children at Shadwell had 1797 in-patients and 14,689 out-patients, the latter a large increase. The Bailey Convalescent Home at Bognor received 324 patients, and the result of the year's working was a reduction of the bank loan by £2000. Proposals are in hand for the extension of this hospital, which has become seriously inadequate, at a cost of £37,000, of which only £10,000 is at present available.—Owing to the closing of the institution for two months while the out-patient's department was being enlarged, and other improvements made, Paddington Green Children's Hospital last year received only 713 in-patients as against 845 in 1932. Their average stay was 15·13 days and their average weekly cost £3 19s. 1d. Patients paid £626 towards the total expenditure of £11,766.

THE LYSIS OF FIBRIN BY STREPTOCOCCI:

ITS APPLICATION TO THE PROBLEMS OF RHEUMATIC INFECTION IN CHILDREN

BY GEOFFREY HADFIELD, M.D., F.R.C.P. Lond.
PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF BRISTOL

VINCENT MAGEE, M.B., B.Sc. Belf., D.P.H.
DEMONSTRATOR OF PATHOLOGY IN THE UNIVERSITY; AND

PHYSICIAN TO THE WINFORD ORTHOPÆDIC HOSPITAL; ASSISTANT PHYSICIAN TO THE GENERAL HOSPITAL, BRISTOL; COLSTON RESEARCH FELLOW IN THE UNIVERSITY CENTRE OF CARDIAC RESEARCH, BRISTOL

IN 1933 Tillett and Garner, of the Johns Hopkins University, showed that the filtrates of young broth cultures of hæmolytic streptococci of human origin are capable after a remarkably short period of incubation of completely liquefying human fibrin, and in this respect appear to be unique amongst pathogenic bacteria of clinical importance. Animal fibrin proved totally resistant to liquefaction unless produced by the action of human thrombin on animal fibrinogen, and of 18 strains of hæmolytic streptococci of animal origin only 3 were fibrinolytic to human fibrin.

These results may explain the power of hæmolytic streptococci to invade human, as opposed to animal, tissues and throw some light on the anomalous results which have followed attempts to reproduce human streptococcal disease in such animals as the rabbit whose fibrin is totally resistant to streptococcal fibrinolysis. They certainly open up a new line of investigation into the problem of streptococcal immunity.

In their first paper Tillett and Garner showed that when recent and fairly remote streptococcal infection could be excluded, all specimens of human fibrin were susceptible to fibrinolysis, whereas the fibrin from cases recently recovered from such infection often proved totally resistant. They considered this phenomenon of "resistance" might ultimately prove to be a specific response to streptococcal infection due to the development of specific antifibrinolysins analogous to the specific antihæmolysins which are known to be produced against streptococcal hæmolysin (Todd, 1932).

They have recently published another paper with Thomas (1934) in which this opinion is considerably strengthened. Total resistance was found regularly to follow hæmolytic streptococcal infections such as erysipelas, scarlet fever, and streptococcal tonsillitis, but usually not until convalescence was established. It was not found associated with infection by any other micro-organism. In erysipelas "resistance" developed shortly after the temperature fell and persisted for several months. In scarlet fever it was delayed for three to four weeks and persisted for a few weeks only. Purulent streptococcal complications hastened the onset of resistance.

Total resistance to streptococcal fibrinolysis is certainly a remarkable phenomenon; it is always associated with recovery, and, whilst it may be premature to regard it as a specific immunity response, the evidence points in no uncertain way in that direction.

Bacteriological Investigations

We have tested the susceptibility to fibrinolysis of 130 samples of human plasma and the fibrinolytic power of 30 strains of streptococci showing β-hæmolysis on blood plates, and have confirmed the main conclusion arrived at by Tillett and Garner (1933), and Tillett, Thomas, and Garner (1934).

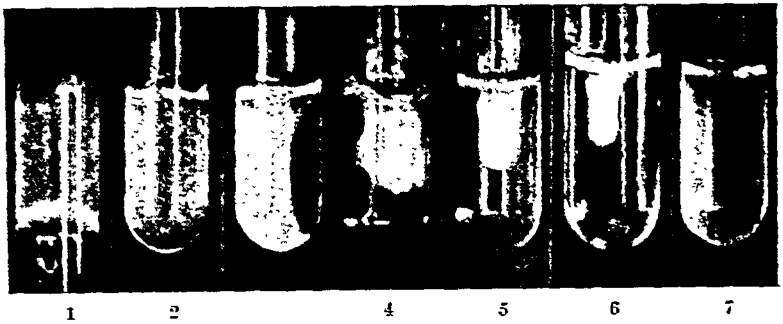

FIG. 1.—Streptococcal fibrinolysis. 1. Clotted plasma. 2–7 stages in liquefaction of clot, which took 28 minutes.

We have used the original technique of Tillett and Garner with slight modifications. Blood was obtained by vein puncture and collected over potassium oxalate (0·02 g. to 10 c.cm. of blood) in centrifuge tubes and tested within 24 hours of collection. The streptococci were grown in buffered meat-infusion broth for 18 hours and the reaction, which was usually in the region of pH 6·0, was brought to pH 7·2 by means of a phosphate buffer solution. To 0·2 c.cm. of plasma diluted with 0·8 c.cm. normal saline was added 0·5 c.cm. of broth culture and 0·25 c.cm. of a 0·25 per cent. solution of calcium chloride solution in saline and the mixture incubated in a water bath at 37° C.

In from 8 to 12 minutes a firm solid coagulum forms and the tube can be inverted without the loss of more than a drop or two of fluid. Incubation is continued, if necessary, for 24 hours. With many normal plasmas complete lysis of the clot takes place in 12 to 25 minutes, and the large majority are completely liquefied under an hour provided a powerfully lytic strain of coccus is used (Fig. 1). Exceptionally complete liquefaction is delayed for four hours. On complete lysis the fluid becomes turbid, the turbidity depending on its original fibrin content, and has a finely granular appearance; all trace of clot disappears. If partially resistant, lysis is delayed for varying periods up to 24 hours, by which time it may be complete or there may still be light or heavy flakes of fibrin floating in an opaque fluid; formed clot is absent. When totally resistant, the clot may have shrunk slightly at the end of 24 hours, there is little change in its appearance or consistency, and the little fluid in which it is suspended remains water-clear.

In all our tests we have used at least three strains of lytic streptococci and at least one, usually several, susceptible plasmas as controls. This is a necessary precaution.

Occasionally an unexplained "lag" occurs in liquefaction even of normal plasma clots. This appears to be due to some change in the culture consequent upon repeated subcultivation, as it is rarely found with freshly isolated and strongly lytic strains. It sometimes corresponds, in a culture originally containing "matt" colonies and their "glossy" variants, to degradation into a "pure glossy" growth, but this can neither be the whole nor the usual explanation as the delay, which may amount to 1½ or 2 hours, may occur when this change is absent. We have found, however, that incubation of the digest at 52° C., after the formation of a firm clot has taken place at 37°, will often hasten lysis.

VARIATION IN FIBRINOLYTIC POWER

We have found that hæmolytic streptococci vary very considerably in their power to liquefy a normal plasma clot. They fall fairly accurately into three groups: the first in which fibrinolysis is rapid and complete; the second in which it is slower but eventually, in approximately double the time taken by cultures in the first group, the clot is completely digested; and a third in which lysis is slow and still incomplete at the end of 24 hours.

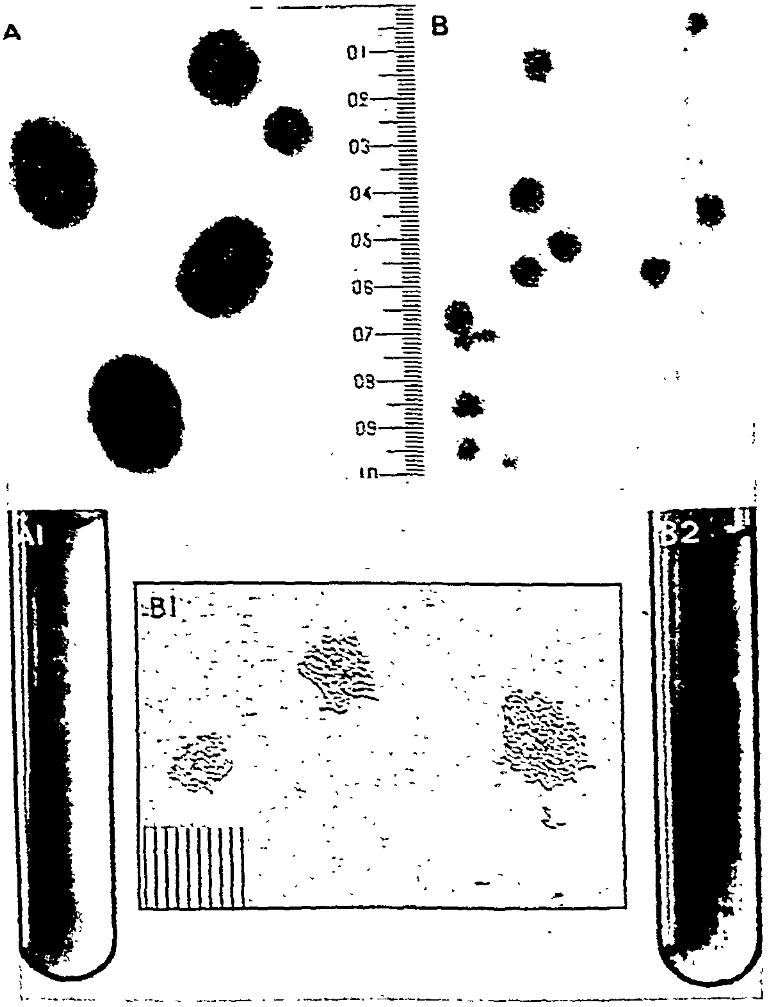

FIG. 2.—A. "Glossy" colonies magnified 64 diameters; (24 hours' growth). A1. Broth culture of A which had little or no fibrinolytic action. B. "Matt" colonies magnified 64 diameters; (20 hours' growth). Scale is 1 mm., graduated in tenths and hundredths, magnified to the same degree as A and B. B2. Broth colonies of B which were powerfully fibrinolytic. B1. Young "matt" colonies of a powerfully fibrinolytic strain magnified about 285 diameters; (6 hours' growth). Each division of the scale represents a two-hundredth of a millimetre.

Our strains were distributed amongst these groups as follows :—

Group I.—(5 strains)

	Strains
Scarlet fever with purpura	2
Scarlet fever	1
Fatal puerperal septicæmia	2

Group II.—(6 strains)

Fatal puerperal septicæmia	1
Fatal general peritonitis	1
Impetigo	1
Streptotoccal tonsillitis	3

Group III.—(19 strains)

Scarlet fever	8
Streptococcal tonsillitis	5
Subacute rheumatism (children)	4
Tooth socket	1
Udder of streptococcal mastitis (cow)	1

All strains were tested for acid production and their capacity to hydrolyse sodium hippurate. By this method one apparently bovine strain was found in Group III. in addition to the strain known to be of bovine origin. All other strains were regarded as being of human origin.

This grouping suggests that fibrinolysis is an attribute of those streptococci which produce severe human infection. None of the strains in Group III. were from cases suffering from a general or a severe infection. The majority of those in Groups I. and II. were from such cases. Our numbers are obviously too small to justify a definite opinion on this point, but they were suggestive enough to encourage further inquiry in this direction.

Except with one strain from a case of fatal puerperal septicæmia of a few days' duration we found that all cocci in Groups I. and II. produced a granular deposit in broth without general turbidity and their colonies were "rough" or "matt." Of the 11 strains in these two groups 4 produced "bread-crumb" colonies which were small, had a very irregular edge and a "matt" surface (Fig. 2). When examined at a magnification of about 400 diameters before becoming visible to the naked eye these colonies were seen to consist of a few extremely long chains very loosely coiled together and throwing out loops at the edge, which thus appeared irregular (Fig 2). This "matt" appearance was present but not so well developed in all the remaining strains except one in these two groups. The exception had the colonial characters of the cocci in Group III. These were, without exception, of the glossy or smooth variety with a "porcelain" surface and a sharp edge; their microscopic colonies were composed of tightly packed short chains; there was no looping at the edges.

Although it is doubtful if "roughness" and "smoothness" amongst streptococci is the same phenomenon as the similar variation found among other bacterial races, "roughness" in streptococci is usually regarded as being closely associated with virulence. That, with one exception, all our most powerfully fibrinolytic strains were rough strengthens the impression gained by studying their source that fibrinolysis and virulence to man may prove to be closely related.

Further support for this view is given by the results of virulence tests which were applied to the majority of the cocci of each group. Quantities varying from 0·5 to 0·0001 c.cm. of young broth cultures were injected intraperitoneally into mice, uniform distribution of cocci being obtained by centrifugalisation and suspending the deposited cocci in distilled water. Four strains tested for virulence in Group I. gave an average minimum lethal dose of 1/2000 c.cm., the average lethal dose of 3 strains in Group II. was 1/50 c.cm., while of 5 strains from Group III., 0·5 c.cm. of four of these failed to kill mice in four days and one was fatal in this dose only in five days.

A complete investigation of the carbohydrate reactions of all strains revealed no reaction or group of reactions which could be correlated with the grouping described above based on fibrinolytic power except that, as a general rule, the final acidity after four days' incubation in 1 per cent. glucose was greater in the feebly fibrinolytic Group III. than in the other groups. (Average for Groups I. and II., pH 6·1, for Group III., pH 5·0.)

After our primary growths had been subcultured about ten times, it was noticed that several of the strains in Group II. were losing their fibrinolytic power and their broth cultures were becoming turbid. We therefore retested the majority of our strains against normal plasma clots after about 30 subcultures had been made. Two strains originally in Group I., both originally isolated from cases of scarlet fever, and both originally producing "pure matt" growths on nasgar were found to be growing in "pure glossy" form and had lost almost all their fibrinolytic power. Three strains, originally in Group II., all isolated from cases of streptococcal sore-throats, had undergone a similar degradation. Of our 11 actively fibrinolytic strains, therefore, fibrinolysis appeared to be a relatively permanent characteristic in 6.

No exact correlation could be established between hæmolysin production and fibrinolysin production. It was a general rule that strongly fibrinolytic strains were also strongly hæmolytic as judged by their effect in the usual dilutions after one hour's incubation with a constant dose of sheep's red cells; 4 weakly fibrinolytic strains however were found to produce relatively large amounts of hæmolysin.

RELATION OF FIBRINOLYSIS TO FIBRIN CONTENT

If fibrinolysis is not a specific attribute of hæmolytic streptococci, susceptibility to lysis should be related to a low, and resistance to a high, fibrin content of the clot. The fibrin content of 60 specimens of blood was determined by removing and washing the clot from a known volume of plasma and accurately weighing it after drying to constant weight.

The figures obtained are shown in Table I. :—

TABLE I

Fibrin content. (Mg. per 100 c.cm.)	Cases in which plasma clot was—		
	Completely dissolved.	Partly dissolved.	Totally resistant.
Between 300 and 400	8	1	..
" 400 " 500	24	2	..
" 500 " 600	9	0	..
" 600 " 700	3	3	2
" 700 " 800	2	1	..
" 800 " 900	1	..	1
" 900 " 1000	1	..	..
" 1000 " 1100	0	..	..
" 1100 " 1200	1	..	..
" 1200 " 1300	0	..	..
" 1300 " 1400	1	..	..

Included in the first group is a case of pneumococcal lobar pneumonia whose plasma contained 1400 mg. of fibrin per 100 c.cm. This exceptionally heavy clot was completely digested in 25 minutes by a streptococcal culture. Another case in which the fibrin content was 830 mg. per cent. and the plasma clot completely lysed, was proved to be suffering from acute streptococcal septicæmia following lateral sinus thrombosis, and the coccus identified as belonging to the viridans group. In contrast with these cases the plasma clots from two cases of hæmolytic streptococcal infection proved totally resistant to the lytic action of powerfully lytic strains, although their fibrin content was between 600 and 700.

We feel justified in concluding, therefore, that susceptibility and resistance to fibrinolysis is in no way related to the fibrin content of the plasma, a conclusion which lends strong support to the view that digestion of the plasma clot is a specific effect, and resistance to fibrinolysis a specific immunity response.

Resistance to Fibrinolysis in Rheumatic Infection

As a certain amount of evidence has recently accumulated which suggests that hæmolytic streptococci play an important rôle in the production of rheumatic infection in children, we investigated the plasma of 44 children suffering from rheumatic heart disease for resistance to fibrinolysis.

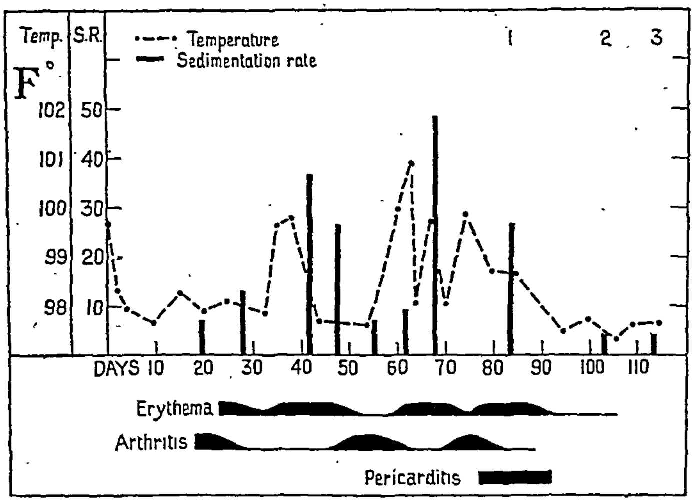

FIG. 4 (Case 2).—Changes in temperature and sedimentation-rates in relation to erythema, arthritis, and pericarditis. At 1 the plasma clot was totally resistant to fibrinolysis; at 2 and 3 it was completely dissolved.

The cases were divided into two groups, those in which there had been a recent acute or subacute attack of infection or relapse of infection and in whom some clinical evidence of activity persisted at the time of examination, and those presenting no clinical evidence of active disease.

The clinical signs by which activity was recognised were: (*a*) fever; (*b*) joint pains with or without arthritic effusion; (*c*) elevation of the sleeping pulse-rate, as advocated by Schlesinger (1932); (*d*) appearance of new or an increase in previously recognised physical signs, such as pericardial friction; (*e*) loss of weight; (*f*) subcutaneous nodules. In some cases relapse was preceded by sore-throat.

It is generally agreed that the sedimentation-rate of the red blood-cells is an accurate clinical index of activity of infection in rheumatic children (Payne 1932, Bach and Gray Hill 1932, and Struthers and Bacal 1933), and it has been the experience of one of us (C. B. P.), based on over a thousand estimations of the sedimentation-rate in 163 cases of rheumatic carditis in children in all stages of the disease, that this estimation is probably the most reliable guide we possess to activity of rheumatic infection. It may rise before relapse is clinically manifest; without exception it remains high during its course and well into convalescence.

Our active cases are therefore divided into those in which the sedimentation-rate was over and those in which it was under 20.

Every case of serious active infection fell into the first group and the plasma clot of nearly half these cases was found to be completely resistant to fibrinolysis at some period during convalescence. Active cases with a sedimentation-rate under 20 were always those in whom relapse was relatively mild or who were studied at a late stage of relapse. In one only of these cases was the plasma clot completely resistant; in one-third of these cases there was considerable and abnormal delay in liquefaction. All the quiescent cases showed complete digestion of the clot usually well within the period found for normal bloods. Twenty-six children in the same age-period as the rheumatic children (5 to 15 years) were selected as controls. In none was there any manifestation or history of recent hæmolytic streptococcal infection. In all of them plasma clot was normally susceptible to fibrinolysis, and no instance of total resistance to fibrinolysis was found on examination ot the blood of 28 adults similarly selected as controls. Tillett, Edwards, and Garner tested the plasma clot of 30 "normal" adults and of 14 children and 16 adults suffering from various "non-streptococcal" diseases. Of their 60 controls fibrinolysis took place in four hours or less in 58, in one child it was delayed for 24 hours, but eventually complete, and one case, a child with a history of acute otitis media, which might well have been of hæmolytic streptococcal origin,

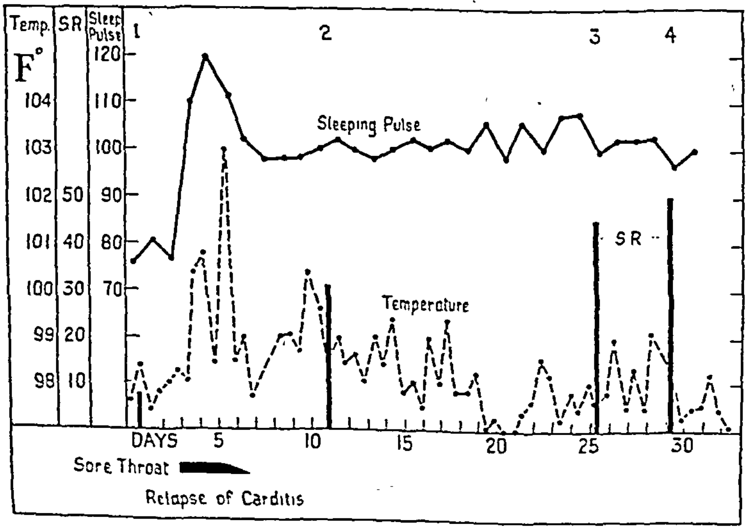

FIG. 3 (Case 1).—Temperature, pulse-rate during sleep, and erythrocyte sedimentation-rate, during a period of sore-throat followed by a relapse of carditis. At 1 the plasma clot was completely dissolved; at 2 and 3 it was completely resistant at 4 it was again completely dissolved.

was resistant. Taking these figures together, one case of total resistance to fibrinolysis has been found amongst 114 specimens of blood from individuals apparently not suffering from hæmolytic streptococcal infection (0·87 per cent.); whereas 12·5 per cent. of our 44 cases of children suffering from rheumatic carditis had totally resistant plasma clots, and in every resistant case there was clear evidence of active infection. Further it is very probable, judging from the results of Tillett, Edwards, and Garner in erysipelas, scarlet fever, and streptococcal tonsillitis, that we missed the period of "absolute resistance" in some of our severe cases, as they found this period may be delayed until the thirtieth day or even later in convalescence, and occasionally to last for as short a period as a week. This point could only be investigated by repeatedly bleeding each active case, a proceeding which is almost impracticable in the case of nervous children under the age of ten.

The following are the notes of cases selected from our series to show the relation between clinical signs and resistance or susceptibility of the plasma clot to fibrinolysis—in active cases with the sedimentation-rate over 20 (Cases 1 and 2); in an active case in which the rate was under 20 (Case 3); and in a quiescent case (Case 4).

CASE 1.—Girl, aged 13 (see Fig. 3). August, 1933: acute relapse of carditis with left-sided pleural effusion and many subcutaneous nodules. October, 1933: relapse with pericarditis. Gradual improvement with gain in weight and fall in sleeping pulse-rate to below alert pulse, and almost complete disappearance of nodules (a few doubtful remnants persisting on knees) by Feb. 19th, 1934, when the sedimentation-rate was 7, and on fibrinolysis test the clot was completely dissolved. Feb. 21st: fever and tonsillitis; streptococci present in throat swab. Feb. 26th: loss of 3 lb. in weight. March 1st: aortic diastolic murmur noted for first time; sedimentation-rate 30; fibrinolysis test, clot completely resistant. March 5th: pericarditis; hæmolytic streptococci present in throat swab. March 15th: pericarditis still present; sedimentation-rate 44; fibrinolysis test, clot completely resistant. March 20th: clinically improved; pericardial rub no longer heard; sedimentation-rate 49; fibrinolysis test, clot completely digested.

CASE 2.—Boy, aged 15 (see Fig. 4). Nov. 11th, 1933: pains in arms and legs and joints with swelling of the joints. Nov. 17th: admitted to hospital; no definitely abnormal cardiac physical signs; fleeting swelling and pain in all joints; marked erythema marginata over the whole body. Dec. 6th: sedimentation-rate 5. Dec. 15th: sedimentation-rate 12. Dec. 24th: much improved; erythema persists. Dec. 29th: rise of temperature; relapse of joint pains; apical systolic murmur; sedimentation-rate 34. Jan. 3rd, 1934: nodules on flexor tendons of hands; pains better. Jan. 4th: sedimentation-rate 23. Jan. 11th: sedimentation-rate 35. Jan. 19th: sedimentation-rate 9. Jan. 23rd: fresh rise of temperature with precordial pain and pericardial rub. Jan. 26th: sedimentation-rate 49. Jan. 31st: fresh rise of temperature with joint pains. Feb. 13th: nodules still present; no cardiac enlargement; no apical systolic murmur; no joint pains or rash; sedimentation-rate 27; fibrinolysis test, clot completely resistant. March 5th: all physical signs disappeared; sedimentation-rate 2; fibrinolysis test, clot completely dissolved. March 16th: steady improvement; sedimentation-rate 2; fibrinolysis test, clot completely dissolved.

CASE 3.—Male, aged 12½ years. Heart found bad at the age of three. Several relapses of rheumatism and carditis since then. August, 1933: acute relapse of carditis and arthritis; considerable cardiac enlargement, mitral stenosis, and aortic incompetence; steady improvement with gain in weight. Jan. 1st, 1934: slight pyrexia; no change in physical signs; sedimentation-rate 5. Jan. 15th: sedimentation-rate 4. Jan. 25th: pyrexia and rash; ? rheumatic erythema marginata; no definite change in cardiac physical signs; some loss of weight. Jan. 29th: sedimentation-rate 32. Feb. 19th: better again; sedimentation-rate 13; fibrinolysis test, clot partially resistant.

CASE 4.—Aged 8. Rheumatism and carditis, October, 1932, followed by relapse of rheumatism a year later. Steady improvement with gain in weight and decrease in abnormal cardiac physical signs. Feb. 19th, 1934: no cardiac enlargement and only soft apical systolic murmur; sedimentation-rate 9; fibrinolysis test, clot completely dissolved. March 5th: very well; sedimentation-rate 7; fibrinolysis test, clot completely dissolved.

Table II. summarises the results of fibrinolysis tests in rheumatic children :—

TABLE II

Total ..	9	12	23	26

Discussion

All the available methods of measuring streptococcal immunity indicate that it is short in duration and relatively slight in degree. The estimation of anti-fibrinolysin and anti-hæmolysin production shows the same irregular results as the estimation of anti-bacterial, antitoxic, and allergic antibodies. It appears likely, however, that the determination of the resistance to fibrinolysis, provided a powerfully lytic strain of coccus is used, can be carried out with less elaborate precautions than agglutination and precipitin tests, and, as resistance appears to follow the majority of hæmolytic streptococcal infections, its determination may prove more generally useful than an attempt to determine the degree of antitoxic immunity by skin tests, as many strains produce little or no toxin.

Resistance to fibrinolysis apparently due to anti-fibrinolysin production bears a close analogy to the production of antihæmolytic antibody. Todd (1932), Coburn and Pauli (1932), and, more recently, Myers and Keefer (1934) have shown that hæmolytic streptococcal infection is often followed by a considerable increase in the anti-hæmolysin titre of the blood, and that patients with active rheumatic infection show a similar rise as often as do patients with frank hæmolytic streptococcal infection.

The number of fibrinolysis tests on rheumatic children here recorded is too small to draw definite conclusions, but the relation between total and partial resistance and clinical activity is close enough to suggest that a short-lived immunity to hæmolytic streptococci follows each attack of infection.

As far as they go our results are in accord with the findings of Todd, of Myers and Keefer, and of Schlesinger and Signy, and furnish additional immunological evidence that hæmolytic streptococci play an important part in acute and subacute rheumatism, even if they furnish no proof of its streptococcal origin.

Conclusions

(1) Broth cultures of 11 out of 30 strains of hæmolytic streptococci were found to liquefy human

fibrin rapidly. (2) The majority of these lytic strains were isolated from cases of severe human infection, and with one exception their colonies on solid media were "rough" and they were virulent to mice. (3) Weakly fibrinolytic strains had glossy colonies and were much less virulent. (4) The liquefaction of human plasma clot by hæmolytic streptococci is not related to its fibrin content. (5) Total resistance to fibrinolysis appears to be a specific immunity response to infection by hæmolytic streptococci. (6) The plasma clot of children suffering from acute and subacute rheumatism was frequently found to show total resistance to fibrinolysis.

In the case of one of us (C. B. P.) this work was carried out during the tenure of a medical research fellowship granted by the Colston Research Society. We are grateful for this assistance.

THE TREATMENT OF PROFUSE BLEEDING FROM THE STOMACH AND DUODENUM

BY R. S. AITKEN, M.B. N.Z., D.Phil. Oxon.,
M.R.C.P. Lond.

FIRST ASSISTANT IN THE MEDICAL UNIT, THE LONDON HOSPITAL

THERE is no general agreement about the principles on which cases of profuse bleeding from the stomach and duodenum may best be treated. This is unfortunate, because severe cases, where the bleeding is grave enough to threaten life, often come under the care of hospital residents and practitioners whose individual experience of the emergency is not great. The main choice lies among three courses of action: purely medical treatment, medical treatment plus blood transfusion, and surgical treatment. The conservative teaching recommends medical treatment only, and in the absence of an extended experience of other methods the wise course is clearly to follow that teaching. It is usually coupled with the comforting assurance that very few cases so treated die. It is doubtful, however, whether the fatal cases are in fact few enough to offer much comfort, when it is remembered how common profuse bleeding is. Published figures vary from Hurst's 2½ per cent. mortality among cases admitted to Guy's Hospital on account of hæmatemesis or melæna and not previously operated on, to Chiesman's 25 per cent. mortality among cases admitted to St. Thomas's Hospital for gross hæmatemesis and melæna. Statistics on this subject are particularly difficult to appraise, because no exact limit can be set to the degree and recency of bleeding that justifies admission of a case to a series, and because statistics take scant account of the very variable circumstances and features of different cases. Nevertheless, it does seem clear that approximately 10 per cent., at least of the moderately severe cases, die. This is no negligible minority. Hæmatemesis and melæna are so common that fatalities represent a considerable number of lives, and it is no credit to modern medicine that these are still lost from a cause so clearly understood and—in theory—so easily remedied as hæmorrhage from the stomach or duodenum.

The best use of the three methods mentioned above (medical treatment, transfusion, surgical treatment) is clearly to be found only by experience, for none is infallible, and each has its dangers. Bare statistics are an unreliable substitute for experience. On the other hand few observers, if any, have had adequate experience of all three methods, and if they have none has published an appraisal of them that has won widespread assent. The problem can best be studied, then, by collating the experience of a number of observers using these methods. This I have attempted to do, using the records of the London Hospital, which are in most cases sufficiently full for the course and the severity of the cases to be fairly accurately judged. The records chosen were examined from the point of view of estimating the value of medical treatment, transfusion, and surgical treatment, in dealing with uncomplicated urgent bleeding of the stomach and duodenum.

CASE RECORDS

The records of 262 cases have been examined, belonging to the years 1929–33 inclusive. These comprise:—

(a) All cases admitted to hospital *on account of* recent hæmatemesis or melæna, with the exception of those in which the clinical diagnosis of cirrhosis of the liver was unequivocal. "Recent" means occurring within 14 days before admission; all cases were admitted because they bled, and would not have been admitted when they were, had they not bled.

(b) All cases manifesting hæmatemesis or melæna of significant amount while in hospital, following admission on other grounds, excluding, however, cases of post-operative bleeding. By "significant amount" is meant several ounces or more.

From these 262 cases 7 have been discarded, all of them fatal ones, on the ground that in 4 of them serious complicating disease was present in organs other than stomach or duodenum and largely contributed to death, and that in 3 cases of bleeding ulcer death occurred from perforation.

Of the remaining 255 cases, 27 died, directly or indirectly from hæmorrhage, giving a mortality figure for what it is worth of 11 per cent. Of the whole series of cases, many suffered relatively small loss of blood, were never in danger of their lives, and never caused anxiety to those in charge of them. They were treated medically, and for the purpose of this inquiry must be set on one side. The remainder are the grave cases, in whom the bleeding constituted a threat to life, and these have been retained. They comprise (a) the 27 fatal cases, (b) 15 cases in which bleeding had reduced the red cells to 2,000,000 or less, or the hæmoglobin (Dare) to 20 per cent. or less, (c) 21 cases in which blood counts were lacking, but in which a similar grave degree of blood loss was indicated by clinical condition, recurring hæmatemesis, or rising pulse-rate.

They are discussed in three groups according to their treatment.

CASES TREATED MEDICALLY

There were 31 cases, with 17 deaths. The medical treatment consisted fundamentally in complete rest in bed, morphia, and by mouth either nothing at all or minimal quantities of water or ice. Some patients also received adrenaline or calcium lactate by mouth, saline solution rectally, or hæmoplastin subcutaneously.

A. *Patients who recovered* (14).—Ages: 22 to 63, average 41. Source of bleeding: chronic ulcers were proved by radiography or subsequent operation in 7 cases, 4 gastric, 2 duodenal, and 1 jejunal; acute ulceration or erosion was diagnosed in the remainder. In 6 cases hæmatemesis recurred once or oftener during the first few days in hospital; the remainder probably ceased to bleed on admission or shortly after.

B. *Patients who died* (17).—Among these is included an infant of two days which bled to death from a duodenal erosion without evidence of sepsis. The following observations concern the other 16 cases. Ages: 23 to 74, average 51. Source of bleeding: ulcers with macroscopic perforation of arteries in their bases were found post mortem in 8 cases (6 gastric and 2 duodenal), and carcinoma of the stomach was found in 3; post-mortem examination was disallowed in the remaining 5, 2 of whom (women aged 23, 25) were thought to have acute gastric ulcers, while the remainder probably had chronic ulcers. One patient died four hours after admission to hospital, 2 about 24 hours after admission, the others after longer periods. In 6 at least there was clear evidence of recurrent bleeding in hospital. Most of them died directly of exsanguination. A few showed respiratory infections (bronchitis or broncho-pneumonia) developing after the initial bleeding, and one woman of 74 had thrombosed pelvic veins and pulmonary infarcts; these were contributory causes of death, but were themselves presumably secondary to the hæmorrhage. If the woman of 74 be excluded on account of her age, together with the 3 malignant cases, there remain 12 patients who died of gastric or duodenal hæmorrhage, under medical treatment; these constitute about one-third of the grave cases so treated, and they are deaths which should not be regarded complacently.

CASES TREATED MEDICALLY WITH THE ADDITION OF BLOOD TRANSFUSION

In this group there were 11 cases, with 3 deaths. The ages were from 15 to 64 (average 41). The sources of bleeding (judged usually from clinical evidence or subsequent X ray examination) were: chronic gastric ulcer in 3 cases, chronic duodenal ulcer in 4, chronic jejunal ulcer in 1, acute ulceration in 2, and carcinoma of the stomach in 1 (non-fatal).

The following are three examples of recovery following transfusion:—

CASE A.—Female, aged 64. History of hæmatemesis at the age of 23, but no subsequent dyspepsia. She vomited blood 10 times during the 4 days preceding admission, and was admitted extremely pale and collapsed, with an almost imperceptible pulse, rate 130. She was given morphia subcutaneously and ice to suck; 3 hours after admission she received a transfusion of 350 c.cm. citrated blood. The pulse-rate fell steadily to 80 in 24 hours, no further hæmatemesis occurred, a modified Lenhartz diet with alkalis was begun on the fourth day, and she made a good recovery. Subsequent X ray examination showed evidence of ulceration on the posterior wall of the stomach, and what appeared to be an old spontaneous gastro-jejunal fistula.

CASE B.—Male, aged 26, had suffered for years from attacks of abdominal pain after food. For 3 weeks before admission he had pain every day. On the day of admission he vomited half a pint of blood before being sent to hospital, and had 4 further hæmatemeses in hospital. He was pale with a pulse-rate varying between 86 and 116, red cells 2,000,000, hæmoglobin (Dare) 18 per cent. A transfusion of 360 c.cm. was given, and a modified Lenhartz diet with alkalis was begun. Hæmatemesis recurred on the day after admission and again on the fourth day, causing the pulse to rise from 102 to 134. A second transfusion was then given, after which recovery proceeded slowly but steadily, notwithstanding a further small hæmatemesis on the sixth day. Subsequent X ray examination showed an irregularity high on the lesser curve, interpreted as a healing ulcer.

CASE C.—Female, aged 58, had suffered from attacks of abdominal pain for 13 years and had once been operated on. For a week before admission she had been pale and felt giddy, and passed tarry stools. On admission her pulse-rate was 106–112, red cells 2,600,000, hæmoglobin 38 per cent. She was treated on the usual medical lines, but on the seventh day became extremely weak and ill, with temperature 100°, pulse 130. Melæna continued, her condition showed little change for the next 5 days, and the pulse-rate remained about 120–124. A large transfusion (900 c.cm.) was then given. Next day the pulse was down to 100–108, the melæna soon ceased, and recovery proceeded. Subsequent X ray examination showed a gastro-jejunostomy and duodenal deformity. The immediate result of this large transfusion was to raise the blood pressure from 115/65 to 125/75 mm. Hg; an hour later it had fallen again to 110/70 mm. Hg.

The details of the three cases in which death followed transfusion are these:—

CASE D.—Male, aged 51, had had periodic dyspepsia for 4 years. An attack, with epigastric pain after food, began 2 weeks before admission, melæna occurred 2 days before admission, and on the day of admission he vomited blood and fainted. He was admitted pale and somewhat collapsed, with a pulse-rate of 100, red cells 3,000,000, and hæmoglobin 30. He was given morphia, and nothing at all by mouth. Hæmatemesis (37 oz. in all) occurred 3 times in the first 24 hours, but not subsequently. The temperature rose in the first 3 days gradually to 103°, and the pulse record fluctuated, sometimes rising to 150. Subcutaneous saline was given. He then became mentally deranged and restless. On the fourth day he received a transfusion of 500 c.cm. of blood, but without showing any improvement. Morphia failed to control his semi-delirious condition, and on the sixth day, with pulse rising to 160, temperature 102·5°, and no increase in respiration-rate, he died. Post-mortem examination was not allowed, but the cause of death was no doubt continued bleeding. The anæmia precipitated the mental condition, and the resulting restlessness probably helped to maintain the bleeding.

CASE E.—Male, aged 51, was admitted to hospital for investigation, complaining of upper abdominal pain and vomiting for 3 weeks. While in hospital he suddenly became weak and pale; next day he vomited blood, his pulse rose to 122, and blood examination showed 1,300,000 red cells and 20 per cent. hæmoglobin. There was little change for 2 days, and he was then given a transfusion of 350 c.cm. The following day he developed œdema of the lungs, his temperature rose to 106°, and he died. Post mortem a chronic duodenal ulcer was found with an eroded artery in its base; the lungs were œdematous. Death appears to have been caused by acute heart failure rather than by anæmia; this may have been an abnormal reaction to the transfusion.

CASE F.—Male, aged 30, had undergone a gastro-jejunostomy for duodenal ulcer 7 years previously, and had had pain and melæna on two subsequent occasions. He vomited blood on two successive days, and was then admitted pale and collapsed, with a pulse-rate of 110. He was treated medically. A rise in pulse-rate to 150 indicated further bleeding on the day after admission, but it fell again to 80–90, and on the fifth day he appeared to be doing well (hæmoglobin 39 per cent.). On the sixth day he collapsed and his pulse rose steadily to 125. His condition was then extremely grave, and the physician in charge described him as moribund. A transfusion of 600 c.cm. was given. The steady rise in pulse-rate continued, and he died 6 hours later. Post mortem a chronic jejunal ulcer was found with an eroded artery in its base.

CASES TREATED SURGICALLY

There were 21 cases, with 7 deaths. The ages ranged from 24 to 62 (average 45). In all of them operation was undertaken with the object of stopping bleeding. The details of these cases are shown in the accompanying Table. The patients, many of whom had been referred by physicians, were all gravely ill from loss of blood, with the exception of the first two, in whom the bleeding was apparently somewhat less severe and transfusion was not given.

GROUP III.—CASES TREATED SURGICALLY

No.	Sex and age.	Operative procedure.	Result.
1	F. 59	G.U. embedded. Gast.-jej.	Recovery.
2	M. 45	G.U. found. Gast.-jej.	,,

13	M. 53	No ulcer found. ? Cirrhosis of liver. Trans.	,,
14	M. 51	No ulcer found. Trans.	,,
15	M. 41	G.U. excised. Trans.	Death 2 days later. No P.M.
16	M. 43	G.U. excised. Trans.	Death 6 days later from [illegible]
17	M. 57	G.U. embedded. Gast.-jej. Trans.	[illegible] later. [illegible] In- [illegible] P.M.
18	M. 47	Gastrotomy. G.U. not found. Trans.	[illegible] from hæmorrhage and broncho-pneumonia. P.M.: eroded arteries in a high G.U.
19	M. 24	D.U. embedded. Gast.-jej. Trans.	Collapse and death immediately after operation.
20	M. 62	Anterior D.U. embedded. Gast.-jej. Trans.	Death 2 days later. P.M.: eroded arteries in base of a *posterior* D.U.
21	M. 32	D.U. embedded. Gast.-jej. Trans.	Death from hæmorrhage 5 days later, after 2 further transfusions. P.M.: eroded artery in base of D.U.

G.U. = gastric ulcer; D.U. = duodenal ulcer; P.M. = post-mortem examination: Gast.-jej. = gastro-jejunostomy; Trans. = transfusion.

DISCUSSION

For the reasons mentioned in the introduction no valid statistical conclusions can be drawn from these case- and mortality-records. They do, however, broaden the outlook of anyone who has had some experience of similar cases. The attempted separation into less severe cases and grave cases throws into relief the fact that a large proportion of the latter (27 out of 63) died. Though the line of separation is not a hard-and-fast one, yet it is nearly always possible to say clinically whether a given case is grave or not. It is therefore well to know that 3 out of every 7 grave cases are likely to be fatal. This is obscured by the common method of expressing the mortality-rate as a percentage of all cases. Whether the figure, 3 out of 7, obtained from this series holds exactly for other series does not affect the argument. Since this series has a general mortality-rate of 11 per cent., it is probably a fairly typical series and justifies the inference that something between one-fourth and one-half of grave cases of gastric and duodenal bleeding end fatally.

There is no means of predicting with any accuracy which grave cases will die. Under purely medical treatment some go apparently very near to death and then recover; others die unexpectedly, or develop unforeseen respiratory or mental complications which turn the balance against them. Patients with a dyspeptic history suggesting chronic ulcer, and patients who have not had dyspepsia, as well as malignant cases, are found both among the recoveries and among the deaths. Any attempt therefore at further subdivision of grave cases with a view to individual prognosis seems useless.

It remains simply to review methods of treatment and to attempt to assess them empirically. In this series the mortality was heaviest among the cases treated medically; this remains true when the malignant cases and those at the extremes of age are excluded, and it definitely lays the conservative teaching of medical treatment in *all* circumstances open to criticism. The results of a surgical attempt to deal directly with the bleeding point, in a group of cases of similar severity, appear slightly better; they show at least that, in expert hands, operation on these exsanguinated patients is not necessarily a sentence of death. The middle group of cases, treated medically with the addition of one or more blood transfusions, deserves closer consideration. It showed—for what it may be worth—a lower mortality than the other two groups; and of its three fatal cases, one was already mentally deranged and another was moribund when the transfusion was given. Eight cases, however, were transfused while still bleeding, or shortly after the cessation of bleeding, and they recovered. This sets the evidence of experience against the theoretical view that transfusion, by raising the blood pressure, will merely increase the loss of blood from the bleeding vessel or vessels, and in that respect is in line with the experience of those who treated secondary hæmorrhage in war wounds by transfusion.

From a review of the whole series of cases studied in this paper the following recommendations emerge for the management of gastric and duodenal bleeding (hæmatemesis and gross melæna):—

1. A distinction should be made, clinically, between grave cases and less severe ones. Recurrent bleeding is often but not always grave. Cases in which the red cells fall below 2,000,000 or the hæmoglobin below 40 per cent. (on a scale on which the normal is 100 per cent.) will usually be grave. The distinction is to be made, however, on consideration of the whole clinical picture.

2. The less severe cases should be treated on the accepted medical lines.

3. The grave cases should be treated medically, in bed, with sufficient morphia to ensure complete rest; and a transfusion of about 500 c.cm. of blood should be given, without moving the patient from his bed, after careful cross-grouping.

4. If further bleeding is indicated by subsequent hæmatemesis or rising pulse-rate, the transfusion should be repeated once or twice within the next 24 to 48 hours, or when necessary.

5. If bleeding still continues and the patient's condition deteriorates, operation should be promptly undertaken, along with a further transfusion. The operation should probably be restricted to the minimum procedure necessary to find and secure the bleeding point.

These recommendations are substantially the same as those given by Hurst in his book on "Gastric and

Duodenal Ulcer" in 1929. Bastedo in America and Tzanck in France agree in advocating transfusion in addition to medical treatment for grave cases, and in reserving surgery for those few cases in which the bleeding continues in spite of repeated transfusion. This course does not appear to have been widely practised in this country; it was not considered by any of the four opening speakers in a recent discussion on the treatment of hæmatemesis in the sections of medicine and surgery of the Royal Society of Medicine. This paper is a plea for its more extended trial.

I am indebted to the physicians and surgeons of the London Hospital for their permission to use the records of their cases.

CARCINOMA OF THE RECTUM *

BY DUNCAN C. L. FITZWILLIAMS, C.M.G.,
M.D. Edin., F.R.C.S. Eng.

SENIOR SURGEON TO ST. MARY'S HOSPITAL, PADDINGTON, AND MOUNT VERNON HOSPITAL FOR CANCER RESEARCH

CARCINOMA of the rectum forms an important part of the carcinomata which infest the intestinal tract. Of the different portions of that tract cancer of the oral cavity is one-third, that part of the tract extending from the œsophagus to the rectum produces less than a third, and the small remaining portion of the bowel makes up for more than a third.

Men and women are affected in equal numbers. The age-incidence is curious as it attacks people from puberty to old age, but there is this difference—in cancer of the rectum there are more people affected in the teens than in cancer of any other part of the body. There are 11 per cent. under 30, and 4 per cent. under 20 years of age. Between 50 and 60 are the commonest ages.

Pathologically it is very simple; it is an adenocarcinoma, starting in the [illegible]ical cells of Leiberkuhun's glands. The c[illegible]tion to this is a squamous-celled carcinoma [illegible] starts at the anal margin and is analogous to carcinoma of the lip. From here it may spread to the rectum, but I am going to disregard this form. The start of cancer must presumably be a small ulcer or a warty papilloma; in many cases we see a well-established cancer and close by a wart still in the innocent stage. High up in the rectosigmoidal region it tends to spread round the bowel so as to form what is called a string stricture. Lower down, in the ampulla of the rectum, it usually starts in the posterior wall, while near the anal canal it tends to start in the anterior wall.

There are three varieties or forms of growth, though microscopically they are all the same. They are:—

1. The papilloma or cauliflower-like mass where growth is pronounced and ulceration at a minimum. Here it forms a prominent mass in the bowel, spreads superficially and does not contract the walls—in fact, it may balloon the bowel considerably. I have seen a mass in the rectum considerably larger than a shut fist. It only affects the bowel wall superficially for a considerable time, and is therefore the least malignant form; though it may give rise to a considerable amount of obstruction by its size alone, the glands are often only enlarged by sepsis.

2. The adenoid or common form is the opposite, as here growth is at its minimum and destruction at its maximum. A shallow ulcerated area with hard edges is the result. This spreads round the bowel, rapidly infiltrating the muscular coat, and is therefore highly malignant affecting both the glands and the liver. It stenoses and obstructs the gut rapidly.

3. The colloid form is rare and is really a degeneration of the other two types.

METHOD OF SPREAD

Growths of the rectum tend to spread transversely round the bowel across the lumen, superficially in the mucous membrane; the penetration of the muscular coat is slow. Once it has penetrated the muscular coat the matter is more serious as it gains the perirectal space. This is a considerable and roomy space filled with fat which allows the bowel to expand and fill with its contents and then to collapse as its contents are voided; a certain pump-like action is therefore present which tends to spread carcinomatous cells. Hence the fascia propria or lining membrane of the pelvis becomes infected and, lastly, the neighbouring organs—namely, the vagina, uterus, prostate, bladder, and the sacrum. The veins of the bowel are important, as it is by this means that the secondary growths reach the liver. Our old teaching was that sarcoma was spread by the blood stream and carcinoma by the lymph stream. We now know that carcinoma spreads by both routes very easily, the fact of the matter being that the delicate cells of carcinoma are destroyed, being filtered out of the blood stream by the lungs, and many years ago observations were made of the difficulty these cells had in growing in the lungs when secondarily deposited there. Carcinoma cells, however, grow and flourish very readily in the liver when carried there, hence it is that the early secondary deposits are often found in the liver even before any glands can be felt affected. This very important point in treatment and prognosis will be referred to later.

The lymphatics in the bowel wall drain into the subperitoneal lymphatics where the peritoneum is present, and in other situations into the lymphatics of the perirectal fat directly. From here the lymph drains into the lymphatics which lie along the superior hæmorrhoidal vessels—the rectal glands of Gerota. From here it passes mainly up the mesosigmoid, along the inferior mesenteric vessels to the bifurcation of the left common iliac vessels, and so to the aortic glands.

Some lymph may pass downwards to the inferior hæmorrhoidal vessels, through Alcock's canal to the internal iliac glands whence it joins those mentioned above. Or the lymph may pass out with the levator ani muscles again to the internal iliac glands.

SYMPTOMS

Unfortunately cancer of the rectum in its early stages is as silent a disease here as elsewhere, and may quite well exist from six to twelve months without giving rise to any noteworthy symptoms. The earliest symptom, if indeed it can be called such, is for the bowels of a person of regular habits to become slightly constipated. This is due to inertia of the sigmoid and some interference with the normal peristaltic action. This, however, is hardly likely to create much alarm or send the person to seek medical advice. This constipation may alternate with mild diarrhœa, but this again is not

---

* A clinical lecture given at St. Mary's Hospital Post-Graduate Course.

alarming if the person is trying to regulate his bowels with unaccustomed purgatives.

The symptom which should attract the attention of the medical man and at once rivet his attention is the history of what the patient terms a slight diarrhœa which lasts three weeks or a month. Little is passed at a time, there is no straining but perhaps some mucus. The bowels act after meals or after hot drinks, not more than three or at the most four times a day. Later a little blood may be noted.

In the adenoid form stenosis occurs and the diarrhœa is equally well marked as only fluids can pass the stricture, but here there is little mucus and seldom any blood. If the growth is low down in the bowel there may be discomfort, and the patient thinks he has piles as there is a feeling of incomplete relief after motions. In these lowly situated growths the history is so often the same that I will recount a case.

The person, as I have already stated, thinks he has piles; he talks to his friends, one of them is sure to have had piles, and confirms his views. Often the friend tells him what to do and prescribes the remedies that were beneficial in his own case. As this does little good he eventually meets his doctor and says casually, "Oh, Dr. A., I have been suffering lately from piles—nothing much you know, but they are uncomfortable." It is in the next few minutes that his fate is decided. If Dr. A. is a careful man he says, "Well, come and see me to-morrow and I will examine you," and the next day he puts his finger in the rectum, the growth will be felt, the diagnosis made, and he may be saved. But if Dr. A. is haphazard and believes what his patient says and does not examine him, the golden opportunity is lost and the patient is surely doomed. Remember that you must always put your finger in the patient's rectum the first time you see him about his piles, for if you do not you will never do it later; you will think you have done so and the opportunity for early diagnosis is lost. Later, when the treatment you have advised does not act, you will change it or tell him to persevere; so time goes on and the condition slowly gets worse, until he is thoroughly fed up with it and goes on advice—probably of a friend—to see Dr. B. Now, curiously enough, however careless you may be of your own patients you are never careless in the case of patients coming from the opposition, and Dr. B. puts his finger in the rectum and diagnosis is made. The wife or the friends are told the truth, the patient suspects—he knows well enough that Dr. A. never examined him—and I leave it to your imagination as to what is said in the provincial town about Dr. A. The other and more happy variation of the story is for Dr. A. at last to examine the rectum after a delay of perhaps six months. In my ward at the moment are patients who can give both these histories.

As time goes on, in any form of the disease ulceration may occur or become more marked and with this pain will appear, a dull aching in the region, mucus and blood will become more marked, and pus will be seen. In the later stages more depressing symptoms appear, the rectal wall becomes penetrated, and there is spread to the adjacent organs. Pain is noted down the back of the thighs from involvement of the sacral nerves. Colic and distension accompany constipation and diarrhœa. The chronic obstruction may at any time become an acute affair. Loss of weight is now a feature of the disease. The prostate may be involved, upsetting the function of the bladder. Fistulæ may form between the rectum, bladder, or vagina. Lastly, œdema of the legs appears, jaundice ensues, and there is general carcinomatosis and death.

DIAGNOSIS

When the various conditions which exist in the rectum are considered there appears very little which can simulate a really established cancer. When, however, we look for so-called classical symptoms and find them, we at the same time find a doomed case. This being so it only remains to mention the conditions which might be mistaken for the early stages.

Intussusception of a simple papillomatous growth may take place, but the tumour can be felt floating in the bowel. The lumen is in the centre of the tumour, and the finger can be passed round it. There is often a lump felt in the left iliac fossa and there may be signs of chronic obstruction. A villous papilloma is sometimes felt as a soft growth which can be moved about with the finger; it secretes a watery fluid which may cause frequent evacuations.

An adenoma may be single or multiple; it is firmer than the villous tumour, lobulated but devoid of induration. It may be pedunculated or sessile. It is as well to bear in mind that these papillomata or warts are liable to become carcinomatous here as elsewhere. When multiple, it is curious to find that more than one may be taking on malignant characteristics. Multiple cancers of the rectum, which are not uncommon, start in these warts if they are not implantation cancers from a growth high up. I show you here a specimen where there are four separate carcinomatous ulcers and some innocent warts.

An adenomyoma starting in the cervix or vagina may form a prominence into the rectum. Such cases naturally are rare and not easily recognised. They are always defined and very hard, and the mucous membrane moves freely over them. Some cases of diverticulitis may simulate early carcinoma, but X ray examination will distinguish them at once.

Diagnosis is made from the history of the case, the examination of the abdomen, the examination of the stools for blood and mucus, and the digital examination of the rectum. Added to these there is the special examination of the rectum with the sigmoidoscope; often an anæsthetic may be required if this is to be satisfactory. Lastly, the barium enema combined with actually seeing the opaque fluid run into the bowel under the X rays, when a better idea is obtained than from the photograph, of the extent of the growth and the mobility of the bowel which can be seen to move or remain fixed when manipulated by the hand on the abdominal wall.

In performing the digital examination in the female it is better to make her lie upon her right side, but in the male there is nothing to compare with the knee-elbow position. The mobility of the growth should be made out and the extent, if possible, of the constriction—if the finger can be inserted through it—the depth of the ulceration, and the condition of the edges. It may quite well be that a growth which started well out of reach of the finger may descend, partly by growth and partly by intussusception to within easy reach of the finger, so that an examination may previously have been made by the doctor and nothing discovered, then at a later date the consultant may easily feel it.

TREATMENT

Cancer of the rectum is only partly accessible, therefore the diagnosis is seldom made at an early date and inoperable cases are common, but how common they are is perhaps not realised. It is safe to say that 75 per cent. of the cases are inoperable when diagnosed. Even in private practice 50 per cent. are inoperable. In the figures recently published for one of the London hospitals, out of 123 cases only 29 were operated on, and of these 9 died from the operation.

The chief general points which militate against operation are the age of the patient, for the older they are the worse the result. There are few cases over the age of 65 who are fit to undergo the radical operation. Stout people bear the operation badly. Any general condition such as a bad heart, arteriosclerosis, high blood pressure, albuminuria, diabetes absolutely contra-indicates radical measures. Lastly, we have the findings at the colostomy operation which so often decide one against further surgical procedure.

Of the type of operation the old form of Kraske is gone. We now have the abdomino-perineal operation or one of its modifications such as Coffey's operation, or the perineal operation which is a modification of Kraske's. Whatever operation is adopted a preliminary colostomy should be insisted upon. The health of the patient improves immensely after a colostomy, the bowel is washed free, and the septic absorption is diminished, colic and pains cease, and the patient is at ease. Therefore it is the best preliminary for the next operation if one is to follow. The chief advantage, however, is the information gained in performing the operation, for we do far more than establish a colostomy. What we do is of paramount importance both to us and to the patient, and too often the important parts of this procedure are overlooked, and only a colostomy is performed. The incision must be large enough to enable the hand and arm to enter the abdominal cavity. The hand passes to the pelvis and the extent, mobility of the growth, and spread of the disease is determined. The rectal and abdominal glands are sought for and felt, the peritoneum round about is searched for suspicious plaques, and, lastly, the dome and under-surface of both lobes of the liver are investigated. If there is already a secondary growth in the liver, further operation is out of the question. This is the part of the operation which too often is overlooked, it is not mentioned, as far as I know, in any book, but its importance must be clear to you all, for what can be the use of submitting a patient to a risky operation like the radical removal of the growth when his death warrant is already signed and sealed in his liver?

Lastly, there is the advantage that the rapidity of growth diminishes after colostomy is performed. The rapidity of tumour growth depends upon its vascularity, the irritation of the fæces passing over the ulcerated surface or squeezing through the stricture must increase this vascularity. As a result of colostomy the bowel remains empty, disused, and relatively anæmic; growth in consequence is proportionately slower.

Surgeons sometimes have cases sent to them for operation upon whom a colostomy has already been done. At this operation no attempt perhaps has been made to ascertain the operability or the presence of secondary growths, and in any case it may be impossible to communicate the knowledge to the second surgeon. If we operate we do so in the dark without the knowledge so essential to success, and we run the risk of discovering that the case is inoperable half-way through the operation. If the colostomy has been done to relieve an acute obstruction it may have been impossible to find out these points, owing to distension or the critical state of the patient. My rule in such cases is to open the peritoneal cavity and ascertain the state of affairs; otherwise harm may be done in stirring up an inoperable case or performing a useless operation upon a person who already has secondary masses in the liver.

Should the case be unsuitable for operation th patient needs to be taught the right way to li after colostomy is established. The bowels act b habit, and habit can be taught to the sigmoid colo just as it can to the bowel below it. If the patie wants comfort he must take trouble, and if he wi take trouble with his colostomy opening it is th rarest thing for him to be let down. Eac finds out what suits him best and the more troub he takes with the details the greater is his comfor I have a patient at the present moment who attende Ascot last year and also the garden party at Bucking ham Palace, and I do not think any of her friend even suspect her condition. The patient with colostomy will tell you he has no inconvenienc except when washing himself. A tube is passed an the large bowel washed empty and the fluid draw off; a stomach-tube with lateral holes should b used. With practice it can be passed round to th cæcum; it is important to draw off all the fluid s that there will be no leakage later. For the wash-ou there is nothing so useful as the rubber kidney tray made by Down Bros. Ltd. at my suggestion, whic takes the shape of the body. A piece of gauze smeare with vaseline is applied over the colostomy opening and an abdominal belt with a flat piece of thic rubber is worn over it. This should prevent al leakage until the next wash-out is given. Colostom belts with cups or receptacles should be avoided.

A diet is chosen which does not give rise to wind but flatus even only rarely escapes and is absorbe again. The lower portion of the bowel should b washed out with a mild antiseptic, such as wea sanitas, as required; some do it twice a week depending on how much secretion there is. Needless to say, it should be freed from fæces as soon as possible.

Now can anything be done to check the growth of the tumour? I think it can. A month to six weeks after the patient goes home he reports to me again. I pass down into the lower portion of the bowel through the colostomy opening a specially made narrow sigmoidoscope tube and examine the growth and insert a well-protected tube of radium, containing about 30 mg. of radium, into the stricture. This is left in place for four to five hours. Next day the tube is placed in the stricture from the anal orifice for the same length of time. The patient is then given one free day and the same thing is repeated. In this way a dose of about 500 mg. hours of radiation is given directly to the growth. This is repeated at intervals of about a month for three times, and at the end of that time the growth in many cases has almost disappeared, or at all events is sterilised and either does not grow at all or grows very slowly. I have several cases in which this has been carried out, and now no growth is perceptible. This, of course, has no effect upon secondary growths in the liver or intestines and holds out no hope of cure, but it prevents the spread to the neighbouring organs and the formation of fistulæ which render the last weeks of life so trying to these patients.

The cause of death in these cases is from secondary masses in the liver and elsewhere; this as a rule comes rapidly in the end, so that the patient suffers little.

AYRSHIRE HOSPITAL SERVICES.—The Ayrshire county council has adopted a scheme for the centralisation of the hospital services of the county under which a central hospital will be built at Kilwinning at an estimated cost of £210,000.

THROMBOPENIC HÆMORRHAGIC PURPURA

DUE TO IDIOSYNCRASY TOWARDS THE HYPNOTIC SEDORMID

ALLERGOTOXIC EFFECT

BY F. E. LOEWY, M.D. Vienna, M.R.C.P. Lond.

"Werlhof's disease"—the severest form of thrombopenic hæmorrhagic purpura—presents a well-defined clinical picture: a hæmorrhagic diathesis characterised by markedly prolonged bleeding time and tendency to petechial hæmorrhage. Slight injury to skin or mucous membranes by knocking, pricking, or pinching causes extravasations of blood and, after compression of the arm for about five minutes by a tourniquet (sphygmomanometer-cuff), numerous petechiæ appear in the area of passive congestion. The essential feature is the practical absence or severe reduction of blood-platelets.

This thrombopenic hæmorrhagic diathesis occurs regularly when the bone-marrow with its megacaryocytes has been extensively damaged by proliferating lymphadenoid (leukæmia) or neoplastic tissue, by excessive irradiation (radium, X rays), or by prolonged influence of certain poisons (benzol). Not infrequently the cause remains unknown—"essential thrombopenia." The spleen has been blamed in these cases, but the beneficial effect of splenectomy proves nothing, as no characteristic abnormality has been found in the excised organ and splenectomy regularly causes a rapid and sustained increase of platelets in healthy persons.

I have been able to prove that a typical case of Werlhof's disease and two milder cases of thrombopenic purpura were due to prolonged administration of the new hypnotic Sedormid (allylisopropyl-acetylurea) to hypersensitive patients. In the first case, after recovery, thrombopenic purpura was produced at will by giving ½–1 tablet of the drug (tablets of grs. 4 each). The elucidation of these cases was by no means simple, as sedormid has up to now been considered perfectly harmless and my patients had taken the drug repeatedly for some time without apparent ill-results.

THE CASES

CASE 1.—The first patient was a gentleman of 61 years, very highly strung and neurasthenic but never seriously ill. For the last six to ten years he had complained of general lassitude, had suffered frequently from indigestion with flatulence (irritable colon), and occasionally from insomnia. His blood pressure was low (118/85). The liver was slightly enlarged and hard, but not tender; the spleen was never palpable. At an alpine spa he was suddenly taken ill on Dec. 31st, 1930, with vomiting, flatulence, and slight rise of temperature. The diagnosis was at first coronary thrombosis, later influenza. Recovery was very slow, and delayed by general weakness, insomnia, constipation, and slight rise of temperature on and off for several months. He felt better during the summer and visited several spas. In September again he suffered from general weakness and had pain in both arms. A few pale purpuric spots were noted on the trunk on Sept. 10th. A week later marked purpura appeared on the right arm, which had been massaged. The extraction of a tooth was followed by severe hæmorrhage and rapid deterioration of the general condition. On Sept. 23rd there was purpura on both legs with large bruises over the right thigh; on Sept. 28th melæna; and on Sept. 30th hæmaturia.

On Oct. 5th I found the patient seriously ill. The whole body was covered with petechiæ and bruises; he passed tarry fæces and urine thick with blood. Bruises were easily produced anywhere by slight tapping. Bleeding time was prolonged over many hours. The blood count (Dr. H. Letheby Tidy) showed: hæmoglobin, 58 per cent.; red cells, 2,700,000; colour-index, 1; white cells, 9600 (polymorphonuclears 74 per cent., small lymphocytes 15 per cent., large mononuclears 3 per cent., eosinophils 4 per cent., myelocytes 4 per cent.); platelets, 22,000. In the evening hardly any platelets were seen in one smear. The condition seemed extremely dangerous and splenectomy was considered. A transfusion of 600 c.cm. of citrated blood was given, with immediate marked improvement of the bleeding tendency. He had a severe rigor. On Oct. 6th the tourniquet test was negative, and there were no more new spots. On Oct. 7th his hæmoglobin was 52 per cent.; red cells, 2,350,000; white cells, 6400; platelets, 120,000. On Oct. 8th his urine was clear, the fæces lightly coloured, and the platelets over 120,000; the tourniquet test was negative. On Oct. 9th the platelet count suddenly dropped again to 55,000; bleeding time was prolonged, and the tourniquet test positive but there was no spontaneous purpura. Hæmoglobin was 54 per cent.; red cells, 2,650,000; white cells only 3600 (polymorphonuclears 86 per cent., small lymphocytes 8 per cent., large mononuclears 3 per cent., and eosinophils 3 per cent.). The slight thrombopenia continued for the next two days without marked change in the general condition.

Lord Dawson, who had seen the patient in consultation, had suspected hypnotics as the cause of the illness but the patient had firmly resisted any attempt at withdrawal. After the transfusion he received grs. 7½ of Medinal nightly. On recovering strength he became more restless and insisted on receiving, in addition to the medinal, his favourite hypnotic sedormid, which he had been taking frequently in doses of 1–2 tablets since December, 1930, and especially regularly for several weeks preceding the transfusion. Two tablets of sedormid had been given during the night on Oct. 8th and 9th, and one more tablet on Oct. 10th. The recurrence of thrombopenia thus coincided with the resumption of sedormid. After Oct. 10th I allowed only bromides in addition to the usual medinal. From Oct. 12th onwards the platelet count rose again rapidly. On Oct. 16th the hæmoglobin was 66 per cent.; the red cells, 3,500,000; white cells, 9600; platelets, 360,000. On Oct. 23rd I again gave one tablet of sedormid to test the effect. Promptly the next morning purpuric spots appeared on both legs; the bleeding time was slightly prolonged and the tourniquet test positive, and there was slight hæmaturia. Only a few stray platelets were visible in one smear. The next day no further spots appeared, the tourniquet test was negative, and the platelet count rose rapidly and was normal again within a week.

I decided to make a final test on Nov. 4th. The platelets numbered then 502,000; red cells, 4,410,000; hæmoglobin, 87 per cent.; colour-index, 1; white cells, 12,600 (polymorphonuclears 43·5 per cent., lymphocytes 21·7 per cent., large mononuclears 7 per cent., eosinophils 27·8 per cent.). I gave half a sedormid tablet in the evening. After a good night numerous purpuric spots appeared next morning on the trunk, and especially on the right side, on which the patient had been lying. Bleeding time was prolonged over ten minutes, the tourniquet test was positive, and the temperature was normal. The platelets numbered 17,600. A blood smear showed slight leucocytosis (polymorphonuclears 46·7 per cent., lymphocytes 14 per cent., large mononuclears 9·3 per cent., eosinophils 29·3 per cent., basophils 0·7 per cent.). On Nov. 6th the platelets numbered 25,600; the tourniquet test was slightly positive. On Nov. 7th the platelets were 48,000 and the tourniquet test was negative. No more spots appeared, and on Nov. 19th the platelets numbered again 347,000. The case against sedormid was proved.

The patient is still under regular observation and has remained free from any signs of thrombopenia or hæmorrhagic diathesis. The platelets are always plentiful; there is frequently marked eosinophilia, and occasionally pruritus and complaints due to an "irritable colon." Skin tests with sedormid and the Prausnitz-Küstner test were negative.

Through the kindness of Dr. W. W. MacNaught I saw on June 1st, 1933, a second, less severe but unequivocal case of thrombopenic purpura caused by sedormid.

CASE 2.—Mrs. A, a lady of 60, had taken sedormid with good effect in doses of ½–2 tablets nightly for several weeks in the spring of 1932, after an abdominal operation. Recovery was delayed by pulmonary infarcts. For the last five and a half weeks she had again taken 1–2 tablets nightly. About one week after resuming the drug in 1933 she noticed purpuric spots, later also large bruises on different parts. Fresh crops of petechiæ appeared every few days, in spite of treatment with calcium. She had severe bruising at the site of an intramuscular injection of horse serum, and retinal hæmorrhages. The patient complained about pains in various joints and headache, but was not feeling severely ill. She was very highly strung and had been suffering for years from "nervous indigestion." I found the bleeding time markedly prolonged (over eight minutes) and the tourniquet test positive. The platelets numbered 28,000; the hæmoglobin was 78 per cent.; the red cells, 4,000,000; the colour-index, 0·9; the white cells, 6800 (polymorphonuclears 45·9 per cent., lymphocytes 40·6 per cent., large mononuclears 4·1 per cent., and eosinophils 9·4 per cent.).

Sedormid was stopped and no more petechiæ appeared. A week later the bleeding time was normal again and a blood smear showed platelets in approximately normal number and in big clusters.

CASE 3.—I was called on Dec. 22nd, 1933, to see the third patient, a married woman aged 51, who was very worried about bleeding from the gums. This had started two days before, a few hours after a sedormid tablet had been taken. There were also numerous purpuric spots on the trunk and legs, but at the time of examination the bleeding tendency was already improved. The bleeding time was normal; the tourniquet test negative; the hæmoglobin 95 per cent. The platelets numbered only 36,000 per c.mm. The patient, who was very nervy, had taken sedormid in doses of ½ to 1 tablet repeatedly during the last year and had experienced during that time several attacks of purpura, and once a small retinal hæmorrhage. Sedormid was stopped and no further hæmorrhages occurred.

PATHOGENESIS OF SEDORMID PURPURA

Sedormid is an ureid (allylisopropyl-acetyl-urea) similar in constitution and action to adalin (diaethyl-brom-acetyl-urea), and has been in use for several years as a sedative and mild hypnotic, apparently without any ill-effects. It was stated [1] in February, 1933, that no allergic disturbances had been observed after sedormid. A recent publication on thrombopenic purpura after iodine [2] reports without details the case of a woman who developed thrombopenic purpura after taking minute doses of iodine for several weeks. She recovered, but later had two relapses, each time the day after taking sedormid. She is said to have had no sedormid before (?).

The text-books contain no reference to thrombopenic purpura after hypnotics. After prolonged use of adalin,[3] itching patches and "purpura Majochi" have been seen in a few cases, but no thrombopenia. After abasin [4] (acetyl-adalin) a man of 58 years developed not only purpura Majochi and polycythæmia, but later also a mild thrombopenia. Nirvanol is a hypnotic (similar to phenobarbital) which usually produces a "toxic reaction" with rash, fever, and eosinophilia if given in small doses daily for one to three weeks. This reaction has been used in the treatment of chorea but has proved dangerous in certain cases, and in the case of a 17-year-old girl was accompanied by severe thrombopenic purpura.[5] It is interesting that the "drug rashes" caused by ureids with an open chain of carbon atoms (adalin, abasin, and now sedormid) develop insidiously without rise of temperature, while barbiturates with a closed ring of carbon atoms (medinal, luminal, nirvanol) are apt to cause acute rashes with marked general disturbance.[3]

ALLERGOTOXIC EFFECT

In dealing with harmful effects due to prolonged administration of drugs—a subject of vast and increasing importance—it is necessary to distinguish:

1. *The direct toxic effect* due to overdose or cumulation and characteristic for each specific drug.

2. *The purely allergic effect* producing affections identical with those seen in consequence of an antigen-antibody reaction in protein anaphylaxis—e.g., serum disease. The illness—e.g., anaphylactic shock, urticaria, asthma—is the same in spite of enormous differences between the causative agents and depends largely on the constitution of the patient.

3. *The allergotoxic effect.*—In many cases an overdose can be excluded and a peculiar susceptibility due to gradual sensitisation of the patient must be assumed; the illness is, however, different from purely allergic reactions and fairly characteristic for the causative drug, which probably acts indirectly through influence on the protein metabolism. Such an allergotoxic effect is responsible for most "drug idiosyncrasies": for cinchophen disease, arsphenamine diseases (dermatitis, hepatitis, thrombopenia),[6] sulfonal hæmatoporphyrinuria, and also for sedormid thrombopenia.

SUMMARY AND CONCLUSIONS

Severe loss of blood-platelets and consequent hæmorrhagic diathesis have been caused by the usual doses of sedormid in certain hypersensitive patients who had received the drug for several months previously with apparently good result.

Repeated administration of a drug may lead to an illness due to sensitisation but unlike the typical purely allergic affections and distinctive according to the chemical nature of the drug: allergotoxic effect.

The modern hypnotics and sedatives are certainly valuable but never absolutely harmless, and careful supervision is required, especially with newly introduced drugs and hypersensitive patients with irritability of the digestive tract.

Cases of "essential" thrombopenic purpura may be traced to drugs even if these have been taken already for some time with no evidence of any ill-effect (arsphenamine, sedormid). If the patient receives a blood transfusion, as Dr. H. Letheby Tidy [7] postulates for all severe cases before splenectomy, time will be gained for closer investigation and an operation perhaps frequently avoided.

THE BRISTOL HOSPITALS.—The overdraft of Bristol General Hospital now stands at £23,575, having been increased last year by £13,000. One-third of the 1933 in-patients (5470) found it impossible to make any contribution to the cost of their treatment. There were over 37,000 out-patients. The pressure upon the X ray, massage, and electrical departments is so great that it is necessary to spend £10,000 in adapting for their use the rooms in the old out-patients' department. In an address at the Lord Mayor's Chapel, Dr. E. J. Glenny said that there are 1000 beds in the Bristol voluntary institutions, each of which costs £5 weekly.

PAPER FILMS IN RADIOGRAPHY[1]

By J. V. Sparks, B.A. Camb., M.R.C.S., D.M.R.E.

CHIEF ASSISTANT, X RAY DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL; RADIOLOGIST, CITY OF LONDON CHEST HOSPITAL

The possibility of the substitution of negative paper for the celluloid film was suggested in a paper read before the British Institute of Radiology in October, 1930, when Dr. J. F. Bromley described and showed examples, mainly in cases of fracture, demonstrating that even minute fractures of the carpal bones were readily distinguishable.

Little more was heard about the paper negative until samples began to appear from Germany about two years later, presumably owing to the fact that the paper was of inferior quality and was an innovation. For it must be realised that in fracture work the radiologist bears a great responsibility in cases where his findings are negative, and it would be a false economy to run the chance of missing a fracture through using what might be considered an inferior article. It was eighteen months ago that I started experimenting with the use of paper films in chest cases at the City of London Chest Hospital for the control of artificial pneumothorax cases.

It was soon found that the emulsion was so sensitive that fogging occurred within a few minutes with the ordinary dark room safe light, but this fault was obviated by placing the negative in the developer immediately it was removed from the cassette. At first it was thought advisable to take a celluloid and paper film of each patient so as to have an accurate comparison between the two. Subsequently, contrary to expectations, it was found that the lung detail in health and disease was so accurately comparable to that obtained on celluloid that I was able to place before the medical committee a scheme for the substitution of celluloid by paper films in certain cases, the object being economy without loss of efficiency.

At this time the English manufacturers came into the market and produced a paper film vastly superior to that supplied from abroad, and the quality of the emulsion has since improved further, and is of a very high standard at the present time. It was found that even greater attention to detail as regards penetration and exposure time was necessary as the latitude of the paper film was very small compared with that of celluloid, and errors of exposure could not be corrected by altering the subsequent development; in fact, if any error of technique was present it was not possible to correct it by subsequent intensification or reduction without spoiling the final result. A poor celluloid film is just poor, but a poor paper film is ghastly.

The paper film has been found to be definitely inferior for use in small children and for adults above the average size; neither has it proved of value for examinations after lipiodol injections where the films are purposely given a greater exposure than normally. Nor has it been found satisfactory for examinations in the oblique and lateral positions. The speed factor of the paper film with one screen shows from 40 to 50 per cent. increase in the exposure time over the celluloid film with two screens, suggesting that the emulsion on the paper film is the faster.

Paper films have been used exclusively at St. Bartholomew's Hospital during the past year for barium meal examinations, and have been found to be satisfactory for patients of normal size, when used in conjunction with a Potter-Bucky diaphragm, or Lysholm grid; they are inferior if used for stout patients or without the grid. I have found that a good paper film when viewed with strong reflected light compares favourably with the celluloid negative when viewed through daylight; it falls short of a celluloid film viewed under proper conditions, and though it will indicate the presence of tuberculous disease it might fail to show the tubercles in the lung which are essential to confirm the radiological diagnosis.

At the Victoria Park Hospital we have arranged for paper films to be taken of all cases, except those mentioned above, unless a request for celluloid is made by the physician. At the commencement of this scheme there was a greater percentage of paper films than celluloid, and now after working for 18 months by this method there are still about 40 per cent. of the chest cases taken on paper. Naturally such films are taken for economic reasons at the discretion of the physician; in a way they are a tribute to the skill of the lay technicians by whom all the radiograms are taken.

I can recommend the use of paper films in chest cases for the anterior view in patients of normal size provided that the apparatus is designed with a fine control of penetration and exposure when results can be obtained within about 10 per cent. of those obtainable with celluloid. They are in everyday use at Victoria Park Hospital—(1) as preliminary films to exclude disease, a celluloid examination being made in any case of doubt; (2) to watch the progress or retrogression of pulmonary disease; (3) in cardiac cases. They are also recommended for the control of the position of fractures where information about the state of union is not required, and for barium meal examinations. I cannot recommend their use in any department where there is no standardisation of technique, or where errors of exposure are controlled in the dark room.

These experiments have been made, primarily for economy, to enable the expenditure in the X ray department to be reduced. To give an idea how real such a reduction has been at Victoria Park Hospital, I may add that we have during the past year increased the number of X ray examinations from 3000 to 4000 without adding to the total film cost, and we hope during the ensuing year to effect an even greater saving through non-duplication. These figures are remarkable when one considers that if there is any query an additional celluloid film is taken.

I might add that the shadows on a paper film are negative shadows, comparable in density to those seen on celluloid, and that reproductions can be made from them equally satisfactorily.

---

[1] Dr. Sparks submitted a series of paper radiograms which compare favourably with celluloid films of the same subject. They are open to inspection at this office.—Ed. L.

Donations and Bequests.—The late Mrs. Edith Anne Thorpe, of Eastbourne, left £3500 to Epsom College and the same sum to the Medical Charitable Society of the West Riding of Yorkshire.—By will the late Mr. Thomas Craven, J.P., D.L., of Kensington Palace-gardens, London, left £1000 to the Manchester Royal Infirmary; £500 to the Salford Royal Hospital; £500 to St. Mary's Hospital, Manchester; £500 to the Hospital for Consumption, Manchester; £500 to the Manchester Children's Hospital; £500 to the Northern Counties Hospital for Chronic and Incurable Diseases; and £500 to the Belgrave Hospital for Children.

MEDICAL SOCIETIES

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM

THE annual congress of this society took place at the house of the Royal Society of Medicine from April 12th–14th, under the presidency of Mr. M. S. MAYOU. A discussion on the

Surgical Treatment of Unusual Forms of Squint and Heterophoria

was opened by Mr. Mayou, who dealt with a selection of cases from a series of 700 operations for squint. No ophthalmic surgeon, he said, had had many cases of the rarer forms of squint, and as the results were not generally known, there was a natural hesitation to operate at all for fear of making the condition worse, as might easily happen if the operation were faulty or done at the wrong period of life. Even such a common condition as hyperphoria was seldom operated upon in this country. He used the old method of tenectomy with advancement, so that he could see what he was doing. Provided the muscles were *not* pulled upon it was practically painless; he had done tenotomies in children of 3 years, and tenectomy in children of 5, without an anæsthetic. But he did not object to operating under an anæsthetic if the patient had good vision in both eyes and possessed a sense of fusion. When the patient was not under an anæsthetic the result was controlled during the operation by the Maddox rod test, with a light set in the ceiling of the theatre. In doing either tenotomy or tenectomy he did not separate the tendons from Tenon's capsule, as it gave a firm hold for the sutures, which were then not so liable to cut out. He used Japanese fishing gut, which was soft and easy to pull through. Low degrees of hyperphoria were treated by prisms; high degrees (which were accompanied by diplopia or torticollis) by tenotomy of the superior rectus. Speaking of partial tenotomy, Mr. Mayou said that unless the tendon was completely divided there was practically no result; he always inserted a tenotomy hook to make sure this had been done. For tenectomy he used the three-stitch method. When it was desired to increase the effect of the advancement the sutures should be placed further back, through capsule and tendon. The opposing muscles should be tenotomised in every case, partly in order to increase the effect, but in any case to weaken temporarily the muscle and so obviate traction on the sutures. Complete rest to the muscles was ensured by bandaging both eyes for seven days after operation.

Diplopia occurred in association with what was apparently a concomitant convergence in late syphilitic lesions of the central nervous system. It resembled that met with in encephalitis lethargica as it was always divergent. It was due, he thought, to a lesion of the convergence centre in the brain; he had seen four such cases between 35 and 45 years of age. Cases of ocular torticollis with hyperphoria were eminently suitable for operative interference, because if the hyperphoria was corrected, stereoscopic vision resulted immediately, and the head was brought to the normal posture. Congenital defect of external recti might occur on one or both sides, and was usually associated with convergence. Some unilateral cases might be due to a birth injury. There were two groups: one associated with enophthalmos, in which the internal muscles and the check ligaments appeared to be bound down on the inner side of the orbit; the other without enophthalmos. It was important to operate on these cases early in life; if they were left until later, diplopia resulted from the operation. Of three cases operated on by tenotomy and advancement, in two the eyes were straightened but no outward movement occurred. In the other case the muscle which was being held in the forceps was felt to contract, and there was a slight return of outward movement later. In one unilateral case with extreme convergence, good movement was obtained by operation.

Dr. BERNARD CHAVASSE, in an exhaustive review of the subject, asked members to pool their experience, poor as well as good. One lesson he had learned was the extreme importance of careful diagnosis. He dealt with 29 cases of unusual forms of squint, demonstrating by means of slides the particular treatment employed. There was, he said, a good deal of similarity between cases of congenital abducens palsy and those of so-called essential alternating convergence due to a total absence of the fusion faculty. In cases in which the abducens palsy was very slight much could be done by superimposing ordinary concomitant convergence. In young children benefit followed rotation of the head away from the paretic abducens, at the same time stimulating conjugate deviation. He spoke of fusion and the stereopsis found in alternating squinters.

Mr. W. H. MCMULLEN said that in most forms of congenital paretic strabismus the best results were obtained by tenotomy or recession of the chief opponent to the affected muscle, in some cases with advancement of the weak muscle. Where the oblique muscles were concerned it was impossible to alter the position of attachment of the tendons to the globe. For paresis of the superior oblique three methods of operation merited consideration. The first was division of the inferior oblique of the same side close to its point of origin. Doyne, in 1926, reported two cases of ocular torticollis in which he had done this, with marked improvement in one, little or none in the other. Temple Smith recommended not merely division of the muscle, but excision of a portion, and he claimed excellent results in torticollis. Mr. McMullen had not attempted it, chiefly because of the impracticability of controlling the result. The second method was displacement of the insertion of the tendon of the superior rectus of the same side. In 1903 Jackson described an operation for outward and backward displacement of the insertion in order to increase the power of intorsion of the muscle, while lessening its power of superduction. Years ago Mr. McMullen did this operation on a boy who had marked torticollis, but the result did not satisfy him, though the mother expressed her pleasure at it. The third method was tenotomy and recession of the inferior rectus of the opposite side, favoured by most writers on the subject. The setting back of this tendon compensated fairly well for the weakness of the superior oblique on the other side. It was possible to combine this operation with an advancement of the superior rectus, the result of which could be controlled.

Sir RICHARD CRUISE spoke of six cases of unusual type which he had dealt with, and in which the results had lasted 20 to 30 years. One case he saw in 1910 on account of long-standing hyperphoria of high degree; as refraction was normal he did not operate, but the patient returned in 1913 begging that something might be done. Accordingly he performed tenotomy of the superior rectus and put in a retention suture. A month later there was an excellent cosmetic result, but the trouble did not end. A prism stereoscope was supplied and exercises given for fusion, as there was cyclophoria. A few days ago he had seen this patient who was practically cured and quite happy. Another case was one of divergent strabismus of 16 years' standing. There was no attempt at fusion before operation in 1918. A slight operation with fusion exercises restored binocular vision, and she had remained happy. He concluded by paying a warm tribute to the work of Claude Worth in this domain.

Mr. **Humphry Neame** reported a case of upgoing eye in adduction in a girl 4 years of age, in whom the difficulty improved almost to disappearance in a few years, so that it was hoped it would eventually go entirely without treatment beyond the correction of the error of refraction. He also spoke of the case of a girl aged 22 who had a history of squint dating from infancy. At 3 years of age an operation was done on the eye, the nature of which was not known. Last year when seen she had a right convergence of 10°, which was concomitant, and the right eye went upwards 20°; the upward deviation increased when she looked to the right. With this eye vision was restricted to finger counting at 2 ft.; the vision of the left eye was 6/6. In December he did a right tenotomy of the superior rectus, and in January a right advancement of the inferior rectus. After the second operation, instead of being 20° up in the middle position looking forward, there was 10° in the right eye, with 5° convergence. In March he did an advancement of the right inferior rectus and a recession of the internal rectus. Recent photographs showed great improvement. He had had other similar cases.

Mr. **F. A. Williamson-Noble** related a series of cases of unusual squint, among which was that of a woman aged 24, whose refraction was practically emmetropic. He decided to do a recession of the inferior rectus, putting the muscle back 2 mm. Three weeks later, when she looked straight ahead, with the Maddox rod she was practically orthophoric, and in that state she had since remained. Another case was a man aged 56 with paralytic squint, following a fracture of the base of the skull. The condition had lasted 15 years, and although the external rectus seemed to be the only paralysed muscle, such marked secondary contraction had occurred in the internal rectus that the eye was drawn in towards the canthus, and was useless for purposes of vision. Operation was not urged; an eye was painted on the back of his glass.

Dr. **George Young** (Colchester) reported a case of extreme vertical imbalance in a woman aged 44, whose complaint was of lacrymation and left frontal headaches. No organic changes were detectable in the fundi, but the left optic nerve was less developed than the right. She had considerable left hypophoria. He prescribed constant bi-focal correction, but a few months later serious discomfort was reported, with lacrymation and photophobia, and occasional diplopia while in the street. Many other measures were tried, and eventually the eye was excised, after tenotomy had failed. It was found that the diplopia was produced by the subsequent formation of fibrous bands, which frustrated the initial good result of the tenotomy. She remained greatly benefited by the enucleation.

Mr. **P. G. Doyne** agreed that slight cases of ocular torticollis were not uncommon, and for them no treatment should be precipitately attempted. But in some cases the deformity was so marked that secondary postural deformities arose, and it was necessary to do something operative. In his own hands tenotomy of the inferior oblique had been, on the whole, satisfactory. It was important that these cases should be recognised outside ophthalmic circles, so that appropriate control could be given from the beginning.

Mr. **Lewis Savin** spoke of his treatment of eight cases of paralytic strabismus by operation. Before operating he required assurance that: (1) the diplopia was so troublesome that the eye was kept covered; (2) it had persisted a long time without improvement; (3) a neurologist had advised that no further improvement was to be expected; (4) the patient was told the operation was only palliative. He had found patients grateful for what seemed objectively only small improvement.

Mr. **D. V. Giri** and Mr. **M. Hepburn** also described unusual cases of squint on which they had operated.

Among the many individual papers read at the congress only a few lend themselves to brief abstract.

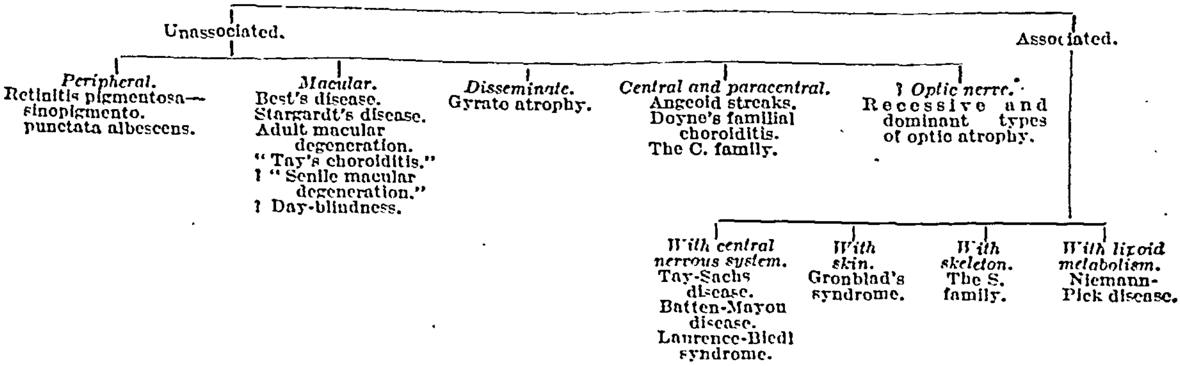
PULMONARY EMBOLISM FOLLOWING OPHTHALMIC OPERATIONS

Mr. **E. Wolff** suggested that there were many more cases than the literature would leave one to suppose. He discussed current theories on the causation of pulmonary embolism generally, and concluded that the operation on the eye per se has probably nothing to do with it. Finally he described a case which he thought might help to throw some light on causation.

RETINAL ABIOTROPHY

Mr. **A. Sorsby** began with Paget's conception of "premature degenerations . . . diseases only in consideration

RETINAL ABIOTROPHY



of the time of their occurrence" (1853), and Gowers's definition of abiotrophy (1902). He compared the modern application of terms dystrophy and abiotrophy, hereditary ocular degenerations of Treacher Collins (1919–20), "ophthalmic abiotrophies" with Leber's concept of tapeto-retinal degeneration (1916). He then attempted a classification of his own (see Chart).

ATROPINE IRRITATION AND ITS PREVENTION

Mr. R. G. WALLER discussed atropine irritation from the clinical point of view. Sensitivity to atropine presents certain aspects not unlike the phenomena known as allergic. So far as is known there can be no true allergy in connexion with a pure alkaloidal salt such as atropine sulphate, since allergic phenomena are associated with proteins. The possibility of a chemical or physical combination between atropine sulphate and the proteins of tears was suggested, with a rational line of therapy based on this assumption. A technique was described for the preparation of a solution of the alkaloid in human tears with a view to obtaining an alkaloid-protein combination to be used as a desensitising agent, and an account given of the therapeutic effects obtained in a series of 30 cases.

CALCIUM AND PARATHYROID THERAPY IN PROGRESSIVE MYOPIA

Mr. F. W. LAW set out the results of this treatment in a group of 27 myopes, between the ages of 6 and 14 years, discovered amongst 1300 sent for refraction to a municipal clinic. They were all proved to be progressive by observation for at least 12 months before treatment was begun, and no conclusion was drawn until 9 to 12 months of treatment had been given. The cases were divided into five categories. The majority of cases responded favourably: of 17 who satisfied all the conditions 13 showed definite benefit, and the use of the drugs should be given a prolonged trial in cases of this serious disease.

REPRESENTATION OF THE RETINA IN THE GENICULATE BODY

Mr. G. PENMAN gave the evidence, derived partly from animal experiments and partly from observations on pathological conditions in human beings, of the representations of the areas of the retina in the lateral geniculate body. This geniculate body is arranged in laminæ of cells, in which the optic nerve-fibres terminate, those from the same and from the opposite side going to different laminæ. The macular area is more restricted than previous observations have suggested, and is represented by a median sector which is definitely limited to the caudal two-thirds of the nucleus. It involves all the cell laminæ. Fibres from the nasal half of the macula undergo complete decussation in the chiasma, while those from the temporal half remain uncrossed. The whole width of the cell laminæ in the oral third of the nucleus is concerned with peripheral vision. The upper part of the retina is represented in the medial portion of the nucleus, the lower in the lateral portion, as stated by Brouwer and Zeeman.

HETEROPHORIA IN AVIATION

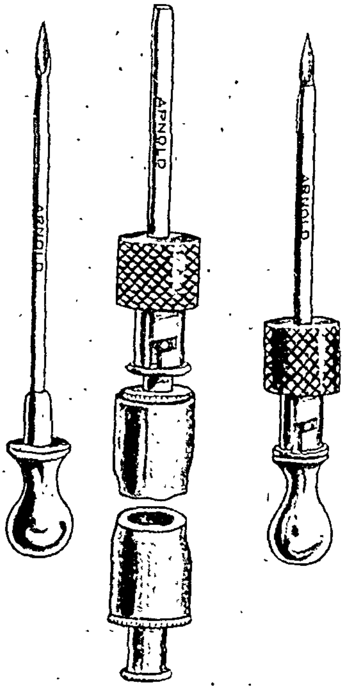
Squadron-Leader P. G. LIVINGSTON spoke of the importance of visual judgment in modern flying. The manœuvring speed of aircraft is increasing year by year, and though the landing speed is kept within certain limits by various mechanical devices, it is, with the passage of time, becoming definitely greater. Heterophoria is an outstanding cause of errors of judgment in landing. The condition may develop in the borderline cases admitted while they are undergoing flying training, or it may come about as a complication of head injuries with concussion, with a marked convergence weakness as is commonly shown. It may result from the effects of illness, or through continued exposure to sun glare. The training of cases so suffering by amblyoscopic and stereoscopic exercises has shown that, with care in selection, over 90 per cent. of cures have been brought about.

ALDERSHOT MATERNITY UNIT.—Lady Isobel Gathorne-Hardy, wife of the general officer-in-chief, Aldershot Command, recently opened a maternity unit which has been added to Aldershot Hospital. The building includes eight wards, several private wards, and a creche.

NEW INVENTIONS

A TROCAR AND CANNULA FOR THE INJECTION TREATMENT OF HYDROCELE

THERE are numerous types of trocar and cannula used for tapping hydroceles, but the one which I have had specially adapted for my own use has proved both practical and satisfactory. It consists of a trocar and cannula, made in two sizes (the large size equal to a 10 S.W. gauge, and the small size equal to a 12 S.W. gauge), and a rubber connexion piece with special bayonet fitting mount. The trocar and cannula is introduced into the hydrocele sac, and the finger-piece is firmly grasped between the thumb and index-finger of the left hand. The trocar is then withdrawn. After all the fluid in the hydrocele sac has been evacuated a 10 c.cm. syringe is charged with a suitable solution and attached to the cannula by means of the rubber connexion. This connecting piece allows of a certain amount of flexibility in the manipulation of the syringe during the process of injection. At the completion of the injection the cannula is removed and the parts are massaged.



The trocar and cannula is made for me by Arnold and Sons (John Bell and Croyden), 52, Wigmore-street, London, W.

RODNEY MAINGOT, F.R.C.S. Eng.

ABERDEEN ROYAL INFIRMARY.—The total cost of the new infirmary being built at Foresterhill is now estimated at £484,000, and since the building fund falls short of this amount by £72,000, it has been decided to reopen the appeal for money. It had been intended to provide 580 beds, but the number has had to be reduced to 500. Last year the infirmary received 6709 in-patients and treated 25,000 out-patients. The average daily number of beds occupied was 379, and the average stay 21 days.

ADULT CONVALESCENT HOMES FOR LIVERPOOL.—At the annual meeting last week of the Children's Convalescent Home at West Kirby, Dr. W. M. Frazer, medical officer of health for Liverpool, stated that the matter of convalescent accommodation had not been satisfactorily dealt with in that city. Seeing that most of the voluntary and municipal hospitals in Liverpool are in overcrowded and built-up areas, where the air is unsatisfactory, and where comparatively little sunlight can enter most of the rooms, he was satisfied that convalescent homes were desirable for adults as well as children.

REVIEWS AND NOTICES OF BOOKS

Obstetrics and Gynecology

Edited by ARTHUR HALE CURTIS, M.D., Professor and Head of the Department of Obstetrics and Gynecology, Northwestern University Medical School. London and Philadelphia: W. B. Saunders Co. Ltd. 1933. Vols. II. and III. Pp. 1135 and 1201. In complete sets of 3 vols., £8 5s.

THE completion of this fine compilation on obstetrics and gynæcology will be welcomed by those who studied the first of the three volumes, reviewed in our columns in September last. That volume dealt with history, anatomy, embryology, physiology, normal pregnancy, and labour, and made a start in the consideration of pathological conditions in pregnancy. Though the clinical chapters reached a standard rather less high than those on morphology and physiology, which were of outstanding merit, the reader was left with a keen desire to possess the two succeeding volumes.

These have now appeared and deal with the pathology of labour and the puerperium, and with gynæcology. The selection of a large number of authors, each writing on a small section of the subject, is, as we anticipated, more successful in the section of the work allocated to gynæcology, which lends itself to this treatment better than does obstetrics. Many men of world-wide repute are among the authors, and the chapters on endocrinology seem to us the most important and valuable feature of the whole work; Edgar Allen writes on theelin, G. W. Corner on the corpus luteum, P. E. Smith and E. T. Engle on the anterior pituitary secretion, and Emil Novak correlates the scientific work with clinical conditions in chapters on gynæcological endocrinology, uterine hæmorrhage, amenorrhœa, and the menopause. These chapters give much important information which is not to be found in the ordinary general text-book. The subjects of clinical gynæcology are also dealt with thoroughly and efficiently, and the long list of references to the literature at the end of each chapter serves the needs of students who wish to consult the original papers on the subject. The section on sterility by I. C. Rubin, and those on roentgenography by James T. Case, and on radiotherapy by Curtis F. Burnam, are worthy of special mention. There is a little overlapping in places: for example, illustrations of reconstruction of the urethra appear in the chapter on prolapse as well as in that on fistula. The chapter on prolapse is not good; it gives little description of the condition, and is mainly devoted to operations for its cure, though the work of Donald and Fothergill is ignored. In the chapter on blood transfusion space is wasted by the inclusion of detailed description of cases of non-gynæcological conditions treated by this method, some of them being males.

Obstetric operations are described by a number of authors. In our view there was no need for a separate chapter on episiotomy, which does not even mention lateral episiotomy, preferred by many to the central incision. The chapter on puerperal sepsis, by B. P. Watson, gives an excellent account of the pathology and treatment. In some other conditions, such as accidental hæmorrhage and contraction ring, the descriptions of the pathology are inadequate for a book of this size. The methods of treatment recommended are sometimes not in accord with English practice; for instance, uterine drainage and injection of glycerin for sepsis are condemned.

The book is well illustrated, both from the pathological and operative standpoints, with numerous photographs and diagrams. Each volume has an index and a separate index covers the whole work. Altogether a worthy production.

The Science of Radiology

Edited by OTTO GLASSER, Ph.D., Cleveland Clinic Foundation. London: Baillière, Tindall and Cox. 1933. Pp. 450. 25s.

THIS interesting volume has been produced in connexion with a successful radiological congress held at Chicago during the Fair of 1933, in which the five main American radiological societies collaborated.

Dr. Otto Glasser, whose "Life of Roentgen" was recently reviewed in these columns, acted as editor, and has contributed authoritative chapters on Roentgen and the Curies and their discoveries. The remaining 23 chapters by different experts cover the whole field of radiology. All, within the very circumscribed limits, are good. Practically every phase of radiology is dealt with—technique, dosimetry, diagnosis, physics, biological effects. X ray cinematography is apparently destined to play a large part in the scientific investigations of biological problems, and the author of this section, H. A. Jarre, has summarised well the attempts made to solve the technical problems concerned. The section on the teaching of radiology, by J. T. Case, is well worth study. G. M. MacKnee deals with cutaneous X ray and radium therapy. We would commend this section to those who have been so engrossed in investigating the effects of radiation on malignant disease that they are inclined to overlook the considerable field of usefulness for these rays in non-malignant conditions, and more particularly in dermatology. Those who are interested in the borderlands of radiological work will find satisfactory chapters on ultra-violet and infra-red radiations, cosmic rays, and Gurwitch rays.

This book provides a worthy memento of a successful congress.

Four and a Half Years

A Personal Diary from June, 1914, to January, 1919. By the Rt. Hon. CHRISTOPHER ADDISON, P.C., M.D., F.R.C.S. Vol. II. (1917–19). London: Hutchinson and Co. 1934. Pp. 629. 18s.

THE first volume of Dr. Addison's record of the war years was reviewed here on its appearance at the beginning of the year. The second volume is now issued and completes the author's personal story of the most critical period of our national history, during which the diarist was in succession head of two great bureaux, the Ministry of Munitions and the Ministry of Reconstruction. The story ends with the significant episode of the dissolution of the Local Government Board when Dr. Addison was appointed the first Minister of Health.

This volume is not easy reading, and how should it be, as it contains the description of the formation and activities of the main Government departments while the fortunes of the country fluctuated during the last 18 months of the war? The interplay of events and personalities is extremely difficult to follow and, from the medical point of view purely, it is not worth following. Dr. Addison deals with the reactions of various important public men to proposed official changes, to methods for making increasingly effective designs both of offence and defence, and to general plans for reconstruction at the end of the struggle. Such chapters as those which set out the emergency problems at home, the complications of the Irish question, the preparations for demobilisation, journalistic interventions and election machinery have no special medical message except what may be extracted from their psychological interest, and this is of a somewhat painful character in view of certain revelations or allegations. It is an unfortunate fact that Dr. Addison should have received not infrequently unfavourable impressions of the work of some of his colleagues. In the references to food control it is curious that little or nothing should be said conspicuously about the influence which the scarcity of food had on public health, but for Lord Rhondda's courage and energy Dr. Addison has frank words of praise.

Dr. Addison's two large and detailed volumes—and the details are indeed voluminous—do not form a war diary, but they give an inside view of the conduct of material affairs during the war period. As such they afford valuable information, and if little or none of it is of close medical interest, it must be recalled that the years of the narrative correspond with a break in the author's direct work in medical fields. The entries cease just before Dr. Addison's appointment as first Minister of Health, an appointment which may be regarded as consequent upon his pre-war activities, which, in connexion with the National Insurance Act, had been of first-class medical importance.

Red Medicine

Socialized Health in Soviet Russia. By Sir ARTHUR NEWSHOLME, K.C.B., M.D., and JOHN ADAMS KINGSBURY, LL.D. London: William Heinemann (Medical Books) Ltd. 1934. Pp. 324. 10*s.* 6*d.*

THIS book was noticed at some length in THE LANCET by an American correspondent at the time of its recent issue in the United States. It is a responsible account of Russian public health administration under the Soviet Government, and its message is to suggest that Soviet ideas are providing medical and hygienic service in accordance with the socialistic views of the Government. The book is now published in England and will interest all students of sociology and workers in public health and welfare directions.

Introduction to the Vertebrates

By LEVERETT ALLEN ADAMS, Assistant Professor of Zoology, University of Illinois. New York: John Wiley and Sons Inc.; London: Chapman and Hall Ltd. 1933. Pp. 414. 21*s.* 6*d.*

THIS book, divided into three parts, deals first with the characteristics, phylogeny, and classification of the chordates, including fossil forms. Nearly fifty illustrations of representative types serve to make the classification something more than a long list of names. In the second part the five main divisions—i.e., fishes, amphibians, reptiles, birds, and mammals—are described anatomically with a view to giving the reader an outline of the morphology of the types, very little detail being supplied. In the third section the various tissues—e.g., the integument, the skeleton, the muscles—are discussed in considerable detail, typical examples of the various classes being compared in order to emphasise evolutionary development. This method of treating the subject has considerable advantage in that the student can either skim over it or delve deeply; it carries the risk, however, that the knowledge acquired will be rather disjointed. Numerous illustrations are included in which essential features are emphasised and artistic detail is omitted.

To anyone wishing to study the vertebrate without any previous knowledge of biology this book may be recommended.

Pharmacopœias and Formularies

A Compendium of the Pharmacopœias and Formularies (Official and Unofficial), with Practical Aids to Prescribing and Dispensing. Seventh edition. By C. J. S. THOMPSON, M.B.E., Hon. Curator, Historical Section, Royal College of Surgeons of England. London: John Bale, Sons and Danielsson Ltd. 1933. Pp. 381. 10*s.* 6*d.*

THE title of this work gives a fair idea of its scope. It contains a list of official and unofficial modern remedies with their solubilities, properties, and doses; synopses of the British and foreign pharmacopœias; useful formulæ selected from the B.P.C., hospital pharmacopœias, formularies, and other sources; stock mixtures, preparations for the feet, nasopharynx, and the toilet; notes on invalid foods, antiseptic dressings, the treatment of burns, and on medicated baths; and memoranda on bacteriological work in relation to medicine—on urine and milk analysis, and on sterilisation. Information is also given regarding the Poisons and Pharmacy Act, the Dangerous Drug Regulations, incompatibilities, and antidotes to various poisons. There are included an index of diseases and the various remedies which have been employed in them; and numerous tables, one giving the doses of the commoner drugs used for animals in veterinary practice. The work has been brought up to date, and should continue to prove a handy book of reference for the busy practitioner.

Lord Lister

By C. J. S. THOMPSON, M.B.E. London: John Bale, Sons and Danielsson Ltd. 1934. Pp. 96. 5*s.*

THIS short book has been written to supply general readers and students with a brief account of the career of the founder of aseptic surgery. We have details of his life as a student at University College Hospital and as an interne at the Royal Infirmary, Edinburgh; sketches of surgery before the antiseptic era; and an interesting account of how Lister's previous work led up to surmises and convictions, experiments and success. The sketch closes with an estimate of Lister as a benefactor to humanity. As hon. curator of the historical collection in the museum of the Royal College of Surgeons of England, Mr. Thompson was in a happy situation for adding, as an appendix, a guide to the collection at the College of relics, instruments, documents, and manuscripts relating to Lister. The author acknowledges his indebtedness to Sir Rickman Godlee's well-known biography, and has been happily inspired in his desire to make Lister's story available in this brief form.

ERRATUM.—In a review published in our issue of April 7th, p. 740, Mr. Alan Macey was incorrectly described as "M.D." We regret the mistake.

Rheumatism—

both articular and non-articular—is helpfully treated with packs of Antiphlogistine Dressing, because of the prolonged moist heat which they supply and because of their analgesic and anodyne qualities.

The application of heat to a part and the induction of hyperaemia, tend to improve the general metabolism, promote absorption of the swellings in and around the joints and muscular fibres, and to reduce the thickness of the synovial sacs, so that morbid articulations assume a more normal shape.

Antiphlogistine Dressing is a valuable adjuvant in the treatment of rheumatic conditions, where the application and maintenance of moist heat is so helpful.

ANTIPHLOGISTINE
BRAND DRESSING

for Pain and Inflammation

● **uterus, vagina and breasts rapidly developed** ●

The œstrogenic hormone Menformon induces uterine growth; thickening of vaginal stratified epithelium; œstrus . . .

Menformon is indicated in uterine hypoplasia, vaginal inflammation, alopecia, prematurity of infants, operative menopause, frigidity . . .

Biologically tested before issue it is supplied in aqueous or oil solution, tablets or pessaries.

SUPER STRENGTH 10,000 *International* UNITS PER C.C.

MENFORMON

PERCAINE "CIBA"

Trade Mark Registered.

The New Local Anæsthetic for Regional, Infiltration, Surface and Spinal Anæsthesia

Acts in extreme dilution (0.5-2 : 1000).

Produces anæsthesia of hitherto unattained intensity and duration.

Not a narcotic. Economical in Use.

Belongs chemically to a class entirely different from cocaine and its derivatives.

RESISTANCE TO STREPTOCOCCAL FIBRINOLYSIS IN RHEUMATIC CHILDREN

It is not yet generally known outside laboratory circles that a new property has recently been demonstrated in pyogenic streptococci which may have an important bearing on their activities within the body. This is the formation of a substance which liquefies fibrin, and it is not difficult to picture the contribution which the activity of such a substance may make to the rapid extension of acute streptococcal lesions. Although the solution of fibrin by streptococci was first observed some years ago in slide cell plasma cultures at St. Mary's Hospital by R. M. Fry, the significance of this change was not then appreciated, and it has been left to W. S. Tillett and R. L. Garner,[1] working at the Johns Hopkins Hospital, to study the phenomenon in detail. The main facts established by these authors are that coagulated human plasma is liquefied, usually within a few minutes, by cultures of *Streptococcus pyogenes* from a variety of human sources, or by filtrates of such cultures; on the other hand, streptococci of animal origin are usually incapable of inducing this change, and animal fibrin is resistant to it. No other bacterial species has been found capable of this fibrinolysis; it is an effect which, as far as we know, is confined to streptococci of human origin acting on human fibrin. A further observation of great importance, recently investigated by Tillett, Edwards, and Garner,[2] is that recovery from acute streptococcal infections, exemplified by scarlet fever, tonsillitis, otitis media, and sinusitis, is accompanied by the development of resistance to fibrinolysis, the patient's coagulated plasma remaining solid for hours, or throughout the maximum period of the test, in the presence of a streptococcus culture which lyses normal plasma clot within a few minutes. The development and subsequent decline of this resistance was studied by repeated examination of the blood, and shown to be a specific change by the negative results of similar observations in cases of non-streptococcal disease. Since recovered case serum confers resistance to lysis on normal plasma, it may be assumed that the property of resistance is due to the formation of an antibody.

We print on p. 834 of our present issue an article by Prof. Geoffrey Hadfield and his co-workers, in which these observations are confirmed and extended in new directions. The first of these concerns variation in the fibrinolytic power of streptococci and its relation to their other characters. Such variation was considerable, and suggested subdivision of the strains studied into three groups, according to the time required for fibrinolysis under standard conditions. This grouping corresponded broadly to the degree of severity of the infections from which they were derived, and to the degree of virulence for mice, rapid fibrinolysis being an attribute of the more virulent strains. It was found further that these strains formed colonies of rough or matt appearance, whereas smooth (glossy) strains were weakly fibrinolytic; degradation of matt strains after repeated subculture to the glossy type was accompanied by partial loss of fibrinolytic power. It appears, therefore, that capacity for fibrinolysis goes hand in hand with virulence and "roughness." The further studies reported in this paper concern the nature of resistance to fibrinolysis, and include what appears to be a conclusive demonstration that this resistance is developed by patients suffering from rheumatic fever. It will be remembered that E. W. Todd demonstrated[3] the presence in the blood in this disease of an antibody which neutralises the hæmolysin of the streptococcus, an antibody which also appears after acute infection known to be streptococcal, and is present only in smaller amounts in the blood of unaffected subjects. This observation has since been repeatedly confirmed, and is perhaps the strongest evidence we have in favour of the streptococcal origin of acute rheumatism. What Prof. Hadfield and his colleagues at Bristol have done is the equivalent of Todd's work in the new field of fibrinolysis, and it must be granted the same significance. This method may prove a useful new weapon with which to attack the unsolved problems of acute rheumatism. Of the study of the action of streptococcal products on fibrin, both as an in-vitro phenomenon and as it concerns the progress of natural infection, and of antifibrinolysin, the name by which the newly discovered antibody will presumably have to be known, we shall no doubt hear much more before long.

What may appear in this connexion a somewhat confusing observation has also been made by Tillett and Garner[4]—namely, that certain strains of streptococci are highly agglutinable by normal plasma, the active element in the latter being either its fibrinogen (chemically isolated fibrinogen exerting the same effect) or a protein closely related to it. This observation is of some interest as illustrating a form of entirely non-specific agglutination, but since the substance responsible may apparently be formed in excess in the early stages of acute infections of many kinds, and is also present in the separated serum, it affords a warning against too ready acceptance of agglutination tests as evidence of streptococcal activity in any acute febrile state.

SPECTACLES OF CRUELTY

Doubts on the propriety of public exhibitions involving physical suffering have of late been given considerable prominence in Parliament and elsewhere. Films showing fatal accidents, both by car and aeroplane, admittedly indicate a triumph of modern enterprise and technique, but their display to the general public offends people whose sentiments—perhaps old-fashioned—make them abhor the thrill associated with such sights, though the exhibitors of the films may rely upon just that thrill as a popularising element. Apart from the matter of cultivation of taste—which in any event tends to vary from generation to generation—it is difficult to specify what harm could result from such a show, except possible damage to nervous people by stimulating unpleasant ideas or by exacerbating symptoms. The acceptance of an arbitrary standard of good taste as a criterion of censorship might be really only a concession to squeamishness or taboo, both of them potent factors in the production of unhealthy reactions. But other than good taste is often involved; as, for example, in some pretended jungle films portraying animal fights to the death, in which there is more than a suspicion that the fight is a staged episode that would never occur naturally. Two fresh considerations arise here: first, the infliction of pain and terror, the objection to which rests upon something more absolute than good taste and yet, like that, is dependent rather upon emotion than argument, the final sanction for its prevention being that the deliberate infliction of suffering upon animals is repugnant to most of us; secondly, there is the danger of stimulating tendencies to cruelty—a very real danger. The word sadism has passed into our common speech; the existence and nature of that aberration is generally if only partially recognised, and it is noteworthy that little official censorship is exercised over publicity that directly appeals to it. Censorship over details of normal sexual behaviour is still exercised and is occasionally defended by the assumption—not often specifically formulated—that their publication would lead susceptible readers to embark precipitately upon action that, whilst within the limits of the biological norm, would be socially undesirable. That harmful sadistic behaviour may be stimulated, or that sexual impulses of a sadistic nature may find gratification, by details or actual exhibitions of cruelty, is well known to psychopathologists who, if given the power, might exercise a censorship in unexpected directions.

[4] Bull. Johns Hopkins Hosp., March, 1934, p. 145.

There is, we are told, a sadistic component in all of us. Indeed, an excessive reaction against cruelty is, with the usual contrariness of psychoanalytical theory, ascribed to over-compensation of that component. Differences of opinion with regard to the necessity of war depend fundamentally upon differences with regard to the possibility of directing this element of human nature. The satisfaction of the aggressive impulse is provided for in our social organisation with the purpose, generally undefined but nevertheless present, of turning it to desirable or at least harmless ends. Not as a matter of good taste but as a matter of policy it is surely proper to seek to prevent exhibitions that may foster the tendency to cruelty that exists, overt or latent, in mankind. We therefore support the protests being made in Parliament against the proposed repetition of the rodeo exhibition in this country. This involves obvious cruelty to beasts which, being stabled, are pitiful substitutes for the semi-wild cattle whose handling may call for such methods; and here it should be mentioned that in the cattle country of Australia such methods are unknown, though exhibitions of drafting and cutting-out cattle are attractive additions at country shows. Cruelty to the bucking horses is not so obvious to the spectator as are the broken legs and horns of the cattle, but whereas the successful conquest of a genuine buck-jumper is a performance that legitimately satisfies the aggressive tendencies of performer and onlooker, it is common knowledge to Australian bushmen that no stabled horse retains the habit, which can be reproduced only by the use of severely painful measures. The association of cruelty with rodeo performances is undoubted. Some spectators may obtain satisfaction for their sadistic trends from the thrill they experience in watching them. Let us hope at least that, if the performance is after all permitted, the ultimate result will be only satisfaction and not stimulation.

THE RECOGNITION OF CHIROPODY

AT a Council meeting of the British Medical Association held on April 4th an interesting debate centred around the question whether chiropodists, approved in accordance with a clearly defined range of duties, should be accorded a measure of professional recognition. Chiropodists possess an official representative body, and the desire for recognition emanated from them, while already there is at least one hospital in London, known simply as the Foot Hospital, where cases are under treatment which conform to the definition, popular or scientific, of chiropody. On the question of professional recognition arising, inquiry was made by the British Medical Association of the Incorporated Society of Chiropodists with the result that the following definition of chiropody was mutually agreed upon: "Chiropody means the treatment of abnormal nails, and all superficial excrescences occurring on the feet, such as corns, warts, callosities, and bunions." It was further agreed that not even within that field should chiropodists operate for deformities, or treat any condition either involving tissues below the skin level or requiring general or local anæsthetics. Subject to the definition and the reservations the Ethical Committee of the B.M.A., to which body the questions were referred, reported in favour of recognition.

Dr. LANGDON-DOWN, in proposing the acceptance of this report by the Council, pointed to the modern developments in the field of chiropody, to the rise of institutional treatment, and to the fact that the sphere of therapeutic action under discussion had been left vacant in medical practice. It must be remembered that no discussion of the proposed field of work could take place in the Council, as definition of chiropody and the limitations of its scope had already been agreed upon between the B.M.A. and the representative body of the chiropodists. On that agreement the report had been framed, so that the obvious difficulties of including such a complaint as a bunion inside the domain of dermatology could not be discussed;

the Council were asked to register an opinion on the general situation as set out by the report. The measure of recognition suggested in the document was definitely objected to by certain members of the Council on the ground that no person who had not passed through a medical curriculum could be held as competent to diagnose and treat disease; and as the main significance of the Medical Act lies in the provision to the public of knowledge whether a practitioner has passed the necessary educational tests for registration, the objection was obviously forceful. But the old difficulty remained for consideration as to how far therapeutic procedures ancillary to professional medical treatment can be regularised, seeing that these procedures are, if properly guarded, of obvious public utility. Sir HENRY BRACKENBURY, speaking from the chair, set out the position, as he saw it, succinctly. What was he to do, he asked, if a person came to him with a bunion which he did not care to treat? He considered it common sense that such sufferers should go to the chiropodist, and as the chiropodists possessed a representative body with which certain well-known surgeons were associated, it was reasonable that they should receive the measure of recognition asked for.

The crux of the situation must have seemed to the Council to be the fact that support was already afforded to organised chiropody by the medical profession, for the Council agreed by 16 votes to 12 to recommend to the Representative Body that the defined measure of recognition should be given to the chiropodists, a decision being also reached, by 17 votes to 8, to refer back to the framers of the report a recommendation to include within the National Register the names of members of approved organisations who practise chiropody.

THE BUDGET

THE past year, and especially the past few months, has seen a better understanding of poverty and a greater sympathy with the poor. More and more people have come to realise that unemployment is no crime—that nowadays the means of livelihood are distributed less according to merit than according to the wayward working of economic machinery which has partially broken down. Authoritative reports on housing and feeding have worked on the public mind in such a way that there will be a widespread feeling of relief that Mr. CHAMBERLAIN's Budget has first of all restored to the unemployed the full rate of benefit reduced in 1931. Much of the bitterness of discussions on the Unemployment Bill could have been avoided if this concession had been announced as soon as last year's surplus became certain: and the scale, with its continuing 2*s.* for each child, remains inadequate for maintenance over long periods. But the change, which comes into force in July, will allow the new Unemployment Assistance Board to adopt a more generous policy than would otherwise be possible, and it may have the indirect effect of raising wages of the lowest grades.

As to the salary cuts of 1931, inflicted on members of military and civil forces, judges, doctors, and teachers, they have all of them given rise to irritation; some indeed may be said to have led to something like blood-poisoning. The fact that, among the sufferers, panel practitioners have complained comparatively little does not mean that they will by any means despise the half-cure wrought by the Chancellor's return of 5 per cent. of the insurance capitation fee. They will also benefit with other taxpayers by the 6*d.* reduction in the standard rate of income tax. Most members of the medical profession would probably have gained a good deal more by restoration of the old allowances permissible on small incomes, but the Chancellor regards the subtraction of 6*d.* from the standard as much more likely to stimulate trade. Apart from a somewhat surprising gift to the motor industry, this is indeed his chief contribution to industrial recovery; for he has decided to use the whole of last year's surplus—bought at no little cost—for repayment of the National Debt, and on the basis of this year's taxation he calculates that he will have only about £29,000,000 to devote to increase of expenditure or relief of the taxpayer. This cautious estimate explains why the Budget offers no provision for such projects as the raising of the school age, the distribution of milk to all school-children, or the encouragement of surveys and research—not to speak of large public undertakings or loans for reconstruction in the derelict areas. Mr. CHAMBERLAIN, conscious of heavy responsibilities, defers such expenditure until such time as it can be met from income, and meanwhile continues his example of economy; he holds, with show of reason, that the tonic effect of his surplus has been worth the privations that brought it into existence, and he evidently hopes to repeat the prescription next spring. In times of uncertainty such as the present, this point of view is incompatible with the use of the Budget as an instrument of national development, and those who are urgent for new plans for a new society will find little in its favour. It has, nevertheless, the merit of expectedness. The Government have been consistent in their anxiety to restore financial confidence and in their condemnation of financial experiments, and by giving full expression to this policy the present Budget provides something to please everybody. Supporters will find no fault with its evident soundness; the public will be thankful for its reliefs; and opponents will feel an inverted satisfaction, because it leaves them with nearly all their major criticisms of the Administration unimpaired.

SOVIET INSTITUTE OF EXPERIMENTAL MEDICINE.—A branch of the All-Union Institute of Experimental Medicine has been established in Moscow, its members including Profs. Rozenkov (director of the branch), P. P. Lazarev, Propper (assistant director), Krol, Levit, Konchalovsky, and Shaternikov. Its work will deal with human physiology and pathology, and special attention will be paid to the connexion between the higher nervous activities and the functions of sense organs. Laboratories for studying industrial physiology have been provided, and climatic stations have been opened in Yalta, Murmansk, Prozorovka (near Moscow), and Ashkabad.

a total of 5216 showed a loss of 8 to 18 units, and 0·75 per cent. a loss of 21 to 30 units, but that only three children of the total 2608 examined had a loss of 21 units or over in the better ear. It is obvious that the slighter degrees of deafness, and many cases of unilateral defect, would have escaped detection without some such method of wholesale examination; this is well shown by the fact that the returns for the routine medical inspection of school-children given in the annual reports of the chief medical officer of the Board of Education have, for some years past, recorded the incidence of defects of hearing as slightly less than 0·5 per cent.; indeed, the Board states that deterioration of hearing may go on for some time before it is detected. A reliable physiological method of assessing the hearing of school-children with reasonable speed is of the greatest value in detecting deafness at an early stage, so that appropriate treatment may be instituted; Dr. Crowden furnishes charts which demonstrate the improvement which has occurred after treatment. A modification of the gramophone audiometer has been made for the examination of children of pre-school age who are unable to write; this consists in a record of a series of words combined with pictures of objects which they represent.

THE ÆTIOLOGY OF AGRANULOCYTOSIS

CASES of agranulocytosis fall roughly into two groups—those secondary to sepsis or to administration of certain drugs, and those which are called primary or idiopathic because their cause is unknown. The number of chemical substances now recognised as capable of injuring the bone-marrow of susceptible persons is rapidly increasing. The injury may affect all the marrow components, giving the typical picture, during life, of an aplastic anæmia; or it may depress only one marrow element. Benzene derivatives usually produce a sharp fall of red cells, white cells, and platelets, but they may affect the granulocytes selectively; similarly, arsenobenzol derivatives may have a selective action upon these cells. Dameshek,[1] who has recently reviewed the hæmatological reactions recorded as following administration of gold salts such as Sanocrysin, shows that these have included complete aplastic anæmia, agranulocytosis, and thrombocytopenic purpura. It seems that the barbiturate group of drugs also—given alone or in combination with amidopyrin—may exert a selective toxic influence upon the marrow elements, more particularly the granulocytes. Watkins[2] reports that 24 out of 32 patients with primary agranulocytosis coming under his observation had taken one or both of these drugs before the onset of symptoms, while Madison and Squier[3] have described 14 cases in which the onset of symptoms was directly preceded by use of amidopyrin either alone or in combination with a barbiturate. When single doses of amidopyrin were given to each of two patients who recovered from the acute disease, their granulocytes were much reduced. In our present issue Dr. F. E. Loewy describes two cases of thrombopenic-hæmorrhagic purpura attributable to use of the hypnotic Sedormid (allylisopropyl-acetyl-urea) which is allied to the barbiturates. Both Loewy and Madison suggest that these effects are due to an allergic or "anaphylactoid" drug reaction. The widespread use of the remedies under discussion, compared with the rarity of agranulocytosis, indicates that, as with so many poisons, idiosyncrasy plays an important part in determining the character of the reaction.

Of cases commonly regarded as primary agranulocytosis, there are some at least in which yet other ætiological factors are concerned; for there is sometimes apparently a relationship between the neutropenic episodes and the hormones associated with menstruation. Over 80 per cent. of the recorded cases of agranulocytosis have been in women, and Thompson found that in 17 out of a group of 18 cases the subjective symptoms of agranulocytosis developed within one or two days of the onset of the regular menstrual period, and that all the patients were menstruating when admitted to hospital. In six of them there were one or more recurrences of neutropenia, always in association with menstruation. Jackson and Merrill have now reported in detail[4] the case of a woman who had had recurrent attacks of agranulocytic angina. She had herself noticed that relapses always took place on the first day of her menstrual period. Her peripheral blood picture was studied closely for ten months, and it was found that with the onset of each menstrual period the total number of neutrophil leucocytes fell precipitately, only to rise again rather rapidly to about the previous level. During this period there were two attacks of acute illness. Thompson[5] has also described the case of a man aged 25 who from the age of 2½ months has been known to have had a cyclic neutropenia. The cycles are identical, the attacks occurring at an interval of exactly three weeks. The fall in granulocytes definitely precedes the onset of fever and buccal necroses; it can be prevented by treatment with nucleotide K.96. If the granulocytes are maintained at normal levels by prophylactic therapy no subjective symptoms appear. As the patient also has diabetes insipidus and other signs suggestive of endocrine disturbance his hormone excretion has been studied, and it has been found that in his case definite variations in the excretion of female sex hormone and of gonadotropic hormone occur in association with a neutropenic period.

Without drawing further conclusions it is clear that in future the possible relationship of attacks of agranulocytosis to menstruation and to certain drugs—especially amidopyrin and the barbiturates—must always be borne in mind.

MORTALITY FROM APPENDICITIS

IN 75 leading American hospitals the number of cases treated for appendicitis has increased from about 18,000 in 1923 to over 26,000 in 1932, and of these nearly 94 per cent. underwent operation. Dr. Frederick Hoffman, who has collected[6] the figures, does not indicate whether there is a real increase in incidence or merely in resort to these hospitals, although he finds that the crude death-rate from appendicitis in 60 American cities (with an aggregate population of 29 millions) has risen from 133 per million in 1910 to 157 per million in 1932. A maximum of 180 per million was reached in 1929, since when there has been a decline. These figures have given rise to some anxiety, and in Philadelphia there has been inaugurated a campaign for the reduction in fatality of acute appendicitis by shortening the time between the onset of symptoms and recourse to hospitals and by preventing the administration of laxatives. A report of its progress is given [7] by Dr. John Bower. The case-fatality rate has, it appears, declined from 5·97 per cent. in 1928–29 to 3·44 in 1932, or by 42 per cent., a part of the improvement being due to earlier hospital treatment. The importance of this factor is suggested by the fact that during 1928 to 1932 only 2 per cent. died of those admitted within 24 hours of the onset of symptoms compared with nearly 10 per cent. of those whose admission was delayed till after 72 hours—though selection may play a part in this result for cases that become quiescent after 72 hours would tend not to be taken to hospital. There has also been some decline in the number of cases of peritonitis and the fatality experienced by them, and a less frequent administration of laxatives is reported. An influence, however, that may, it seems, have been largely responsible for the reduction in the fatality-rate is the considerable increase in the actual number of cases operated upon. In 1928–29 the average number of cases per annum was 2560; in 1930 the number rose to 3095; in 1931 to 3142; and in 1932 to 3546, an increase of nearly 40 per cent. in three to four years. Such figures suggest that there has been a considerable rise in the number of mild cases, which would favourably influence the fatality-rate—i.e., the ratio of deaths to cases. From such a sequence of events it appears that the active measures of such a campaign may reduce the number of deaths in the community but may at the same time increase considerably the "unnecessary" operations which Dr. Hoffman criticises. An increase in mortality, it may be noted, is not apparent in this country. In England and Wales as a whole there has been no appreciable variation in the death-rate from appendicitis over the last 20 years; the rate for males has fluctuated slightly around 80 per million, for females around 55 per million, with no tendency either to rise or fall.

NERVE-GRAFTING FOR FACIAL PALSY

A FILM illustrating the results of nerve-grafting for the relief of facial paralysis, as carried out by Dr. A. B. Duel of New York, was shown to the council of the Royal College of Surgeons of England on April 12th. The method adopted is the result of a series of experiments by Dr. Duel and Sir Charles Ballance. A small peripheral nerve is prepared by section in situ 10 to 21 days before the operation, and this nerve is implanted in the Fallopian canal without sutures and covered over with gold foil. Rapid recovery may take place even where the facial paralysis has existed for some time, but in cases of long standing the decision whether operation shall be undertaken must depend on whether the muscles of the face respond to the galvanic current. It is found that when prepared grafts are used the faradic response returns in the palsied muscles in less than half the time required when a fresh nerve-graft is employed. The degenerated nerve-graft consists of a series of tubes through which the axis-cylinders of the central nerve segment push their way.

Sir Charles Ballance left America 18 months ago and has not been able to continue in London the work he was doing with Dr. Duel. The latter, however, has gone on with the research on monkeys and has also, it was stated, treated with great success a large number of patients suffering from facial palsy. In cases of Bell's palsy he has operated on many cases, decompressing the inflamed and swollen nerve in the aqueduct by removing the outer bony boundary of the canal and slitting up the fibrous sheath. Anastomosis of the facial nerve with another nerve in the neck is definitely abandoned for the operation of exposing the nerve in the canal, excising the diseased or damaged portion, and placing a prepared graft in the gap so formed.

On the same occasion Mr. V. E. Negus showed a film illustrating ciliary activity and the action of various drugs on ciliary movement.

MEASLES SERUM

OUR advertisement columns contain the announcement that a limited supply of serum obtained from patients convalescent from measles is available at the London Fever Hospital and may be had by practitioners who wish to use it for the protection of infants and young children. It is now generally agreed that a single injection of such serum is usually sufficient to prevent or modify an attack of measles: if temporary protection is desired the injection should be given on or before the fifth day of incubation; if the object is to ensure a mild attack with subsequent immunity it should be deferred until the sixth to ninth day.[1] The principal obstacle to a more general use of this preventive is the difficulty of obtaining a sufficient supply, and the committee of the London Fever Hospital would be glad if patients who have recently had the disease would volunteer to attend and have blood taken. It is felt that practitioners may be able to bring this useful service to the notice of some of their patients who would like to play a part in safeguarding others.

REFUGEE SCIENTISTS

FOR over a year, through the work of the German Refugees Assistance Fund, a certain number of Germans of academic and professional standing have been enabled to continue their studies, and in some cases to find a paid outlet for their talents. But despite the efforts of a powerful body of supporters, the fact remains that the list of those who need similar assistance is sadly large. It is estimated that there are at least 60,000 refugees of this kind outside Germany, and most of these are dependent to some extent on charity or the kindness of friends, for any savings they were able to bring from their home land are exhausted by now. We are informed that there are 9000 medical doctors on the list of the International Committee for the Relief of Refugee Professional Workers, of whom a proportion—how many is unknown—are in this country. The financial call is very large, but no more worthy object for subscription can be found. The German Refugees Assistance Fund acknowledges that only if large sums are available for making settlements can the destitution really be reduced, but with the coöperation of such societies as the Academic Assistance Council, the International Student Service, the Germany Emergency Committee of the Society of Friends, the International Committee for Assisting Refugee Professional Workers, and the Save the Children Fund substantial support may be hoped for. Comparatively moderate subsidies at the present moment may, however, lead to members of the medical profession who are now in receipt of charity becoming not only self-supporting but able to help others, as witness the following typical cases: "A B, aged 50, married (two children), bacteriologist, dismissed after 21 years' service because grandparent was Jewish, engaged on work of extreme importance; £250 needed for maintenance for one year. C D (M.D.).

[1] THE LANCET, Feb. 3rd, 1934, p. 254; also 1932, ii., 572; 1933, ii., 981.

Was in charge of department in well-known Berlin hospital. Has to keep parents. Can enter into partnership in Italy as soon as he has British qualification. Requires assistance towards paying examination fees, £45. E F (a lawyer) can be re-trained for agriculture in Denmark, and then has chance of going to Palestine, £40. Expenses required for several doctors taking up positions in Turkish hospitals, £120 each." The quotations are from the German Refugees Assistance Fund, and we bring the plea of that Fund before our readers with full knowledge that they have urgent claims upon them already furnished by the needs of our own charities. But their help can be great if they will give publicity to the work of the Fund, and lead the public to realise that the progress of all that makes the world habitable is linked up with the labours of the academic and professional classes. There is no question of the employment of more foreign medical practitioners in Britain, and this is recognised by the Fund.

THE VIRUS OF MUMPS

QUITE apart from the results of attempts to reproduce mumps experimentally there are grounds for believing that it belongs to the group of filtrable virus diseases. It is highly contagious, one attack confers a solid and lasting immunity, and when it has been possible to examine the specific lesion histologically the inflammatory reaction has been seen to be predominantly mononuclear. Experimental investigation of the disease dates from 1908 when Granata published some suggestive findings. M. H. Gordon's[1] work several years later was more conclusive. He demonstrated the presence of a filtrable agent in the mouth washings from early cases of mumps, but in only one instance did he show that this agent was capable of producing a parotitis in experimental animals and serial passage was not achieved. Martha Wollstein[2] carried the matter further. Investigations pursued by her between the years 1916 and 1921 showed that the filtered mouth washings from early cases produced an inflammatory reaction when inoculated into the parotid or testis of the cat and that serial passage was possible, though not indefinitely so, in this animal species. She also found that the virus was present in the blood of patients with severe constitutional symptoms. The ensuing decade saw two further attacks on the problem. Y. Kermorgant's[3] work claiming to show that mumps was due to the combined action of a spirochæte and a Gram-negative bacillus remains unconfirmed and unconvincing, and F. F. Tang's[4] findings in guinea-pigs give the impression that if he was dealing with a filtrable virus it was not the virus of mumps.

Recent work by C. D. Johnson and E. W. Goodpasture[5] leaves little doubt that mumps is in fact produced by a filtrable virus. Their experiments were made on monkeys (*Macacus rhesus*) and the material investigated (fresh saliva) was introduced directly into Stensen's duct in quantities of 2 c.cm. Saliva from six early cases was thus inoculated into six macaque monkeys; two monkeys received a similar inoculation of normal saliva and served as controls. The introduction of this volume of fluid caused an immediate enlargement of the parotid gland which, however, subsided in two to four days. Nothing further happened in the two control monkeys and in two of the six receiving mumps saliva. But six to eight days later the remaining four monkeys developed fever, accompanied by swelling of the parotid gland and œdema of the surrounding tissue. They also showed definite changes in their blood picture: a leucocytosis, appearing just before the onset of pyrexia, was gradually replaced by a leucopenia with a monocytosis and a relative lymphocytosis. Histological examination showed that these glands were the seat of focal degeneration and necrosis affecting single acini or groups of acini. Suspensions of the extirpated parotid glands when passed through Berkefeld filters reproduced the disease in monkeys and serial passage was realised up to the seventh generation. Monkeys which had recovered from the infection proved resistant to reinoculation, but neutralisation experiments with human convalescent sera gave inconclusive results. When it is added that Johnson and Goodpasture also demonstrated the resistance of this filtrable agent to freezing, drying, and glycerol, it will be realised how complete is the story which they present.

SUMMER Time will commence in Great Britain, Ireland, the Channel Islands, and the Isle of Man on Sunday morning next, April 22nd, at 2 A.M., when the hands of timepieces should be advanced one hour. It will end on Sunday, Oct. 7th.

"INDIA," by Lieut.-Colonel F. D. S. Fayrer, I.M.S. (rtd.), M.A. Cantab., F.R.P.S., is the title of an exhibition at the Galleries of the Royal Photographic Society of Great Britain, 35, Russell-square, W.C.1, which will be held from May 3rd to 31st, 1934.

FOR reasons of health Mr. F. W. Ramsay has resigned his prospective presidency of the British Medical Association during the coming year. In his place Dr. Sydney Watson Smith, physician to the Royal Victoria and West Hants Hospital, has been appointed president for 1934–35, and he will take office at the annual meeting of the Association to be held in Bournemouth next July.

A SPECIAL meeting of the Fellows of the Royal Society of Medicine will be held on Tuesday, May 1st, at 8 P.M., when a demonstration will be given by Dr. Russell Reynolds on X ray cinematography. Some interesting films will at the same time be shown by Dr. Robert Janker of Bonn. The meeting has been devised in order to bring Dr. Janker into contact with Dr. Reynolds, as both have been working with a view to bring cinematograph technique within the bounds of application for use with X rays. Dr. Brailsford dealt with some aspects of this application in an address summarised on p. 877 of our present issue. It should be noticed by Fellows that admission can be by ticket only, and applications for these should be addressed to the secretary of the society at 1, Wimpole-street, W.1.

COURSE ON MENTAL WELFARE.—The Central Association for Mental Welfare have arranged a course for officers of local authorities and local associations for mental welfare engaged in work among the mentally defective. It will be held in London from June 30th to July 21st and will include lectures and practical work. Applications should reach the secretary of the association, 24, Buckingham Palace-road, London, S.W.1, before June 11th.

PROGNOSIS

A Series of Signed Articles contributed by invitation

III.—TUBERCULOUS LARYNGITIS

THE improvement in the prospect of recovery from tuberculosis of the larynx may be well exemplified by quoting Sir Morell Mackenzie, who wrote in 1880 that "the prognosis is always extremely grave, and it is not certain that any cases recover." The second statement in this quotation is certainly no longer true, for a considerable proportion of patients do now recover. This is in part due to a more general early recognition of the disease, for the laryngologists' plea for the routine laryngoscopic examination of all consumptives has been more widely accepted, and in part to the better management of the laryngeal disease by vocal rest and the judicious application of local treatment; but it is chiefly to be attributed to the gradual advance in the treatment of phthisis, and especially to the adoption of such methods as artificial pneumothorax and phrenic evulsion. To-day the advantages of sanatorium treatment have been brought within the reach of a far wider circle of consumptive patients, and accommodation for those in the poorer ranks of life has gradually been made more commensurate with their needs.

FAVOURABLE AND UNFAVOURABLE SIGNS AND SYMPTOMS

Laryngeal tuberculosis is but a complication of pulmonary phthisis, and the prognosis therefore depends primarily on the extent, virulence, and progress of the pulmonary disease, and secondarily on the situation and extent of the laryngeal lesions; that is to say, if the lesions in the lungs are in a curable stage, cure of the larynx is nearly always possible, and is probable if the laryngeal affection is not far advanced. On the other hand, if the pulmonary disease is not curable, the patient will sooner or later die of consumption, even though the laryngeal lesion becomes healed; and in such cases reinfection of the larynx is liable to occur. The condition of the larynx can, and not infrequently does, improve while the disease in the lungs is progressing, but the lungs never get better while the laryngeal disease is advancing. The progress of the general disease, and the resistance of the patient, can only be estimated after some weeks of observation under the most favourable conditions attainable, preferably in a sanatorium, with a careful record of the weight, temperature, pulse, and appetite. The temperament of the patient is also of importance; the *spes phthisica*, so often encountered, is a valuable aid to recovery, but may induce the patient to be careless and intolerant of the details of the régime prescribed; his active coöperation is necessary, and it has been well said that no fool is cured of the disease. Unfavourable symptoms are persistent elevation of temperature in spite of rest, rapid pulse, lack of appetite, loss of weight, and a bad family history. Pregnancy has a particularly bad effect on tuberculous laryngitis, and early induction of abortion has even been advocated.

In mixed syphilitic and tuberculous disease of the larynx the prognosis is bad. Age has an influence on the prognosis, older patients withstanding the disease better than younger ones; tuberculosis is seldom rapidly progressive in persons over 40 years of age. Biological tests may be of service in the estimation of the patient's resistance; Dr. F. R. G. Heaf[1] attaches importance to the information derived from serial examinations of the blood, and finds a rapid sedimentation-rate, with a high monocyte and low lymphocyte and eosinophil counts, of serious import.

THE SITE OF THE LESION

With regard to the site of the laryngeal disease, the most favourable is superficial infiltration or ulceration of the vocal cords, and with similar lesions or papillary outgrowths in the posterior commissure the prognosis is also fairly good. Infiltration at the upper aperture is far more serious than disease within the larynx; partly because it is of greater mass and extent, partly because it usually occurs when the interior of the larynx is already involved, but chiefly because it so often causes dysphagia. This is especially true of disease of the epiglottis, which is of the worst prognostic import; an exception to this is the rare case in which the epiglottis is the only part affected; I have seen two such cases, in both of which removal of the epiglottis resulted in cure. Another exception is the "lupoid" type of tuberculous laryngitis. This is relatively rare, and is associated with chronic pulmonary disease; it attacks the upper aperture early, is painless, and is characterised by slow progress and a tendency to heal with considerable formation of fibrous tissue. Of 255 cases at Mount Vernon Hospital, the proportion of deaths was 1 in 6½ where the epiglottis was involved, 1 in 9¼ in disease of the arytenoids, and 1 in 35 when the cords alone were affected. Perichondritis is of very sinister import, but there is one exception to this, namely, when tuberculosis attacks the thyroid cartilage as a primary disease; in such cases, if the swelling points externally, the outlook is good, especially if, as sometimes happens, there is no pulmonary disease. Miliary tubercles in the larynx are a terminal affection and indicate a rapid dissolution, and so too does the spread of ulceration to the fauces.

THE STAGE OF THE GENERAL DISEASE

In general, the more extensive the tuberculous infiltration the worse is the prognosis; but the mere fact that the larynx has become invaded is a sign of the patient's lowered resistance and lessens the prospect of recovery. Sir StClair Thomson,[2] in following up cases of phthisis, found that the presence of laryngeal tuberculosis doubled the mortality; over an equal term of years, of patients with an intact larynx two out of three will be alive, but only one out of three of those with a laryngeal lesion. He reported in 1914[3] at the King Edward VII Sanatorium arrest of the local disease in 20·7 per cent., and more recently in 1924[4] in 25 per cent.; I recorded at the Mount Vernon Hospital in 1905[5] a proportion of 20·85 per cent. in a series of cases which excluded those admitted in a very advanced stage, chiefly for the relief of dysphagia. But it must be remembered that these figures were compiled before the treatment of tuberculosis in general had progressed as far as it has at present, and moreover that statistics of the cure of laryngeal tuberculosis can never be of more than approximate value, since results depend greatly on the class of patient and on the stage of disease at which these come under treatment. Thus a series of cases seen in private practice, or in sanatorium, where the diagnosis is made in an early stage, will show better results than those treated at a throat clinic, where the patients seldom present themselves until symptoms of trouble in the throat have already become obvious.

CONCLUSION

The larynx is far more prone to invasion when the pulmonary disease is advanced than when it is in an early stage. Here again statistics differ greatly: in group I cases of phthisis laryngeal tuberculosis has been found in from 4·50 to 13·75 per cent., among group III cases in between 31 and 72 per cent., and post mortem in from 48 to 83 per cent. The percentage of cases of arrested laryngeal disease is, of course, materially diminished by the large proportion which occurs in a late stage of consumption, where there is no prospect of recovery; in these it is not the disease in the larynx which causes death. But, where the pulmonary disease is still in a curable stage, I would repeat that cure of the larynx is nearly always possible, and we may expect that the percentage of cures will increase as early diagnosis becomes still more frequent and facilities for modern treatment are extended.

MEDICINE AND THE LAW

Blood Test Offer in Affiliation Proceedings

APPEARING last week before the Chatham magistrates on behalf of the mother in affiliation proceedings, an advocate expressed the opinion that, sooner or later, blood tests would be regarded as a necessity in these and other cases. He offered to have the blood of the mother and her child tested, provided that the putative father would also submit to the same test. He also undertook to pay the costs of the medical research involved in the classification and comparison of the blood specimens. The offer was not accepted, and the magistrates seem to have treated it rather as a forensic flourish than as a serious contribution to the evidence; they had, of course, no power to compel the parties to undergo blood tests.

The case was a remarkable one. In 1931 Miss Sophie Batchelor obtained an affiliation order against Mr. John Smith for payment of 10*s*. a week. Mr. Smith strenuously denied paternity; he refused to obey the order and was committed to prison no fewer than 19 times in default of payment. Last February Miss Batchelor was charged with perjury in connexion with the affiliation proceedings of 1931; she was found guilty at Maidstone assizes before Mr. Justice Roche and was sentenced to six weeks' imprisonment. The judge on that occasion expressed the opinion that Miss Batchelor had got her order by fraud and that the order ought not to be further enforced. The original finding of the magistrates against Mr. Smith, however, still stood in spite of the verdict of perjury against Miss Batchelor. Nothing less than an Act of Parliament could undo the magisterial decision that Mr. Smith was the father of Miss Batchelor's child, but Mr. Smith could at least apply to have that part of the order varied which compelled him to pay 10*s*. a week. When Mr. Smith gave evidence for this purpose last week he was asked in cross-examination if he would undergo a blood test. He answered that, if it was legal and if it would alter his obligation, he would undergo any test. The magistrates, without waiting for tests, found themselves able to revoke their order for the payment of 10*s*., inasmuch as it had been made on the faith of Miss Batchelor's evidence, which had now been found to be false. It has since been reported that the magistrates are being asked to state a case on Miss Batchelor's behalf for decision by the Divisional Court. An undertaking was given at the Maidstone assizes that she would take no further proceedings against Mr. Smith; evidently this was not interpreted as barring her from defending herself against Mr. Smith's attack on the order.

If his remarks were correctly reported, Miss Batchelor's legal representative last week seems to have put the evidential value of blood tests surprisingly high. He said he was informed that, out of 20,000 cases where blood tests had been made, it had been possible to establish definitely in 15,000 the existence of a certain blood relationship and to negative it in 5000. His opponent replied that he understood the blood of human beings could be placed in three groups. If the child's blood was found to belong to "A" group and the putative father's to belong to "B" group, it might be possible to say definitely that the man was not the father of the child. If the blood of both belonged to the same group, it would prove nothing. "My own blood might belong to the same group; could it be said in these circumstances that I am the father of the child?"

IRELAND

(FROM OUR OWN CORRESPONDENT)

CONDITIONS IN THE ARMY MEDICAL SERVICE OF THE IRISH FREE STATE

LAST week Mr. F. Aiken, the Minister for Defence, received a deputation appointed by the Irish Medical Committee and introduced by Dr. P. O'Dowd, T.D. The members were Dr. R. J. Rowlette, T.D., Dr. J. P. Shanley, and Dr. P. MacCarvill. It was pointed out to the Minister that the conditions concerning pensions for medical officers were not satisfactory. The pension given to a medical officer represented a much lower proportion to his salary than was the case with an officer in other branches of the Army. There was no reason for such discrimination against the medical service. Again, the rank of the head of the medical service was that of major, a rank lower than that held by the heads of the other branches. When the National Army was established the first medical head held the rank of major-general; on his retirement his successor was given the rank of colonel; since then the rank had been that of major. The deputation suggested too that the head of the medical service should be a member of the Army Council, in view of the fact that the work for which he was responsible was of primary importance, and was so highly technical that it could not be properly represented by a non-medical officer. The deputation impressed on the Minister that they had no wish to embarrass him, but they believed that he would be helped by occasional consultation with representatives of the medical profession. He promised to study the points that had been put before him.

CORRESPONDENCE

SAFE MILK

To the Editor of THE LANCET

SIR,—May I, as a milk-producer, comment on the memorandum on the milk-supply which appeared in your issue of April 7th over the signatures of a number of distinguished professional men? Anyone with inside knowledge of the milk industry must, unless he is blinded by prejudice and a hopeless reactionary, agree whole-heartedly with most of its conclusions and recommendations, but the condemnation of Certified and Grade A (Tuberculin-Tested) milk is somewhat disheartening to those who, like myself, have devoted much thought and hard work in the endeavour to produce a "safe" milk. For years we have been lectured about tuberculosis and the menace to human beings from bovine sources, and urged to free our herds from tuberculosis; and now, having done that, we are told that our milk is still not safe. I am not seeking to excuse the producer of dirty milk, but I ask—is there any foodstuff which can be regarded as absolutely fool-proof and safe? Occasional cases of milk-borne disease there have always been; but I seem to remember outbreaks of poisoning from meat pies, and even water has not altogether a clean record. Five hundred cases per annum of undulant fever, a disease of recent discovery and not very serious I believe, seem insignificant in proportion to the millions of gallons of milk consumed in the same period. Whatever one eats or drinks, one must take some risk. I cannot remember any doctors jibbing at the oysters on occasions when I have been privileged to dine in their company, though I certainly knew one who always cut all the crust off his bread and had his strawberries washed in a weak solution of permanganate of potash. One wonders whether doctors are not going a little too far with their hair-raising stories about milk. However, be that as it may, I am not one of the reactionary farmers who would argue the point and say that milk production to-day is perfect, and I am not qualified to discuss the merits of pasteurisation from the medical point of view. I want to work with the doctors all the time and do whatever I can to fall in with their views, if they on their part will help those of us who are trying to improve the milk-supply, and give us some guarantee they will not change their minds too soon.

As things are at present, the producers of Certified milk cannot pasteurise—the Minister of Health will not let us—but if the doctors can persuade the Minister to alter the regulations, I, for one, will certainly pasteurise for those who want it. There is no mention in the memorandum of palatability or vitamins. Many milk drinkers dislike the peculiar flavour imparted by pasteurisation, and I think that they might be allowed, after due warning of the awful fate in store for them, to take the risk of drinking their milk raw, provided the milk is of T.T. *origin* and produced under satisfactory conditions of cleanliness. And—are vitamins out of fashion? One knows that fashions change, in medicine presumably as in other spheres. It does not seem long since the doctors were stressing the importance of vitamins; but now, apparently, their importance is quite secondary.

But if we farmers are to coöperate with the doctors, it is only fair to ask that there should be some measure of agreement in the profession, and also that some steps should be taken to impress on doctors the desirability of acquiring some knowledge of milk production and distribution and the various regulations affecting the same. In my own experience of producing and selling the highest grade of milk I have come in contact with many doctors. From some I have had unstinted praise for my efforts, some have helped by recommending my milk to their patients, and some have even gone so far as to buy it for use in their own households. Still more have recommended it to their patients but have not taken it themselves, and I could fill more space than you, Sir, are likely to allow me with a recital of their various reasons for not doing so—especially the married ones. The majority do not seem to be interested at all, and display an ignorance of the whole question which is appalling in persons having their responsibilities. I venture to say that 75 per cent. of general practitioners do not know anything at all about either the Milk and Dairies Order or the Milk (Special Designations) Order, and 50 per cent. are still under the impression that Grade A milk is the highest obtainable grade.

It is a matter of regret that the memorandum deals almost entirely with milk production, and the question of contamination in distribution is ignored. In particular, one seeks for a condemnation of the out-of-date and filthy system of distribution by means of the open pail—even some of the doctors still have their milk ladled out on the back doorstep next to the ash-bin, the operation, in all probability, being performed by an unhygienic youth smoking a cigarette, and whose use of the pocket handkerchief is neither as frequent nor as thorough as the fastidious might consider desirable. But the poor farmer gets the blame for the septic sore-throat every time, and some of us who are really trying are apt to get a bit disheartened.—I am, Sir, yours faithfully,

Woolow, Buxton, April 14th. HAROLD C. LINGS.

THE PREVENTION OF CANCER

To the Editor of THE LANCET

SIR,—Dr. Cramer's paper in your issue of Jan. 6th marks a new start for the campaign against cancer. It embodies features which are essential for further progress towards control of this disease in man. The first of these is the shifting of the centre of cancer research from the laboratory and animal house to the community of man all over the world. I am not at all ungrateful to animal cancer experimenters; indeed, I believe they have established many important facts. But animal experiments with practical results applicable to cancer in man are few and far between.

A second promising feature of Dr. Cramer's paper is that he is trying to draw practical inferences from what is known about cancer in man. There are many observations, I believe, whose potential significance has not yet been fully explored; for example, the fact that a single cancer appears in a wide precancerous lesion; the fact that multiple primary cancers may originate simultaneously; and the genetic relation between the cells of the primary cancer and their host as emphasised by E. F. Bashford in 1911.

Dr. Cramer says that "a diminished frequency would indicate that the development of cancer in one site increases the resistance to the development of cancer in other sites, and thus protects against a subsequent carcinogenesis in other tissues and organs. Such a result would suggest obvious possibilities." Dr. J. A. Murray, in 1923, hinted at the same thing when he spoke of "a systemic constitutional change in the organism in which cancer has developed, a change which, if it could be recognised with certainty and rapidity, would enable us to recognise cancer in its earliest stages, and could we produce it without initiating new growth, would place in our hands a rational means of prevention" (Imper. Cancer Research Fund, 8th Scient. Rep.). Again, Sampson Handley in his book the "Genesis of Cancer" (1931) says: "It would seem that the explosion of one carcinoma nearly always inhibits the development of others by some biochemical process of which we are in ignorance.' And later he adds: "From the observation of Dukes that intestinal polypi tend to disappear after the appearance of a carcinoma, it would seem that this inhibitory power of a carcinoma is exerted also over papillomata." My own observations on the bilharzial cancer of the bladder, which is the commonest form of cancer met with in our post-mortem material, are in line with these statements. Although the bladder may present many bilharzial lesions, the cancerous process starts in one place only, and never in such bladders have I seen elevated papillomata associated with a declared carcinoma.

Analysing these facts, and inspired by Murray's writings, I argued that in order to prevent cancer it may be necessary to induce in the somatic epithelial cells of the normal person a biological state similar to that which is forced on them by the presence of a primary cancer. One way of doing this would be by artificially producing an anatomical association resembling that which obtains between a host and his primary cancer. This might be achieved by subcutaneously inoculating the normal person with living human cells which bear to him a relation similar to that which the cells of the primary cancer bear to their host. A source of such living human cells, I suggest, would be the fresh umbilical cord of a new-born child of the person in question, the covering of the umbilical cord being epithelium which is continuous at the umbilicus with that of the skin of the fœtus. Later the blood-cells of the offspring, injected into the parent, might suffice to maintain the desired inhibition.

The idea is that by inoculating a normal person with a living new generation of epithelial cells genetically related to him, we may imitate the biological state produced in man by the presence of a primary cancer in his body, and thereby protect him against subsequent carcinogenesis. In other words, we may thus succeed in diminishing the "intrinsic factor." It is obvious, however, that a very strong stimulus would always overcome an induced inhibition of this kind, and to any who may be inclined to test the effect of inoculating animals with living epithelial cells from their offspring I would like to suggest that the method should be tried as a means of preventing spontaneous cancer in normal animals and in strains of animals of various degrees of susceptibility and not as a protection against the initiation of cancer by highly potent carcinogenic agents. Such agents luckily are not in operation in human cancer of man, and in biological experiments we should imitate natural circumstances so far as we can.

The idea of preventive inoculation with a new generation of related living cells may, if accepted, open up a new field of experiment bearing more closely on human cancer than the work which has been done on resistance to transplanted tumours. Though very interesting, the results of such transplantation are obviously not applicable to man. The fact that resistance to transplantable tumours can be induced by inoculating an animal with normal tissues, such as living embryonic skin or living blood-cells or living placenta cells or living spleen cells of the same species, shows that tumour tissue when it produces a similar resistance acts in its capacity as a tissue and not as a mysterious thing called cancer. Again, the experiments done with autologous and homologous transplants have established the specific biological individuality of each organism, each one differing even from others of its own species. Cancer in man therefore should be considered not only as species-specific but also as individually specific—perhaps more so than in animals in which random mating obtains. The living cells of the progeny are, mathematically speaking, only half genetically related to their father and mother, but they are the only living new generation of genetically related cells that we can possibly lay hands on for a normal individual.

Thirdly, Dr. Cramer bids us no longer pay too much attention to what he calls "the nature of the intimate cellular change which transforms the normal cell into a malignant one." "Even if we did possess a knowledge of this change," he says, "it by no means follows that this would enable us to identify the external conditions which bring it about." This advice, I believe, is well founded—especially since we already know the following facts:—

(1) Cancer in man originates from an epithelial tissue that has been responding by proliferation to a stimulating irritation for a time long enough to be an appreciable fraction of a lifetime.

(2) Such long-standing irritation is always accompanied by important changes in the subepithelial connective tissue, and these are such that they interfere with the nutrition, oxygenation, and drainage of the superjacent epithelium.

(3) Whether or not the cells of this epithelium are directly injured by irritation, their circumstances are those most likely to bring on exhaustion and senescence.

(4) Senescence *in a living community of cells is* the signal for the formation of rejuvenated cells.

(5) Under normal conditions rejuvenated cells are made by an exchange of nuclear material between two senescent cells. No senescent cell can be rejuvenated from its own resources so long as it remains in the medium which brought about its senescence.

(6) Rejuvenation in nature is accomplished, in most of the well-studied forms of life, either by conjugation or fertilisation.

As I have suggested in a previous letter (THE LANCET, 1932, ii., 421) I believe we are justified in thinking that such a process of rejuvenation is responsible for the formation of "the cell" which *forms the germ of a primary cancer.* This origin would explain the phenomena both of spontaneous and experimental cancer in man and animals; and it provides the genetic relation between the individual and his primary cancer. I urge that we may, for the moment, rest content with this theory of the origin of the primary cancer, based, as it is, on strong analogy.

The chromosome complex of the somatic epithelial cells is identical with that of the primordial cells of the gonads; even the sex chromosomes are present, as was shown by H. M. Evans and O. Swezy in 1929. The somatic epithelial cells are living units, and if a community of them become depressed and senescent, rejuvenation should take place as it does in other living communities. Nature does not double her methods.—I am, Sir, yours faithfully,

M. F. SOROUR,
Medical Faculty, Cairo. Assistant Professor of Pathology.

GALL-STONES AND CARDIAC PAIN

To the Editor of THE LANCET

SIR,—Perhaps it is less unpermissible in medicine than in any other subject to inflict upon others one's personal experiences. The leading article in THE LANCET of April 14th on gall-stones and cardiac pain will perhaps be considered a sufficient excuse for this letter.

When a student at St. Mary's Hospital aged 23 years I had the honour of being reported in THE LANCET as a remarkable example of recovery from a very severe acute ulcerative colitis, owing my life to the skill of Sir William Broadbent, Dr. Sidney Phillips, and Dr. H. A. Caley, and to splendid nursing. This I mention because I believe this illness to have been probably the original cause for a subsequent cholecystectomy in 1931 for impaction of gall-stones in the cystic duct. This latter condition was a very puzzling one, without any violent pain, vomiting, or, as is frequently the case, jaundice. Eventually when examining at Glasgow I found a tumour which overnight felt like a growth in the bowel. The next morning it had quite disappeared, and having no desire to have fragments of my bowel excised I concentrated my mind upon the candidates. When later I asked kindly colleagues to find the tumour it had always disappeared, and certain other symptoms made the diagnosis vacillate between hysteria and coronary thrombosis. The tumour at last decided to stay long enough for Dr. C. Bolton and Mr. Gwynne Williams to confirm my diagnosis of its erratic existence, and at my request Mr. Williams cut it out with complete success. It was a strange-looking gall-bladder, I was told, with two impacted stones in the cystic duct.

For years at intervals I had had some rather horrible attacks, and later they could be divided into two types. The first consisted in waking at night with a strange feeling of what I would call an "internal sinister silence" allied to the feeling that you would expect when, having heard a stealthy step in the dark, you waited expecting to feel a dagger stuck into your heart. Then began a boring pain in the back and a steady progressive sensation of distension which in bad attacks made one feel one would burst. The pain was not acute but the general discomfort very great. The other type was of the anginal variety so well described by E. Doumer and quoted in your leading article. There occurred a sudden intense sense of impending dissolution. It was not painful, and only once or twice did a start of pain or numbness run down to the left elbow. I had many attacks and they were most interesting, when they were over, because they came on quite unexpectedly. One, for example, occurred when I was alone in my laboratory and had just picked up my hat to leave. I exclaimed involuntarily "It's all up," and yet ten minutes later walked down the stairs quite comfortably. The other was more embarrassing and occurred while I was examining in pathology for the M.R.C.P. A candidate had just commenced examining a specimen and fortunately the Bedell of the College had come into the room. The attack was gradual and gave me time to reach him, and I said "fetch me a wineglass of neat brandy." He did, and I drank it down and am not aware that I showed more ignorance of pathology after the attack than I had before. I got to learn thoroughly what a wonderful description that is "a sense of impending dissolution."

Nearly three years have passed since the cholecystectomy and I have never had another attack of this kind. Exertion never brought them on and I can still play a minus 20 grade game of tennis or golf; even when they were occurring I could play a game of cricket without the slightest threatening of an attack. Should any of my friends the cardiologists happen to slip off the heart on to the gall-bladder I can hear them say, "What about your T wave?" I confess I object to my T wave being questioned. If it is depressed then I might be depressed, and I much prefer my memories of the alcoholic wave to any memory of my T wave. What I can say now is that I do not live upon neat brandy, though no remedy equalled it for those attacks. I have been able without disaster to do the duties of a physician to two hospitals for two and a half years since the operation, to continue examining and disturbing the peace of others with written articles on various subjects. I can also say that up to this moment the attacks have ceased and, if anything, I can take stairs better than four years ago, and increasingly better.

As far as direct personal observation is of value I am convinced that there was a mysterious relation between the condition of the gall-bladder with its vagal and sympathetic innervation and the anginal type of my symptoms, because since Mr. Gwynne Williams cut off the poor relation these strange attacks have ceased, and I have done nothing to prevent their recurrence except to decide that without a gall-bladder it is well not to eat hot fat or a large dinner. I am, Sir, yours faithfully,

Harley-street, W., April 16th. F. JOHN POYNTON.

MALNUTRITION

To the Editor of THE LANCET

SIR,—At a recent meeting in London several members of the medical profession found themselves in general agreement on the following points:—

1. That there exists in this country widespread under-nourishment among the families of unemployed and low-paid workers.
2. That this must inevitably lead to a steady deterioration in the physical standards and health of the population; and of this deterioration there are already signs.
3. The last thing upon which a community must economise is the nutrition of its working class.

We are perfectly aware that the nutritional standards of the working class can only be maintained and improved by an increase, often a considerable increase, in the scale of wages and relief, and by an extension of such services as school feeding and the provision of milk and meals at clinics, &c. Demands of this kind are constantly made by organised labour; and these demands frequently resolve themselves, in our opinion, into a claim for sufficient and proper nourishment. It is not our business collectively to initiate such demands and campaigns. But we do consider it our business to give the widest publicity to the facts as we know them, and to place our material at the disposal of any individual or organisation that wishes honestly to combat malnutrition.

A committee has been established, to be called the Committee Against Malnutrition. Its aim is solely that of giving numbers of persons throughout the country the opportunity of centralising their information and coördinating all efforts to one end—the securing of adequate nourishment for every man, woman, and child. We invite all members of the medical profession, scientific and social workers, who agree generally with our three premises, to become associates of the committee. Subscriptions are fixed at 5s. a year (to entitle associates to the bi-monthly bulletin of the committee), such subscriptions covering no more than postage and the purchase of reports, journals, &c., necessary for the committee's work. The committee is undertaking the following work; and associates, where they themselves desire it, are invited to participate.

(1) Publication of bi-monthly bulletin of extracts from the recent reports, publications, &c., sociological and political notes on public nutrition. To this bulletin associates are invited to contribute. (2) Articles and letters to the press, national and provincial, on the subject of malnutrition. (3) Publication of pamphlets and books and assistance to all suitable organisations desirous of issuing such pamphlets. (4) Lectures to such organisations as teachers' groups, religious bodies, coöperative guilds, trade-union branches, and so forth, and the supply of notes to any who wish to lecture. (5) Suitable support to any direct campaigns for increase of food standards—e.g., for free school feeding for families of unemployed workers, provision of free milk at clinics, meals at nursery schools, scales of relief adequate to supply full nourishment, and so forth.

It is not intended to publish any list of associates, but the committee will always be pleased to put associates into touch with one another and with interested organisations. Those who wish to apply for associateship, or who desire further information, are invited to write to the bureau secretary, F. Le Gros Clark, 19c, Eagle-street, Holborn, London, W.C. 1. On behalf of the committee,

We are, Sir, yours faithfully,

HELEN M. JARDINE, M.B., M.M.S.A.
AUDREY E. RUSSELL, M.B.
FRANCIS LOUIS, F.R.C.S.
SAMUEL LEFF, M.B.
F. LE GROS CLARK, B.A.

THE BLOOD-BRAIN BARRIER IN INFECTIOUS DISEASES

To the Editor of THE LANCET

SIR,—In the valuable paper on this subject by Dr. Friedemann and Dr. Elkeles, published in THE LANCET for April 7th and 14th, there occur two statements which cause me no little surprise. The first, which is repeated in different words more than once, is that "the current opinion [is] . . . that death in diphtheria is due to poisoning of brain centres" (p. 720). Now, whatever may have been the teaching in Berlin and other places abroad, I can safely state that such a view has not been held in the British Isles by any teacher whose clinical experience of diphtheria has been at all extensive. The changes that have been observed, and rarely observed, by microscopical examination of the brain in human diphtheria have been regarded by clinical observers as of little or no significance in respect of the symptoms and course of the disease. Cerebral symptoms are very rare in diphtheria.

The other statement is that "the pathological changes of the vascular system have *now* become the central problem in the pathogenesis of diphtheria" (p. 777; the italics are mine). Again, that may be so in Berlin and elsewhere. But the primary importance of these changes has been recognised in this country for many years. Fourteen years ago Dr. Esther Harding published her book, alluded to by Dr. Friedemann and Dr. Elkeles, "The Circulatory Failure in Diphtheria," a work in my opinion of the highest value, and the more so because the conclusions Dr. Harding arrived at were the result of careful clinical observation of the disease in the human being. Lastly, may I be permitted to say that several years ago I wrote as follows: "The most important of the effects produced by the toxin of diphtheria are those which are to be observed in the circulation" ("A Text Book of Infectious Diseases," 1928, p. 163). Following Dr. Biernacki, Dr. Harding and others, and as the outcome of my own experience, I pointed out that the circulatory changes were chiefly peripheral.

I am, Sir, yours faithfully,

Hampstead, April 14th. E. W. GOODALL.

To the Editor of THE LANCET

SIR,—It is very difficult to reconcile Drs. Friedemann and Elkeles' views on the permeability of blood-brain barrier to diphtheria toxin with Kramer's work on ultra-filtration (*Jour. Gen. Physiol.*, 1926, ix., 811). He showed that colloidal dyestuffs would only pass through a filter with the same charge. As all the present available evidence suggests that animal or vegetable membranes in neutral aqueous solution possess a negative charge, one would expect that, if the diphtheria toxin persists in the blood as a negatively charged colloid, it would pass through the capillary barrier, but Drs. Friedemann and Elkeles show that it does not. It has long been known that diphtheria toxin at the pH of the body fluid is an anion (Field and Teague, 1907), but what we do not know is what change the toxin undergoes in vivo after the characteristic incubation period. Some change must occur in the toxin in vivo to render it toxic. Drs. Friedemann and Elkeles' illustration of acid and basic dyes is not exactly comparable, as the negative anions of these acid dyes remain non-toxic and do not become toxic after an incubation period like diphtheria toxin. It is also known that diphtheria toxin rapidly disappears from the circulation and does not circulate unchanged for days as Germanin does. One would expect any colloid micelle or polyvalent metallic kation carrying a positive charge in vitro to be immediately toxic, owing to their powerful property of flocculating the negatively charged colloidal micelles of the organism in the blood or by their similar effects in destroying the capillary membrane, thus rendering them permeable to the toxin. The effect of the diphtheria toxin is more like that of some of the complex metallic compounds recently introduced into medicine (Allochrysine, Thiobismol, &c.) where the metal is a part of the complex anion. In these compounds the toxic heavy metal effects do not show themselves until after a long interval, presumably because of the ultimate decomposition of the complex anion with liberation of a positively charged metallic ion.

The writer has suggested that the ultimate effect of diphtheria toxin resembles that of a positively charged colloid (Med. Officer, Jan. 24th, 1931), owing to the resemblance of its effects to that of the absorption of polyvalent metallic kations (Pb, Hg, Au, Br, Sn, &c.)—namely, vomiting, albuminuria, circulatory failure, and late paralysis. The experimental evidence supporting this view was based on observations of certain colloid changes observed in the particles, probably lipoidal, rendered visible in the serum by dark-ground illumination. I showed that the injection of 20 per cent. of intravenous glucose (a reducing agent, or agent capable of donating electrons) and the administration of large doses of alkalis, which tend to alter the pH of the blood in an alkaline direction, and iodine, a foreign anion, had a beneficial effect in the prevention and treatment of the circulatory failure of diphtheria and the reduction of the percentage of severe late paralysis. If Drs. Friedemann and Elkeles' views are right, these agents should make the patient worse. Our methods have been used on 3200 cases of diphtheria with a death-rate of 2·9 per cent., although many hypertoxic cases are still occurring in Bristol. These results would seem to support our views.

I am, Sir, yours faithfully,
B. A. PETERS, M.D. Cantab.

Ham Green Hospital and Sanatorium, April 17th.

HUMAN BLOOD-SERUM FOR SEPTICÆMIA

To the Editor of THE LANCET

SIR,—In reference to the contribution by Dr. Lazarus-Barlow and Dr. Chamberlain on the value of human blood-serum in septicæmia, which appears in THE LANCET of March 10th, one is led to infer that the authors are not acquainted with the previous literature on the subject. In a paper entitled "Complement in Health and Disease" (Canad. Med. Assoc. Jour., April, 1926), the use of human blood-serum in septicæmia is described and experimental evidence submitted why it should be used in these cases. The subject was amplified in two further papers, "A Method of Serum Therapy for Septicæmia" (ibid., July, 1928), and "Some Immunological Problems in Septicæmia" (Brit. Med. Jour., Sept. 20th, 1930). References to the method described in these papers have appeared at intervals in THE LANCET and other journals, and in a thorough discussion of the special methods adopted in treating septicæmia (Jour. Lab. and Clin. Med., April, 1931) Dr. J. A. Kolmer reviews this specific method.

The favourable results noted by Dr. Lazarus-Barlow and Dr. Chamberlain are in agreement with the beneficial results noted in a more extensive series of cases and described in the above-mentioned papers.

I am, Sir, yours faithfully,

Winnipeg, March 29th. FRED T. CADHAM.

TOBACCO SMOKING AND DUODENAL ULCER

To the Editor of THE LANCET

SIR,—Referring to Dr. O. A. Trowell's inquiry (published in your last issue, p. 808) into the relation of tobacco smoking to the incidence of chronic duodenal ulcer, it appears that a factor of some consequence has been ignored. The smoker of cigarettes swallows tobacco dust with his saliva and an infusion of tobacco is brewed in his stomach. If he has taken food recently the poisons in the infusion are diluted and to some extent they are decomposed into simpler and less harmful compounds by the digestive juices. Cigarette smoking before breakfast is particularly hurtful because the infusion is concentrated and poisons the gastric mucosa to such an extent that there is some paralysis of the cells which secrete the digestive juices. There follows little digestion of the poisonous infusion and impaired digestion of the succeeding meal.

I should like to see the whole question reopened with full statistical honours and with special reference to the relation of cigarette smoking before breakfast to the incidence of chronic duodenal ulcer.

I am, Sir, yours faithfully,

London, S.W., April 15th. S. G. ASKEY.

*** We regret that in some copies of the issue two figures dropped out of Dr. Trowell's Table II. The standard deviation to the average 12·0 cigarettes per day should read ±0·82.—ED. L.

HYPNOTISM

To the Editor of THE LANCET

SIR,—In your notice of my last book, "Hypnotism—the Friend of Man," you stated that I have therein represented hypnotism as an "universal panacea." In the first article which I wrote (after nine years' investigation and experimentation) on hypnotism, I remarked: "To pretend to cure all, or nearly all, complaints by hypnotism is sheer quackery" (Weekly Times and Echo, Oct. 29th, 1911). In my book entitled "Rational Hypnotism" (published in 1914) I stressed the same fact; and in "Hypnotism—the Friend of Man" I wrote: "There are some cases wherein hypnotism, even if backed by the most skilful of other treatment, is powerless, or only of use for the alleviation of coincident and aggravating troubles." What I claimed especially with regard to hypnotism is that, in view of the mental factor in complaints, "there are extremely few cases of disease or disability in which the employment of hypnotism is counter-indicated." And therein I had the support of various leading qualified practitioners.

I am, Sir, yours faithfully,
J. LOUIS ORTON.

Hawthorn Drive, Uxbridge, April 12th.

*** Mr. Orton's quotation gives the clue to our reviewer's remark.—ED. L.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

THE following appointment has been made: Surg. Comdr. N. A. H. Barlow to *Victory*, for R.N.B.

ROYAL NAVAL VOLUNTEER RESERVE

Proby. Surg. Lt. P. C. Lewis to be Surg. Lt.
Surg. Sub-Lt. G. F. Jones to be Surg. Lt.

ARMY MEDICAL SERVICE

Col. C. D. Myles, late R.A.M.C., retires on retd. pay.
Lt.-Col. & Bt. Col. G. S. Wallace, from R.A.M.C., to be Col.

ROYAL ARMY MEDICAL CORPS

Maj. R. C. Paris to be Lt.-Col.
Maj. & Bt. Lt.-Col. O. W. McSheehy to be Lt.-Col.

TERRITORIAL ARMY

Capt. J. K. Rennie resigns his commn. and retains his rank, with permission to wear the prescribed uniform.

ROYAL AIR FORCE

Flight Lt. T. V. O'Brien is promoted to the rank of Squadron Leader.

Flying Offr. W. Hall is promoted to the rank of Flight Lt.

Dental Branch.—Flying Offr. V. H. Weeks is promoted to the rank of Flight Lt.

CHARING CROSS HOSPITAL.—The report for 1933 states that the expenditure had, by rigid economy, been reduced from £67,674 to £66,590. The income was £71,877. There was a considerable increase in out-patients and casualty cases—the former exceeded 95,000; the latter numbered nearly 40,000. There were 5259 in-patients, and 2951 major operations were performed. The immediate programme comprises, besides the erection of another block of the nurses' hostel at Hampstead, the provision of paying wards in the hospital, the removal of the kitchens from the basement to the top floor, and the conversion of the basement for the use of physicians, surgeons, and specialists. At the recent annual meeting Mr. George Verity, the chairman, stated that the first step in the programme was made possible by the munificent generosity of the vice-chairman, Mr. J. S. Elias.

OBITUARY

FRANCES MAY DICKINSON BERRY, M.D., B.S. Lond.

We regret to announce the death of Lady Berry, the wife of Sir James Berry, F.R.C.S., which occurred on Sunday, April 15th, at her home, Bramblebury, near Wendover.

Dr. Frances May Dickinson Berry was the daughter of Mr. Sebastian Dickinson, formerly M.P. for Stroud, and the sister of Sir Willoughby (now Lord) Dickinson. Born in 1857 she was educated at home, save for one year in Dresden, and studied medicine at the School of Medicine for Women attached to the Royal Free Hospital. She graduated with the M.B. degree in 1889, and two years later married Mr. (now Sir) James Berry. In 1892 she proceeded to the M.D. degree, and after post-graduate work in Vienna held resident appointments at the Belgrave Hospital for Children and the New Hospital for Women. In 1895 she took the B.S. degree, with honours, and for a time was assistant medical officer for education purposes to the London County Council. She then decided to practise as an anæsthetist, and held appointments as anæsthetist at the Royal Free Hospital and the Alexandra Hospital for Children.

LADY BERRY

[Photograph by Elliott and Fry.

The war brought Sir James Berry and his wife into well-deserved prominence for their distinguished Red Cross work in Serbia. Both of them had been for years keen travellers, and their annual holidays had been spent bicycling in, among European countries, Serbia, Dalmatia, and the Danubian districts, as well as in North Africa. When, therefore, the Royal Free Hospital established a Red Cross Unit in Serbia they were especially fitted by acquaintance with the country and with the manners of the inhabitants to take charge of the adventure. The experiences in surgery and epidemiology with which the Anglo-Serbian Hospital Unit met were various, and the practical difficulties to be surmounted were great. The story was later set out in a book by Lady Berry and her husband, with the assistance of other members of the Unit, where beneath the picture drawn we discern the courage and resourcefulness shown by the leaders. The Anglo-Serbian Unit arrived in Serbia in 1915 and found that their first work would be to instil some rudiments of hygienic method into the minds of the people, who were, as the authors said, "living on mud floors, disliking fresh air, suffering much from tuberculosis and diphtheria, careless about water-supply, and horribly tormented with worms." Into such a population, already suffering from war and imminently threatened with invasion, it was a great exploit to introduce the doctrines of sanitation. There was, however, at first little fighting, and early successes had resulted in Austrian prisoners. The work of these in collaboration with that of the Serbians led to the establishment of a rough-and-ready system of hygiene, as can be gathered from the book which gave a cheerful picture of an experiment in international amity. But within a year the Austrian invasion proved victorious and the Anglo-Serbian Hospital Unit was captured. Berry and his wife were treated with great consideration and subsequently took a British Red Cross Unit to Rumania, where their work again testified to their energy and enthusiasm.

At the end of the war Lady Berry for a time resumed her professional activities, while she served as president of the Medical Women's Federation, but of late years she and her husband have lived in retirement at their house near Wendover. She had been ailing for some two months, but latterly had manifested improvement. At the end of last week she had a sudden relapse, and died of pneumonia within 48 hours.

CECIL WILLIAM CUNNINGTON, M.R.C.S., D.P.H. Camb.

The death is announced at his residence in Kilburn of Dr. Cecil William Cunnington, a well-known practitioner in the Hampstead and Kilburn districts. Born in 1855 he received his medical training at King's College Hospital, where he was a successful student and Warneford Scholar, and became an Associate of the College. He passed the intermediate M.B. Lond. examination, but went no further towards graduation, taking the M.R.C.S. Eng. in 1883. He held various resident appointments, and was for a time house surgeon at the Royal Free Hospital, and some forty years ago commenced practice in the neighbourhood where he died. Dr. Cunnington's local activities were great. He early became a member of the Hampstead vestry, secured a seat on the borough council on its formation, and later became an alderman. He served on many district committees, showing special interest not only in hygienic matters but in the maintenance of libraries and the preservation of open spaces. The public concern at his death was displayed by the large congregation assembled at the funeral.

THE LATE DR. STANLEY MELVILLE

Dr. Arthur G. Phear writes: "May I be allowed to supplement your memoir of Stanley Melville by a reference to his love of flowers, gardens, and music? On the occasions of our visits to the Royal National Hospital at Ventnor it has been my privilege to play truant with him from the business of the board room and to wander through the grounds with the gardener, who delighted in displaying his special treasures to so congenial and appreciative a companion. He was intensely devoted to music and though, owing to his disability, he was debarred from performing himself, he took a keen and critical interest in the works of the older composers, and would comment on the solace and refreshment he derived from listening to the music of Bach, specially when played on the clavichord. It may not be out of place in this connexion to pay a tribute to the exquisite music provided by the organist and boys of the choir at the memorial service at All Saints, Margaret-street. Nothing could have been more perfect in itself, or more appropriate to the occasion. Mr. Vale, the organist, was a close friend of Stanley Melville, and the singers were undoubtedly expressing a sense of personal loss."

PANEL AND CONTRACT PRACTICE

A Review of National Health Insurance

It was enterprising of the Blackburn insurance committee to ask Sir George Newman to address insurance doctors and chemists at a local celebration of 21 years of health insurance, and to make his remarks on this occasion available to a wider audience. Sir George recalled that when the Health Insurance Bill was proposed in 1910 they were told there were three fatal blemishes in it: first the scheme was too expensive to be profitable; secondly the doctors would not coöperate, and if they did they would be an inferior part of the profession whose treatment would be perfunctory and inadequate; thirdly as many of the insured persons desired to be exempted, only those would be in it who wanted something for nothing. Within 20 years these fears had proved to be substantially false. It was Emerson who said :—

> "The lesson of life is to learn to put the meaning of the centuries and of the years over against the meaning of the days and hours."

Looking back after years or centuries, said Sir George, we could see the trend of men's work. More than 800 years ago the guilds—religious, merchant and craft—were with the manors and monasteries a means of coöperative defence against physical disability. The guilds were followed by the friendly society and the trade-union, with the result that to-day we live in the Golden Age of state assistance and coöperation. Between the Feeding of School Children Act of 1906 and the Local Government Act of 1929, Parliament enacted ten measures dealing with different kinds of social insurance. In little more than a generation the public health service had turned from reform of environment to reform of personal health, in fulfilment of Edmund Burke's splendid vision, "A working partnership between those who govern and those who are governed."

From the records of sickness of 16 million insured persons we had learned that about half the working population suffer from sickness in some form during the year; that 20 per cent. of those who claim sickness benefit do so on account of bronchitis pneumonia, or other respiratory disease, 13 per cent on account of indigestion or diseases of alimentary tract, 10 per cent. on account of rheumatic troubles, and a like number of injuries, accidents, and septic wounds. These four conditions accounted for more than half of the non-infectious sickness of the English people; plus the infective diseases they constituted the common enemy of the nation, more wasteful in time, money, and life than all the industrial strikes put together. After alluding to the steady decline in disease and increase in expectation of life, Sir George spoke of the immense advantage of health insurance in removing the chief deterrent of early and effective treatment. The insurance principle was, he said, a grand system of education for the people in the art of living. It was inconceivable that eight million persons should every year seek advice from their doctor without learning something about the avoidance and prevention of sickness; the doctor inquired into causation because it paid him best for his patient not to be ill. There was of course some imperfect work—this being an imperfect world, human beings were not infallible—but taken as a whole it was a system which gave half the adult population the inestimable advantage of coöperative medicine, not only under supervision of the contracting parties, medical and lay, but so designed as to meet the needs, both real and fanciful, of the insured person.

In this interesting address Sir George Newman was no doubt right in emphasising the freedom of the insured person from financial anxiety in case of illness as one of the greatest assets of national health insurance. It is curious how little the logic of this fact is brought home to the insured population. Insurance practitioners constantly hear their patients complain that they only have the insurance money coming in to live on. Is it not rather surprising that the majority of working men seem content to insure only through the Act for its ordinary benefit, and rarely, if ever, increase the amount payable weekly through the voluntary side of the approved society.

PUBLIC HEALTH

Puerperal Sepsis

A CIRCULAR letter dated April 13th from the Ministry of Health calls the attention of medical officers of health to the discontinuance of an arrangement for the bacteriological investigation of puerperal sepsis. The Departmental Committee on Maternal Mortality was so much impressed by the number of fatal cases of puerperal sepsis in which no source of infection had been traced that it suggested immediate steps to define the responsibility of the throat carrier and of infective conditions in persons in contact with the patient. By arrangement between the Ministry of Health and the Medical Research Council the services of a full-time bacteriologist were made available and Dr. Dora Colebrook was appointed by the Council and began work on Jan. 1st, 1932, in the new laboratories of Queen Charlotte's Hospital at Hammersmith. Her results show that certain puerperal fever cases are infected by a strain of *Streptococcus pyogenes* identical with that obtained from the respiratory tract of the doctor or nurse attending them; that in other cases the infecting strain is identical with that obtained from the patient's respiratory tract; that in a third group the strain is identical with those obtained from the respiratory tract both of the patient and of a contact. Cases of the last type are not very uncommon and allow of no decision as to the source of the infecting strain. Dr. Dora Colebrook's work continues although no longer in association with the Ministry of Health.

Opening a discussion last summer at the Dublin B.M.A. meeting, Dr. Leonard Colebrook said that in a group of 57 women admitted to Queen Charlotte's for puerperal infection by *S. pyogenes*, 12 per cent. were carrying these cocci in the nose only. Available data, he said, indicated that nose carriers of hæmolytic streptococci number no less than 4 per cent. of normal individuals in London during the spring. He spoke of a nurse working in a maternity hospital where cases of puerperal sepsis had been occurring sporadically for two years. This nurse had a slight discharge from her nose after an operation on the antrum two years previously, and this discharge was full of hæmolytic streptococci. The last case of puerperal infection sent to Queen Charlotte's was found to have a strain of streptococcus identical with that from the nurse's nose. Dr. Colebrook concluded that from his experience there are many sources of streptococcal infection: it may come from the mother herself, from another septic case, or from the nose or throat of someone attending her. It is too often overlooked, he remarked, that infection may come from some member of the household who is not present at the confinement—e.g., the husband with a sore-throat or a septic wound of his hand, the child with impetigo, a discharging ear, or a post-scarlatinal nose infection. Infective material from one of these sources may have contaminated a towel used by the midwife after washing her hands.

In an earlier letter to M.O.H.'s Sir George Newman pointed out that administrative difficulties not infrequently arise from bacteriological uncertainty about the strains of streptococcus in a particular case and a number of agglutinating sera available for the purpose has been steadily accumulating. These serums are available at the Ministry of Health for the rapid identification of strains. Although the arrangement with the Medical Research Council is now to cease, the value of bacteriological investigation in the problems which confront the medical officer of health in relation to the conduct of maternity homes and the suspension of midwives is still evident. The circular letter hopes that the M.O.H. will take every opportunity to obtain assistance on these points from bacteriologists attached to adequately equipped local laboratories. The M.O.H. desirous of obtaining the help of the Ministry can still do so by forwarding a short report of the cases of infection which have occurred and the bacteriological results, if any, which have been obtained.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED APRIL 7TH, 1934

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 6 (last week 3); scarlet fever, 2613; diphtheria, 1059; enteric fever, 11; acute pneumonia (primary or influenzal), 1404; puerperal fever, 55; puerperal pyrexia, 128; cerebro-spinal fever, 26; acute poliomyelitis, 2; encephalitis lethargica, 6; dysentery, 3; ophthalmia neonatorum, 68. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on April 16th–17th was as follows: Small-pox, 1 under treatment, 7 under observation (last week 11 and 1 respectively); scarlet fever, 1651; diphtheria, 1725; measles, 3648 (last week 3670); whooping-cough, 311; puerperal fever, 30 mothers (plus 10 babies); encephalitis lethargica, 258; poliomyelitis, 4; "other diseases," 101. At St. Margaret's Hospital there were 13 babies (plus 7 mothers, with ophthalmia neonatorum).

Deaths.—In 118 great towns, including London, there was no death from small-pox, 3 (0) from enteric fever, 162 (59) from measles, 12 (0) from scarlet fever, 51 (11) from whooping-cough, 49 (15) from diphtheria, 40 (10) from diarrhœa and enteritis under two years, and 89 (21) from influenza. The figures in parentheses are those for London itself.

Measles remains substantially unchanged, the figures for the last few weeks, working backwards, being 162, 153, 187, 157, 141, 130, 119, 110, 78. This week there were 18 fatal cases in Liverpool, 14 in Middlesbrough, 9 in Newcastle-on-Tyne, 7 in West Ham, 6 in Barnsley, 4 in Salford, and Stoke-on-Trent. The deaths from measles so far during the present year number 1506, compared with 459 during a similar period last year.

Willesden, Dewsbury, and Oldham each reported one death from enteric fever. Whooping-cough caused 6 deaths in Liverpool, 5 each in Salford and Sheffield, 4 in Birmingham. Five deaths from diphtheria were reported from Liverpool. Fatal cases of influenza were widely distributed among 42 great towns, the highest number of deaths being reported from Birmingham 6, Liverpool 5, Willesden, Hastings, Portsmouth, Southampton, Newcastle-on-Tyne, Sunderland, each 3.

The number of stillbirths notified during the week was 291 (corresponding to a rate of 44 per 1000 total births), including 47 in London.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Road Traffic Bill

MINISTER'S DEFENCE OF HIS PROPOSALS

IN the House of Commons on April 10th Mr. OLIVER STANLEY (Minister of Transport) moved the second reading of the Road Traffic Bill. He said that the problem of road accidents was one the gravity of which could not be exaggerated. He doubted, however, whether even now the general public were really alive to the terrible extent of the fatalities and accidents.

He wondered, for instance, whether the ordinary man realised that between that time (3.30 P.M.) and 11 P.M. when the Speaker would put the question that this Bill be read a second time, on the basis of the law of averages, 180 people would have met with an injury on the roads of this country.

The Bill was a proposal which the Government made for dealing, as far as any form of Statute could deal with this particular problem. There was a school of thought which said that there was no need to worry about restrictions, no need for users of the road to put up with anything, if only enough money was spent on the roads. He believed that to be dangerous nonsense. A great deal of time and ingenuity as well as money could be spent upon the roads, but in the end the roads would only be made safer, but not safe. Ignorance and folly could kill a man just as surely on a modern by-pass as on an old country road. He did not believe there was any possibility of finding any real solution of this problem unless all of them were prepared to bear burdens themselves, as well as impose burdens on others, and unless all of them were prepared in some degree to subordinate their personal convenience and desires to the general need of public security. This Bill was only a part and not necessarily by any means the most important part, of the action they would have to take if this problem of road accidents was to be solved.

The four principal proposals of the Bill, said Mr. Stanley, were a speed limit of 30 miles per hour in built-up areas, a test for new drivers, the establishment of pedestrian crossings, and amendments in the law of compulsory insurance. Looking back on the last four years they had to admit that the hopes which were then entertained of a reduction in the numbers of killed and injured on the roads had largely been falsified. Unfortunately in the last 18 months there had been unmistakable signs of a growth in the number of accidents, and because of that fact they had to survey the field once again. One heard many arguments as to speed being the important factor in accidents. Most people would agree that as a factor in accidents speed was only relative; but they must all agree that speed reduced the driver's power to deal with the unexpected. It was in the built-up areas that 75 per cent. of the deaths of pedestrians occurred. Pedestrians made up more than half of the total of people killed on the roads and about half of the pedestrians were children and old people. He asked hon. Members not to be led away by the argument that this Bill was a return to the old speed limit. This new proposal was quite different. The former speed limit failed because it did not accord with the view of reasonable people.

TESTS FOR DRIVERS

In regard to tests for drivers, it was true that a certain number of people would be unable to pass the test at all. There would be some whose physical condition would prevent them, some whose reactions were so slow and whose judgment was so bad that they were better off the roads; but the general run of people would eventually pass the test.

With regard to the machinery of the test he intended to approach at once the motor organisations. They had expressed complete hostility to this particular provision, but he would appeal to them to coöperate in setting up machinery for carrying out these tests. Of course, if they refused that was their business. There were alternative methods which could easily be adopted. The Bill gave power to the magistrates in case of a conviction for careless or dangerous driving to suspend the motorist's licence until he passed the test. Drivers of heavy vehicles would be required to obtain a special licence enabling them to drive that particular class of vehicle.

The decrease in fatal accidents as a result of the experiment of pedestrian crossings in the Department of the Seine in France had been so remarkable that he felt that he could not overlook the possibility of such an experiment in this country. As regarded the question of insurance, under the new provisions contained in the Bill the insurance company would become liable on their policy as soon as the injured person secured a judgment, if the car was being used within the terms of the policy. It would then be for the insurance company if they wished to repudiate to get the declaration from the court saying that they were entitled so to do, and they would only be able to get that declaration on the ground of non-disclosure of material facts. It shifted the onus in this case from the injured person to the insurance company.

THE PSYCHOLOGICAL ASPECT

Sir Ernest Graham-Little said he would restrict his intervention entirely to the medical and psychological aspects of the problem. The medical profession had a long experience of accidents, and while attention was confined to mechanical factors progress was slow, but when attention was directed to the human factor the improvement was immediate. It was to the neglect of the human factor in this Bill that he wished to draw attention, and he urged the Minister to realise the importance of including a medical test as well as a test of competence in driving. It was possible to make a discrimination between drivers who were likely to be mischievous and those who were not, and the tests, as was so often the case, were largely ignored in this country while they were adopted very much more widely in other countries. Their practical utility might, he thought, be conveniently gauged by some figures published two or three weeks ago in Paris by one of the most eminent psychologists in the world.

These figures showed that the frequency of accidents caused by taxis, private cars, and lorries between 1921 and 1932 increased by 145 per cent. A series of figures for the corresponding year furnished by the General Transport Company of Paris, which was responsible for the omnibuses and trams of that city, showed that the accidents due to collision were reduced by more than 30 per cent. and the gain to the company following these tests reached an average of 1,500,000 francs a year.

Somewhat similar figures were furnished in the case of some companies in America. In the Street Railway Omnibus Service of the Boston Elevated Railway accidents were reduced by 35 per cent. The figures in the case of the Milwaukee Electric Railway were reduced from 14·1 to 0·6 per cent. in a year.

The test, Sir Ernest continued, did more than reduce the rate of accidents. It sorted out the drivers who were likely to be mischievous from those who were not, and the register of selected persons fell to something like 3 per cent. where it had previously been 20 per cent. The saving in the cost of the wear and tear of vehicles again represented a very large sum. He was sure that an advance would be better made by following along the line of medical science, and he was equally sure that much of the accident-rate was caused by essential ignorance of quite simple biological facts on the part of motorists.

It was not perhaps, sufficiently realised that the time occupied in making a decision might make all the difference between a fatal accident and an escape. That was tested very carefully in a group of drivers, and it was found that the best driver gained a half per cent. as compared with the less experienced and less capable driver. That meant a saving of 30 ft. He could pull up at 30 miles an hour within a distance of 30 ft. less than the man whose reaction time was a second longer. The reaction time could be decreased. A decision could be retarded by a large number of quite innocent acts. A heavy dinner, a glass of beer, inattention, fatigue—all these unconscious factors might influence that very important circumstance.

The Bill could, he thought, be improved by paying some attention to the human factor which was aptly demonstrated by statistics to be responsible for a large proportion of accidents.

Sir Charles Oman said that there was a great deal to be said in praise of the Minister's proposed tests and examinations for motorists. He thought that the arguments produced against the proposal had been unconvincing. There was only one thing he would like to add, and that was a medical examination. Only a few weeks ago an epileptic motorist charged into a dense crowd watching the King drive away and killed four people. If that motorist had presented himself before a doctor he would probably have been detected. A person who was actually a drug-taker, or was showing signs of being a habitual drunkard, would also be detected by a medical man. The only thing that was wanted in addition to the tests proposed in the Bill was that there should not only be a test of driving but a doctor who, at the lowest possible fee, would say that the applicant for a licence was physically and mentally capable.

PAYMENT FOR EMERGENCY TREATMENT

Dr. Howitt said he welcomed the Bill because he believed that immediate legislation was necessary if the appalling casualties on the roads were to be reduced. The Minister was aware that many members of the House were anxious that the Bill should include a provision embodying the principle of Lord Moynihan's Road Traffic (Emergency Treatment) Bill which had passed through all its stages in the House of Lords. That Bill made provision for remuneration of registered medical practitioners and hospitals for emergency treatment only. Hospitals and medical men were thoroughly dissatisfied to-day with their remuneration for such emergency treatment, and their dissatisfaction was shared by people all over the country. It was not right that emergency treatment should be given by hospitals and doctors and not be paid for. Everybody would agree that family doctors were very hard-working men who were not particularly wealthy or over-paid. The lives of many of these doctors were rendered miserable to-day by casualties on the main roads. He was afraid that a lot of medical men had had to give up their houses on or near main roads because they were being perpetually called out on Sundays and were losing money, just as was the case in regard to the hospitals, in connexion with the supply of bandages and splints. They practically never got a penny of remuneration or one subsequent word of thanks. He did not think that the reason for this was sheer ingratitude on the part of the patients, but a fear of the law if they got into communication with the doctor. They feared that if they paid anything they were putting themselves in a false legal position. The difficulty was how the contribution to hospitals and medical men for emergency treatment was to be found. After a great deal of discussion the conclusion had been arrived at that a very slight increase in the premium for compulsory insurance for third-party risks would cover emergency treatment by doctors and hospitals. The cost of the extra premium would be very small.

Mr. McKeag said that Dr. Howitt had mentioned a real grievance which he felt sure that the Minister of Health would do his best to meet, and in regard to which he thought that Dr. Howitt would have the support of the majority of Members if he raised the matter in Committee.

Mr. Lovat-Fraser begged the Minister of Transport to deal with the horrible, shrieking motor-horns in use at present. He said that they were thoroughly bad for the nerves, and were becoming more numerous.

JUSTICE TO HOSPITALS

Mr. STOREY said that the greatest blot on the Bill was that it did nothing to secure justice for the voluntary hospitals, and left on their shoulders a very heavy burden due to the cost of treatment of road accidents. The Minister of Transport had reminded the House that between the time he was speaking that afternoon and 11 o'clock that night 180 persons would be injured on the roads, but he had not reminded them that those cases would be treated by the hospitals which would not be able to recover more than one-half of the cost.

The House would recall that before the 1930 Act was passed it was estimated that road accident cases cost voluntary hospitals no less than £230,000 per annum, and of that sum the hospitals were only able to recover some £26,000. The House might not realise, however, that although the 1930 Act made provision for hospitals to recover up to £25 where negligence could be proved against the driver it utterly failed in every way to do justice to the hospitals. In 1931 it was estimated that road accidents still cost the voluntary hospitals of the country £230,000, but they were only able to recover £34,000. It was true that there were outstanding claims of some £58,000, but anyone who knew how difficult it was to recover those sums would realise that such claims were very doubtful assets indeed. It was very difficult to maintain voluntary hospitals at the present time, particularly in distressed areas, where contributions were made in small sums of *1d.* or *2d.* a week from working-class people; and it was quite wrong that those who had subscribed this money should have to wait for treatment owing to the pressure on the hospitals due to road accidents.

Mr. Storey suggested that a charge should be made on the Road Fund to meet cases of this kind, and that the money should be paid to some central body which would recoup the voluntary hospitals for their charges, the hospitals making over to that body any right they might have against any driver who had been proved to be negligent. He hoped that the Minister during the Committee stage of the Bill would seize the opportunity of doing justice to the voluntary hospitals. The voluntary hospital system was an asset which this country and the House should do everything to support.

THE GOVERNMENT'S REPLY

Lieut.-Colonel HEADLAM (Parliamentary Secretary to the Ministry of Transport), replying to the debate, said there was no intention of re-establishing a general speed limit for private cars such as existed before 1921. It was, however, perfectly clear that the larger number of accidents taking place at present occurred on roads in built-up areas. So long as that was the case it was desirable to make it less likely that accidents of that kind should occur. The Government thought that by imposing a speed limit in built-up areas no serious hardship would be imposed on motorists. The real point of the Bill was not that the Government hoped by it to do away with all the accidents and troubles on the roads at present, but that its effect would be to reduce accidents and inculcate in the people of the country the necessity for care and caution on the roads. The Minister was ready to consider in Committee any suggestions by Members for the improvement of the Bill. Matters such as those concerning the hospitals and the doctors could well be considered in *Committee*.

The Budget Statement

In the House of Commons on Tuesday, April 17th, Mr. CHAMBERLAIN, Chancellor of the Exchequer, made his annual Budget statement. He said that a year ago he had to report a deficit of just over £32.000.000; this year he was able to announce a surplus of £31.147,860. The revenue receipts had exceeded the estimate by £25·8 millions. Of this Customs and Excise had contributed £17.000,000. Income-tax at £229,000.000 and surtax at £52,500.000 were within 0·7 per cent. of the estimate.

Mr. Chamberlain announced that the general preference on all colonial sugar reaching the United Kingdom would be reduced to the old rate of approximately 3*s.* 9*d.* per cwt. The additional quota preference of 1*s.* per cwt. would be replaced by a new quota preference of 3*s.* per cwt. on a fixed quantity of 360,000 tons per annum. This provision would remain in operation for three years.

As from Jan. 1st next the present motor vehicles tax of £1 per horse-power would be reduced by 25 per cent. to 15*s.* per horse-power. There would be a corresponding reduction in the duties payable on motor cycles. The cost of this reduction would be £2,200,000 in 1934–35 and £4,000,000 in a full year. Under the existing law this loss would be borne as to two-thirds by the Road Fund and as to one-third by the Exchequer. Special arrangements would be made under which the Exchequer share of the duties on private vehicles (normally one-third) would be subject this year to a minimum of £5,000,000. The fee of 10*s.* or 5*s.*, as the case might be, charged since 1924 for the surrender of licences, would be abolished.

Dealing with the manner in which he proposed to deal with the Budget surplus Mr. Chamberlain said that one-half of the cuts in salaries made in 1931 would be restored as from July 1st. Excluding the unemployed, the cost of this provision to the Exchequer in a full year would be £5,500,000, and in the current year £4,000,000. The whole of the cuts in unemployment benefit would be restored. On the assumption that the Unemployment Bill would become law by the end of June next the new rates of benefit would take effect as from July 1st next. There would be a corresponding alteration in the rates of transitional payments (where the needs of applicants required it) and £3,600,000 would be allowed for this in the current year. The cost of the restoration of the 10 per cent. cut in unemployment benefit was estimated at £4·8 millions in a full year. These proposals left a surplus of £21·3 millions.

Out of the £81,500,000 of extra taxation imposed in 1931 the income-tax payers found no less than £57,500,000, or 70 per cent. Although their burdens were already heavy, the income-tax payers had shouldered an extra 6*d.* on the standard rate of tax, there had been a general reduction in allowances, and a surtax of 10 per cent. on the larger incomes. Moreover, all these increases of taxation took effect from April, whereas the cuts only became operative in the autumn. It must not be forgotten that since 1931 many income-tax payers had also suffered a further serious reduction in their incomes owing to the operation of the conversion loan. The case for some remission was therefore overwhelming. The only question was as to what form the remission should take. In deciding the form he thought he ought to consider the effect of any remission, not merely on the individual taxpayer, but upon the country as a whole. He had come to the conclusion that the relief which would confer the most direct benefit on the country, which would have the greatest psychological effect, and which would impart the most immediate and vigorous stimulus to trade and employment, would be a reduction in the standard rate of income-tax. Accordingly he proposed to remove the 6*d.* imposed in 1931 at a cost of £20,500,000 this year and £24,000,000 in a full year.

Summarising the Budget, Mr. Chamberlain said that the final balance showed an estimated revenue for 1934–35 of £706,500.000 and an estimated expenditure of £705,700,000, leaving a prospective margin of £800,000.

HOUSE OF COMMONS

THURSDAY, APRIL 12TH

Woman's Detention in Mental Ward

Mr. PIKE asked the Minister of Health whether his attention had been called to the circumstances attending the death of Mary Hedley, aged 60 years, a married woman, of New-street, Sheffield; and if it was the intention of His Majesty's Government to institute inquiries into the operation of the Lunacy Acts with a view to ensuring that certificates declaring persons to be of unsound mind should not be issued until indisputable medical evidence had been established.—Sir HILTON YOUNG replied: There is, I think, some misapprehension about the facts of this case. It appears from the press report of it that, on the strength of a medical certificate from the district medical officer describing this woman's condition as "bronchitis and unsound mind," she was removed by the general relieving officer to the hospital under the provisions of Section 20 of the Lunacy Act with a view to her being kept under observation in the mental ward. The patient died there before any question of further formal proceedings for certification under the Lunacy Act arose and she was never certified. In these circumstances, there is no case for inquiry into the operation of the Lunacy Act.

Mr. PIKE: Does not the right hon. gentleman think that in view of the present circumstances which permit an officer of a public assistance committee to issue an order for detention in a mental ward, no person should be admitted as a mental case until there has been a thorough medical inquiry and the mental condition of the person has been established?

Sir HILTON YOUNG: I do not think I can accept the suggestion which is contained in the hon. Member's supplementary question. He will see that in this particular case there was, as a matter of fact, no question of certification.

Provision of Meals for School-children

Mr. THOMAS WILLIAMS asked the Parliamentary Secretary to the Board of Education if he would furnish a list showing those authorities which, under Sections 82 to 84 of the Education Act, 1921, provided meals, respectively, only on days when the school met, on days when the school met and Saturdays and Sundays, and on school days, Saturdays and Sundays, and during holidays.—Mr. RAMSBOTHAM replied: The answer is as follows: The preparation of a complete statement containing the information required would involve the expenditure of a disproportionate amount of time and labour. The following table gives a summary, by types of local education authority, of the periods during which school meals are provided in the different areas.

Days per week on which meals are provided.	Number of. local education authorities.			
	Counties.	Non-county boroughs.	Urban districts.	County boroughs.
7 days and holidays	—	2	—	4
7 ,, not ,,	—	—	—	1
6 ,, and ,,	1	9	7	18
6 ,, not ,,	—	—	1	—
5 ,, and ,,	4	13	8	21
5 ,, not ,,	8	23	8	16
5 ,, a week* ..	3	8	2	8
Miscellaneous case †	—	3	1	5

* In these areas it appears that feeding is not continued during the holidays, but the Board have no definite information.

† These include one county borough where breakfasts are provided on five days a week and holidays, and dinners on six days a week and holidays. In the remaining eight areas milk is given on five days a week and not in holiday periods, but other meals are provided in those areas as follows:—

2 boroughs ..	Cod-liver oil and malt and/or emulsions on	7	days a week and holidays.
1 borough ..	Ordinary meals on ..	7	
1 urban district	,, ,, ,, ..	6	
2 county boroughs	,, ,, ,, ..	5	
1 county borough	,, ,, ,, ..	6	
1 ,, ,,	,, ,, ,, ..	7	

Use of Dangerous Drugs for Slimming

Captain ERSKINE-BOLST asked the Home Secretary whether he had any information as to the time that would elapse before action was taken to place on the appropriate poisons schedule dinitro-phenols and dinitro-cresols, drugs the use of which for slimming purposes had proved fatal in several instances recently.—Sir J. GILMOUR replied: The steps necessary to add these drugs to Part I. of the existing Poisons Schedule have already been taken and notice to that effect will appear in to-morrow's *London Gazette*. The Statute requires that one month shall elapse from the date of the notice before the provision comes into effect.

India (Defence Forces' Medical Service)

Captain ELLISTON asked the Secretary to the Treasury whether he could report the result of consultations with the Government of India regarding the recommendations of the Warren Fisher Committee in reference to the Royal Army Medical Corps and other medical services of the defence forces.—Mr. HORE-BELISHA replied: Agreement has now been reached and the Government decisions on the recommendations of the Committee will be announced by the end of this month.

MONDAY APRIL 16TH

Pensions and Institutional Treatment

Mr. THORNE asked the Minister of Health if he was aware that, when a pensioner went into a hospital or institution which received grants from either the Government or the local authority in which the hospital or institution was situated, the pension inured to the State, and that no portion was paid to the local authorty or institution while the pensioner was an inmate; whether he had recently received any representations from local authorities asking for an alteration in this practice; and, if so, whether he had any intention of introducing legislation.—Mr. SHAKESPEARE (Parliamentary Secretary to the Ministry of Health) replied: As regards the first part of the question, the position is that under the provisions of the First Schedule to the Widows', Orphans' and Old Age Contributory Pensions Act, 1929, a pensioner who becomes an inmate of a poor-law institution, other than a pensioner who enters an institution for the purpose of obtaining medical or surgical treatment and continues to require such treatment, is disqualified for the receipt of a pension. There is no provision in the law for the transfer of any portion of the pension to the poor law authorities. As regards the second part of the question, I have received no representations recently in the sense suggested by the hon. Member and the last part of the question does not, therefore, arise.

Nursing Services in India

Dr. O'DONOVAN asked the Financial Secretary to the War Office if the Army Council considered British lady nurses of the Queen Alexandra's Military Nursing Service for India ineligible for appointment to the post of chief principal matron at Army headquarters, India; and if appointments to the post were to be confined, for the future, to British lady nurses of the Queen Alexandra's Imperial Military Nursing Service.—Sir S. HOARE replied: Members of both the British and the Indian nursing services are eligible for the post in question, and the appointment is made on the merits of the candidates from either service on each occasion.

TUESDAY, APRIL 17TH

Milk Tests in Scotland

Mr. LEONARD asked the Secretary of State for Scotland what action had been taken by the Scottish Milk Marketing Board to ensure that milk intended for liquid consumption should be adequately tested for the proper maintenance of a pure milk standard.—Sir GODFREY COLLINS replied: The Board have prescribed a minimum butter fat content standard of 3·4 per cent. The question of fixing a standard for cleanliness is engaging the attention of the Board.

Milk-supplies to School-children

Sir WILFRID SUGDEN asked the Parliamentary Secretary to the Board of Education the numbers of children in elementary schools in Essex and also in England and Wales who received during their attendance at school a tumbler of milk daily morning and/or afternoon; and what was the test of elimination whereby others in the same schools were not so supplied.—Mr. H. RAMSBOTHAM replied: The numbers of school-children in the geographical county of Essex, and in England and Wales as a whole, who were provided with milk by local education authorities during the month of February last, were 1363 and 184,493 respectively. In addition, it is estimated that about 21,000 school-children in the geographical county of Essex and 900,000 in England and Wales as a whole, receive milk daily under voluntary milk schemes administered by the National Milk Publicity Council. The selection of children to receive milk depends on a variety of factors, such as, for example, the condition of the child, the willingness or unwillingness of the parents to pay where able to do so, or the willingness of the parent to allow the child to receive milk.

Slum Clearance

Sir PERCY HARRIS asked the Minister of Health in how many slum-clearance schemes had the work of clearance been actually commenced for the year ended March 31st, 1934, or the nearest available date; and how many persons therefrom had been actually rehoused.—Sir E. HILTON YOUNG replied: The number of clearance schemes, that is, confirmed orders or purchases by agreement in the course of the year ended March 31st last was 631, involving the demolition of 16,375 houses and the building of replacement houses for 73,718 persons, but I am not able to state the extent to which the work of clearance and rehousing had gone by the end of the year.

Disposal of London Refuse

Mr. MCENTEE asked the Minister of Health whether the advisory committee on London refuse had finished their work and reported; and, if so, would he state the nature of their report.—Sir E. HILTON YOUNG replied: I understand that the committee have completed their inspection of places where refuse is handled in the county, or disposed of outside the county, and also their inquiry into the collection and disposal of house refuse and the cleansing of streets and gullies in all but one of the city and metropolitan borough councils; and that the committee hope shortly to be able to submit a report in the first place with regard to the disposal of London refuse.

Health Insurance: Medical Benefit

Mr. THORNE asked the Minister of Health if he could state, owing to continued unemployment, at the end of December, 1933, the numbers of persons that had been denied medical benefit from their various approved societies.—Sir E. HILTON YOUNG replied: The returns which have now been received from approved societies indicate that the number of members who after a period of prolonged unemployment were continued in insurance during 1933 by virtue of section 1 (5) of the National Health and Contributory Pensions Act, 1932, but ceased to be entitled to medical benefit on 31st December last (though continuing to be insured for pensions purposes) is approximately 125,000. This number will, however, be substantially reduced by reinstatements to medical benefit, notifications of which are now being received from societies at the rate of several hundreds a week.

Small-pox at Blackburn

Mr. GROVES *asked the Minister of Health whether the* medical officers of the Ministry reported the form of small-pox recently notified at Blackburn to have been of the variola major or the variola minor type.—Sir HILTON YOUNG replied: I am advised that the recent outbreak of small-pox in Blackburn was an outbreak of variola major.

Mr. GROVES asked the Minister of Health how many cases of small-pox were wrongly diagnosed in connexion with the recent outbreak at Blackburn; and whether it was proposed to take proceedings against the medical attendant or attendants concerned for failing to notify these cases as small-pox.—Sir HILTON YOUNG replied: Four of the early cases were originally diagnosed as chicken-pox. The answer to the second part of the question is in the negative. An error in diagnosis does not constitute an offence under the Infectious Disease (Notification) Acts.

Mr. GROVES asked the Minister of Health whether he was aware that the first case which led to the recent outbreak of small-pox at Blackburn was a man employed at a cotton-mill where he handled cotton daily; and whether the evidence indicated that he contracted the disease in the performance of his duties.—Sir HILTON YOUNG replied: The answer to the first part of the question is in the affirmative. I have no satisfactory evidence on the second part.

MEDICAL NEWS

Royal College of Surgeons of England

At a meeting of the council held on April 12th, with Sir Holburt Waring, the president, in the chair, the Jacksonian prize for 1933 was awarded to Mr. Edgar Samuel John King, F.R.C.S., of Melbourne Hospital and Melbourne University, for his essay on the pathology, diagnosis, and treatment of localised rarefying changes in bones. A certificate of honourable mention for an essay on the same subject was awarded to Mr. H. Jackson Burrows, F.R.C.S., of St. Bartholomew's Hospital. The Jacksonian prize subject for 1934 is the pathology, diagnosis, and surgical treatment of the various forms of splenomegaly, and for 1935 the pathology, diagnosis, and treatment of intrathoracic new growths, excluding neoplasms of the œsophagus.

The John Hunter medal, with the triennial prize for 1931–33, was awarded to Dr. Dorothy S. Russell, of the London Hospital, for her work on the morbid histology of the kidney and brain.

Dr. G. A. Buckmaster (Bristol) and Mr. G. F. Stebbing (London), being members of 20 years' standing, were elected to the fellowship. Diplomas of membership were granted to T. S. Heslop (Manchester) and M. S. Shin (University College). Diplomas in tropical medicine and hygiene were granted jointly with the Royal College of Physicians to the following:—

A. C. Banerjee, P. P. Bhavnagri, S. A. B. Black, I. E. Dirckze,
V. L. Ferguson, Emily C. Greenfield,
Mayne, K. S. Menon, T. H. L. Montge
H. A. F. Sallam, M. F. Seth, F. J. Sladen
Somers, A. L. Stuart, T. H. Williams,
and K. E. Yuill.

The regulations for examinership in anatomy were altered so that in future examiners in anatomy both for the fellowship and for the membership will be elected from persons holding a medical qualification in this country; previously only fellows examined in anatomy for the fellowship, and only fellows *or members* for the membership. Mr. F. M. Stent was appointed assistant secretary to the examining board in England.

University of London

Four lectures on the integration of the circulation will be given by Dr. R. J. S. McDowall, professor of physiology in the University, at King's College, Strand, W.C., on Thursdays, May 3rd, 10th, 17th, and 24th at 5 P.M. Admission is without ticket.

Eight lectures on the history of physiology are to be given at University College, Gower Street, W.C., by Dr. Charles Singer, professor of the history of medicine in the university, and Dr. K. J. Franklin, lecturer in physiology at Oriel College, Oxford. The first three, by Prof. Singer, will be at 5 P.M. on April 30th, and May 1st and 2nd, and the remainder, by Dr. Franklin, at the same hour on May 7th, 8th, 14th, 15th and 22nd. Admission is without ticket.

The Bayliss-Starling scholarship, of an annual value of about £120, is tenable at University College, and applications are invited before May 12th. The successful candidate will be required to follow a course of training in the principles and methods of research in physiology and/or biochemistry. Particulars will be found in our advertisement columns.

Metropolitan Hospital: Proposed Incorporation

The appeal for £30,000 for repairs and to pay off the debt has produced £22,000. At the recent annual meeting it was decided to incorporate the hospital as a company limited by guarantee. It was stated that the present members of a committee of management might be liable for unlimited sums, a consideration which has recently *led to a refusal to serve on the committee.*

Salford Royal Hospital

Last year there were 4031 in-patients who stayed on the average 20·48 days. There were 29,459 out-patients, an increase of 1180. Traffic-accident patients cost £1087, of which only £221 was recovered. The out-patients' department, built in 1911, is now inadequate, but lack of means prevents extensions.

Medical Tour in the Rhineland

A medical tour of Rhineland spas is being arranged for Whitsuntide. It will begin on May 18th and end on the 28th. Further particulars may be had from Mr. R. O. Rohme, 90, Sheaveshill-avenue, Colindale, London, N.W.9.

Society for Relief of Widows and Orphans of Medical Men

At a quarterly court of directors held on April 11th the President, Mr. V. Warren Low, being in the chair, an application for relief was considered from the widow of a member who had just died. He had been elected a life member in 1921 and the widow was left practically destitute with nine children, four under 16 years of age. The court voted her a yearly grant of £60 for herself and of £50 a year for each child under 16, a total of £260. She will also receive at Christmas the usual present of £10 for herself and £40 for the four children. Membership of the Society is open to any registered medical practitioner, who at the time of his election is resident within a 20-mile radius of Charing Cross. The annual subscription ranges from two to four guineas, according to the age of the candidate. Particulars from the secretary, at 11, Chandos-street, London, W.1.

Institute of Medical Psychology

This institute in London, formerly called the Tavistock Clinic, has received an anonymous donation of £300 "to start research work on the remedial treatment of children who suffer nervous troubles as an after-effect of assault." It has also received an offer from a medical man who undertakes to bequeath £100 to the institute if 29 other persons will do the same. The arrangement, he suggests, would be a "gentleman's agreement," and the bequests would be revocable in the event of "difficult circumstances."

It is stated that 77 children from London County Council schools have been referred to the institute during the past 12 months, 15 being sent for consultation only. Of those who received treatment, "satisfactory adjustment" was effected in 23 per cent., "partial adjustment" in 16 per cent., while 46 per cent. were still undergoing treatment at the end of the period. The remaining 15 per cent. are described as either unsuitable or affected by uncoöperative parents.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, April 23rd.

Odontology. 8 P.M. Paper. Dr. Franz Duyvensz (Amsterdam): Saliva. Mr. F. W. Broderick will open the subsequent discussion.

TUESDAY.

Medicine. 4 P.M. Clinical Meeting at University College Hospital, W.C. 4 P.M. Cases at the Hospital. 5 P.M. Tea in the Refectory, Medical School. 5.15 P.M. Discussion in the Lecture Theatre of the Medical School. Cases: Dr. F. J. Poynton: 1. Hepatomegaly and Splenomegaly; ? Lymphadenoma. Dr. J. W. McNee: 2. Acute Lymphadenoma with Pleural Effusion. 3. Lead Neuritis. 4. Multiple Neuro[illegible]. Dr. Kenneth Harris: 5. Chr[illegible] 6. Chronic Pulmonary T[illegible] Amylosis. 7. Aortic Aneurysm with Portal Cirrhosis. Dr. K. Harris and Dr. P. Kerley: 8. Vena Azygos Lobe with Hæmoptysis. 9. Vena Azygos Lobe in a Child with Chronic Bronchitis. Dr. Saxby Willis: 10. Aortic Aneurysm and Syphilis of Lung. Dr. A. Hall: 11. Congenital Heart-block and Peroneal Atrophy. Mr. G. E. O. Williams: 12 and 13. Pain of Vascular Origin in the Toes Relieved by Alcohol Injection. Mr. C. W. Flemming: 14. Recurrent Abscesses in Neck. Mr. C. Dee Shapland: 15–18. Fundus Oculi Changes of Medical Interest. Dr. L. P. E. Laurent: 19. Myasthenia Gravis (for Dr. C. Bolton). 20. Sarcoma of Spleen and Glands. 21. Granular Kidney following Acute Glomerular Nephritis. 22. Intracranial Aneurysm with Signs of Pressure on Pons. Dr. H. P. Himsworth: 23. Hæmochromatosis. 24. Parathyroid Deficiency. 25. Xanthoma Diabeticorum. Mr. Julian Taylor: 26. Chloroma. Dr. W. J. Pearson: 27. Congenital Morbus Cordis with ? Adherent Pericardium. 28. Hirschsprung's Disease Improved by Sympathectomy.

WEDNESDAY.

Comparative Medicine. 5 P.M. Discussion on the Results of Suture of Divided Nerves, to be opened by Sir Charles Ballance and Prof. John Beattie.

THURSDAY.

Urology. 8.30 P.M. Discussion on Anæsthesia in Urinary Surgery, to be opened by Dr. H. Featherstone and Prof. C. A. Pannett. Members of the Section of Anæsthetics are specially invited to attend.

FRIDAY.

Epidemiology and State Medicine, and Psychiatry. 8 P.M. Special Discussion on the Value of the Treatment of Mental Deficiency, to be opened by Dr. F. C. Shrubsall, Dr. W. Rees Thomas, and Dr. Noel Burke.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, April 23rd.—8.30 P.M., Discussion on Failures of Gastric Surgery, to be introduced by Dr. John Ryle, Mr. A. J. Walton, and Dr. Eustace Callender.

MEDICO-LEGAL SOCIETY.

THURSDAY, April 26th.—8.30 P.M. (at 11, Chandos-street, W.), Mr. Claud Mullins: How Should Sexual Offenders be Dealt With.

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 1, Upper Montague-street, Russell-square, W.C.

FRIDAY, April 27th.—5 P.M. (Fever Hospital Medical Services Group), Discussion on the Relationship of Measles and Whooping-cough to Chronic Inflammatory Conditions of the Chest, to be opened by Dr. C. D. Agassiz, Dr. G. Jessel, and Dr. J. E. McCartney, dealing respectively with the clinical, radiological, and pathological aspects of the subject. Members of the Tuberculosis, School Medical, and M. and C. W. Groups are invited to be present.

ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY.

WEDNESDAY, April 25th.—5 P.M. (49, Leicester-square, W.C.), Dr. Sibyl G. Horner: Industrial Dermatosis.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, April 23rd, to SUNDAY, April 29th.—BRITISH RED CROSS CLINIC FOR RHEUMATISM, Peto-place, N.W. Tues. and Thurs., at 8.30 P.M. Course in Rheumatism. ROYAL EYE HOSPITAL, St. George's-circus, S.E. Course in Ophthalmology. Afternoons.—SAMARITAN HOSPITAL, Marylebone-road, N.W. Week-end Course in Gynæcology. All day Sat. and Sun.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, W. Dr. A. E. Clark-Kennedy: Lecture on Cardiac Irregularity, on Tues., at 2.30 P.M. Dr. Philip Ellman: Lecture on Suppurative Diseases of Lungs, on Wed., at 8.30 P.M. Mr. E. A. Peters: Lecture on Septic Tonsils, Nasopharyngitis, and its Results, on Wed., at 4 P.M. (free to Members and Associates of the Fellowship of Medicine and open to non-members). Dr. Philip Ellman: Lecture on Industrial Diseases of Lungs, on Fri., at 8.30 P.M.—PANEL OF TEACHERS. Individual clinics in various branches of Medicine and Surgery are available daily by arrangement with the Fellowship. Courses of instruction, clinics, &c., arranged by the Fellowship of Medicine are open only to Members and Associates, unless otherwise stated.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.

DAILY.—2 P.M., Operations, Medical and Surgical Clinics.

MONDAY, April 23rd.—10 A.M., Skin Clinic, Medical Wards. 11 A.M., Surgical Wards. 2 P.M., Gynæcological and Surgical Wards, Eye and Gynæcological Clinics.

TUESDAY.—10 A.M., Medical Wards. 11 A.M., Surgical Wards. 2 P.M., Throat Clinic. 4.15 P.M., Lecture, Mr. Green-Armytage: Post Maturity.

WEDNESDAY.—10 A.M., Medical Wards, Children's Ward and Clinic. 2 P.M., Eye Clinic.

THURSDAY.—10 A.M., Neurological and Gynæcological Clinics. 11.30 A.M., Fracture Clinic. 2 P.M., Eye and Genito-urinary Clinics. 4.15 P.M., Lecture, Mr. Batchelor: Head Injuries.

FRIDAY.—10 A.M., Skin Clinic. 12 noon, Lecture on Treatment. 2 P.M., Throat Clinic. 4.15 P.M., Lecture, Dr. Konstam: Megalocytic Anæmia.

SATURDAY.—10 A.M., Medical and Surgical Wards, Children's and Surgical Clinics.

The Lectures at 4.15 P.M. are open to all medical practitioners without fee.

HOSPITAL FOR EPILEPSY AND PARALYSIS, Maida Vale, W.

THURSDAY, April 26th.—3 P.M., Dr. Blake Pritchard: Clinical Demonstration.

ST. MARY'S HOSPITAL INSTITUTE OF PATHOLOGY AND RESEARCH, Paddington, W.

THURSDAY, April 26th.—5 P.M., Mr. Hugh W. Bell Cairns: Intracranial Surgery.

ST. PAUL'S HOSPITAL, Endell-street, W.C.

WEDNESDAY, April 25th.—4.30 P.M., Mr. W. K. Irwin: Diagnosis and Treatment of some Important Bladder Conditions.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.

TUESDAY, April 24th.—3.15 P.M., Dr. C. Gouldesbrough: Spinal Abnormalities.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.

Monday, April 23rd, to Saturday, April 28th.—Second Week of Intensive Course in Laryngology, Rhinology, and Otology.

LEEDS GENERAL INFIRMARY.

Tuesday, April 24th.—3.30 P.M., Dr. Cooper: X Ray Therapy.

UNIVERSITY OF BIRMINGHAM.

Tuesday, April 24th.—3.30 to 5 P.M. (at the Children's Hospital), Dr. G. P. Mills: Demonstrations of Orthopædic Cases.

Wednesday, April 25th.—4 P.M. (in the Lecture Theatre of the Medical Faculty Buildings), Prof. E. D. Adrian: The Activity of Nerve Cells. (First of Two Lectures).

Thursday.—4 P.M., Dame Louise McIlroy: The Toxæmias of Pregnancy. (First of Two Ingleby Lectures.)

Friday.—3.30 to 5 P.M. (at the Queen's Hospital), Dr. Douglas Marsh: Diseases of the Tonsils and their Appropriate Treatment.

MANCHESTER ROYAL INFIRMARY.

Tuesday, April 24th.—4.15 P.M., Dr. F. E. Tylecote: Undulant Fever and other Unusual Pyrexias.

Friday.—4.15 P.M., Mr. J. P. Buckley: Demonstration of Surgical Cases.

GLASGOW POST-GRADUATE LECTURES.

Wednesday, April 25th.—4.15 P.M. (at the Royal Infirmary), Mr. J. A. C. Macewen: Surgical Cases.

Appointments

Kitson, J. H., M.B., Ch.B. Manch., has been appointed Medical Officer of Health and School Medical Officer, Todmorden.

London County Council Hospital Staff.—The following appointments, promotions, and transfers are announced. A.M.O. (I.) and (II.) = Assistant Medical Officer, Grades I. and II.

Fish, R. H., M.B. Lond., Senior A.M.O., II., High Wood Hospital for Children.

Begg, N. D., M.D. Aberd., A.M.O., I., North Eastern.

Cunningham, A. A., M.B. Dubl., A.M.O., I., Joyce Green.

Macfarlane, L. H., M.D. Lond., A.M.O., I., Northern.

Taylor, I., M.B. Lond., A.M.O., I., Grove.

Scholes, J. L., M.D. Melb., A.M.O., II., Queen Mary's Sidcup.

Jones, A. N., M.B. Liverp., A.M.O., II., St. Luke's Chelsea.

Turnbull, H. I., M.B. Sydney, A.M.O., II., Holborn and Finsbury Institution.

Cussen, K. R., M.B. Melb., A.M.O., II., Archway.

Cardno, J. A., M.B. Aberd., A.M.O., II., St. Mary, Islington.

Certifying Surgeons under the Factory and Workshop Acts: Bromley, E., M.B., B.S. Durh. (Arnesby, Leicester); McMichael, G. B., L.R.C.P. Lond., M.R.C.S. (Vowchurch, Hereford).

Vacancies

For further information refer to the advertisement columns

Aberdeen Royal Infirmary.—Asst. M.O. for Radium Dept.

Altrincham General Hospital.—Jun. H.S. At rate of £120.

Ashton-under-Lyne District Infirmary.—Reg. Surg. O. Also H.S. £200 and £150 respectively.

Birmingham, Canwell Babies' Hospital.—Res. M.O. At rate of £250.

Birmingham, Maternity and Child Welfare Dept.—Three Temp. M.O.'s. Each £10 per week.

Birmingham, Selly Oak Hospital.—Cas. O. At rate of £200.

Birmingham University Faculty of Medicine.—Lecturer in Bacteriology. £400.

Bradford Royal Infirmary.—Res. Surg. O. £225. Also H.P. and two H.S.'s. Each at rate of £135.

Bridgend, Glamorgan County Mental Hospital.—Jun. Asst. M.O. £350.

Burnley, Victoria Hospital.—H.P. At rate of £150.

Cardiff Royal Infirmary.—H.P. and H.S. Each at rate of £50.

Cheltenham General and Eye Hospital.—H.S. £200.

Chester Royal Infirmary.—Hon. Asst. Radiologist.

Dewsbury and District General Infirmary.—Part-time Hon. Pathologist.

Durham County Hospital.—H.S. £150.

Golden Square Throat, Nose, and Ear Hospital, Golden-square, W.—H.S. £100.

Grimsby Corporation Hospital and Sanatorium.—Res. Med. Asst. £350.

Guy' [illegible] *School, S.E.*—Dental Travelling Scholar- [illegible]

Hac [illegible] *'reet, Homerton, E.*—Asst. M.O. £250.

Hos [illegible] *Great Ormond-street, W.C.*—Physician [illegible] so Surgeon.

Hor [illegible] Res. M.O. At rate of £200.

Huddersfield Royal Infirmary.—Jun. Cas. O. and Res. Anæsthetist. At rate of £150.

Ilford, King George Hospital.—H.S. At rate of £100.

Indian State Railways.—Dist. Med. Officers.

Ipswich, East Suffolk and Ipswich Hospital.—H.S. £120.

Italian Hospital, Queen-square, W.C.—Hon. Asst. Phy.

Keighley Borough Council.—Asst. M.O.H. and Asst. School M.O. £500.

King's College Hospital, Denmark Hill, S.E.—Hon. Radiologist.

Lancaster Royal Infirmary.—Jun. H.S. At rate of £130.

Leicester, Leicestershire and Rutland Mental Hospital, Narborough. Asst. M.O. £350.

Liverpool Port Sanitary Authority.—Port Sanitary Officer. £700.

Llanelly and District Hospital.—H.S. £150.

London Lock Hospital, 91, Dean-street, W.—Res. M.O. to Male Depts. At rate of £175

London University.—Geoffrey Duveen Travelling Studentship. £450.

Margate Royal Sea-Bathing Hospital.—Res. Asst. Med. Supt. £500.

Middlesex County Council.—Dist. M.O.'s and Public Vaccinators. Each £50.

Mile End Hospital, Bancroft-road, E.—Asst. M.O. £250

Nottingham General Hospital.—H.P. At rate of £150.

Oldham Royal Infirmary.—H.S., Cas. O., and H.P. Each at rate of £175.

Paddington Hospital, Harrow-road, W.—Asst. M.O. £250.

Preston and County of Lancaster Royal Infirmary.—H.S. £150.

Queen Mary's Hospital for the East End, E.—Director of Pathology. £750.

Queen's Hospital for Children, Hackney-road, E.—Res. M.O. At rate of £200.

Rotherham Hospital.—Cas. H.S. £150.

Royal Free Hospital, Gray's Inn-road, W.C.—Sen. Res. M.O. £150.

Royal Northern Hospital, Holloway, N.—Clin. Asst. for Med. Out-Patient Dept.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—H.P. At rate of £100.

Sheffield Royal Hospital.—Ophth. H.S. £120.

Southend Municipal Hospital.—Asst. M.O. £275.

South Shields, Ing [illegible] H.S. £150.

St. Bartholomew's I [illegible] M.O. to X Ray Dept.

St. Mary's Hospit [illegible] *hildren, Plaistow, E.*—Clin. Asst. to [illegible]

St. Nicholas Hospit [illegible] Asst. M.O. £250.

St. Peter's Hospital, Vallance-road, E.—Asst. M.O. £250.

Stoke-on-Trent, North Staffordshire Royal Infirmary.—Orthopædic H.S. £150.

Sunderland Municipal Hospital.—Res. Asst. M.O. £200.

Sunderland Royal Infirmary.—H.S. £200.

Swansea County Borough.—Asst. M.O. £500.

Swansea Valley, Adelina Patti Hospital, Craig-y-nos.—H.P. At rate of £100.

University College, W.C.—Bayliss-Starling Memorial Scholarship. £120.

West End Hospital for Nervous Diseases, Gloucester Gate, Regent's Park, N.W.—H.P. At rate of £150.

West London Hospital, Hammersmith-road, W.—Hon. Dermatologist. Also Hon. Asst. Anæsthetist.

Westminster Hospital, Broad-sanctuary, S.W.—H.S. to Spec. Depts. At rate of £104.

Wolverhampton Royal Hospital.—H.S. At rate of £100.

Wolverhampton and Midland Counties Eye Infirmary.—H.S. £150.

The Chie[illegible] announces vacant appointments for [illegible] ons at Clacton-on-Sea, Essex; and [illegible]

The Home Secretary gives notice of a vacancy for a Medical Referee under the Workme[illegible] for the Kirkcaldy Sheriff Court Dis[illegible] of Fife and Kinross. Application [illegible] Private Secretary, Scottish Office, [illegible] W., not later than May 5th.

Births, Marriages, and Deaths

BIRTHS

Elder.—On April 15th, at Welbeck-street, W., the wife of Howard Elder, M.B., Ch.B., South Norwood, S.E., of a daughter.

Evans.—On April 14th, at Devonshire-place, W., the wife of Dr. Horace Evans, of a daughter.

Geldard.—On April 8th, at "Dalmeny," Sheringham, the wife of Dr. Colin Geldard, of a daughter.

Matheson.—On April 8th, at "Eversley," Boxley-road, Maidstone, the wife of Major J. C. M. Matheson, D.S.O., M.B., Ch.B., of a daughter.

Wilson.—On April 11th, at High-street, Linton, Cambs, the wife of Dr. Hugh Mundle Wilson, of a son.

MARRIAGES

Boyle—Scott.—On April 2nd, at St. John's Church, Chorlton-cum-Hardy, Manchester, Major H. A. Boyle, R.A.M.C., to Evelyn Maude, elder daughter of Mr. and Mrs. J. N. Scott, of Chorltonville, Manchester.

[illegible] n April 9th, at the Register Office, [illegible] Burnet Byrom, only son of Mr. and [illegible] of Selby Bridge, I.O.M., and Wigan, [illegible] Joyce Pritchard, only daughter of Mr. and Mrs. Stanger Pritchard, of Cyprus-avenue, Church End, Finchley.

DEATHS

Berry.—On April 15th, at Bramblebury, near Wendover, Frances May Dickinson Berry, M.D., beloved wife of Sir James Berry, F.R.C.S., aged 76.

Brown.—On April 8th, Frederick Nathaniel Brown, L.R.C.P., M.R.C.S., Hale Cottage, Sandbanks-road Parkstone, Dorset.

Keith.—On April 8th, at Comely Bank, Edinburgh, after a short illness, Martha Keith, M.B., Ch.B., D.P.H.

Sanderson.—On April 15th, at Croxteth-grove, Liverpool, William Sanderson, M.B., Ch.B. Edin.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

PETER DE ALCOBASSE

PHYSICIAN TO HENRY IV.

By R. R. JAMES

ON Dec. 14, 1420, Peter de Alcobasse had a grant of denization recorded on the Patent Roll of 8, Henry V, m. 5. It is stated that he was born in Portugal; his grant was under the privy seal and he appears to have paid the sum of £30 into the hanaper [1] for the privilege. Besides this he also appears on the Patent Rolls in the year 1412, Feb. 7, where it is recorded that the King had granted him the prebend of West Thurrock in the Free Chapel of Hastynges; while on Feb. 29, 1412, there is another grant to him, as the King's servant and physician, of the Deanery of Wymburnemynster (Wimborne). Still later in 1412 occurs the mandate to the Dean and Chapter of the King's free chapel of Hastynges to admit and induct the King's physician, Peter Acobasse (*sic*), to the prebend of West Thurrock and to assign to him a stall in the choir and a place in the Chapter. This grant by Henry IV landed poor Peter in trouble in the Court of Chancery in the next reign as will be seen later.

Hutchins, "Hist. of Dorset," vol. III, p. 187, gives: "Peter de Altobasso—or bosco, an Italian, the King's physician, admitted Dean of Wimborne, 29 April, 1412." It is also stated that Peter was Prebendary of Hoxton in St. Paul's, London, in 1420, and of Windsor in 1415; and that he seems to have resigned Wimborne in 1415. The manuscript medical court roll of the late Dr. S. D. Clippingdale, preserved in the library of the Royal College of Surgeons, gives him as Prebendary of St. George's, Windsor, Dec. 21, 1422, vice John Eston, deceased. The reference is to Rymer's "Foedera."

Peter died in 1427. His will, in Latin, would appear to be the earliest medical will preserved in the P.C.C.; there are several points of interest in it, notably the description of "magister in medicinis." The following is the translation :—

> Peter de Alcobascho. (P.C.C., Luffenham, 8.) In the name of God Amen: Thursday next after the Feast of St. Dunstan (i.e., May 19) 1427 I Peter de Alcobascho Master in Medicines of good and sound memory make my testament in this manner. *In primis* I leave my soul to God Almighty, the Blessed Mary and all Saints and my body to be buried in the church of the order of Friar Preachers. I leave to the aforesaid church for my sepulture 20s. I leave to William Denys my servant (*famula*) £20 and one good (*meliore*) piece of silver with a cover, 1 cloak of sanguine (sangwen) furred with marten. I leave to John Wally £10, 1 covered piece, 1 scotch horse and a furred cloak (*toga*). Item I leave to John Cokerman £10, 1 covered piece and a green cloak and a horse called "oldebayard." Item I leave to Ralph Bolde £10, and 1 piece covered and a furred cloak and 1 horse. Item I leave to William Glouceter £10. To Thomas Belle 10 marks 9 shillings. To Thomas lestaville 6 marks and a horse. I leave to Richard my *Capanus* [2] £10 and a horse and a covered piece. To William Barbour 10 marks and an uncovered piece; to Robert de Stabill 6 marks; to Alice Jorge 20s., to Agnes Cornewales 10 marks. To William Sikyltrys, chaplain, 1 mark. To John Carter of Plumsted 2 marks 1d.; to the widow of Richard Clerk my servant 6 marks; to the bedewoman of St. Katherine 9s. To the wife of Robert Notyngham 10 marks. The Residue of all my goods not left in the present testament I give and leave my executors, viz., Thomas Chawcers, Lodovic Johan, Thomas Walsyngham, John Cornewales and Richard Drake, Chaplain, that they do not neglect to dispose in the best manner thay are able for the good of my soul. Proved, 30, June, before Master John Lyndefeld, Commissary.

On the Close Roll of 2, Henry V, May 3 is found mention of the lawsuit of Thomas Feriby, clerk, otherwise priest, against Peter for thrusting him out of his prebend of West Thurrock. It is too long for insertion here; but from Feriby's petition it would appear that he was appointed to the prebend, vacant by the death of John Harmesthorpe, "being a prebend in the King's free chapel of Hastyng in the diocese of Cicestre, and in the gift of William Bourgchier, Knight, in right of Anne his wife, daughter and heir of Eleanor, Duchess of Gloucester." Feriby enjoyed his prebend "peaceably until unlawfully thrust out by the said Peter, by colour of the late King's collation to him . . . at the untrue submission of the said Peter that the same was void, when it was not, and in the King's gift, which it was not." The Sheriff of Essex had notice to make Peter appear in Chancery to show cause why he should not be made to give the prebend back to Feriby. The latter appeared in person and Peter by his attorney, John Corve, who averred that by letters patent dated at Westminster 7, Feb. 13 Henry IV the late King gave him the prebend, being then void and in his gift. The result of the action is not recorded.

I am indebted to Mr. J. Harvey Bloom for the transcript of the will and for the extracts from the Patent and Close Rolls.

---

[1] Hanaper: an office of the Court of Chancery (Trice Martin's Record Interpreter).

[2] A contraction for Capellanus, a chaplain.

RADIOGRAPHY OF LIVING ANATOMY

IN a paper read recently before the Rugby and District Medical Society Dr. J. F. Brailsford, who is radiological demonstrator in living anatomy in the University of Birmingham, demonstrated some of the radiographic appearances of normal structures which have led to serious misinterpretation.

In radiography of the skull the slightest obliquity may result in the dense structure of the base obscuring the normal accessory sinuses on one side, and this may lead to the error of diagnosing that the sinus is occluded. The dense shadow of the petrous portion of the temporal bone may be projected through the plane of the antrum and its straight upper surface may be misinterpreted as a fluid level. An unusual instance of misinterpretation of the normal was as follows :—

> A child with a swelling at the angle of the mandible was X rayed and the radiogram was interpreted as showing a sarcoma. A surgeon was consulted and resection of the involved bone was decided upon. Immediately before the operation the surgeon asked me if I could give him an indication of the boundary of the tumour so that he could gauge what length of bone he must remove from the crest of the ilium to form a graft. It was demonstrated to him that the radiogram showed normal structures only. The shadow of the hyoid bone projected against the mandible had suggested a tumour. A few days later the swelling was explained as an attack of mumps.

In radiography of the thorax it is essential for comparative pictures to be taken in the same phase of respiration. Another source of fallacy arises from the fact that structures in close contact with the film appear denser than the surrounding tissues owing to being screened from secondary radiation.

> A patient was radiographed at a tuberculosis clinic and the diagnosis of bilateral spontaneous pneumothorax made. Examination of the radiograms suggested that further films should be taken, one with reduced pressure against the breasts, and another with the film barely touching the patient. These proved that the abnormal shadows were due to the contact cutting out secondary radiations and consequently reducing the density of the protected part.

In radiography of the alimentary canal it is essential before any opaque medium is introduced to make sure that no abnormal shadows exist which might be obscured by it. In making the gall-bladder visible by substances excreted in the bile and making it denser than the surrounding structures, negative shadows—e.g., of gall-stones—may be simulated by bubbles of gas in the duodenum.

CINERADIOGRAPHY

Owing to the limited time permissible during screening and the limited area which the observer can watch, this method of demonstration is by no means ideal for teaching purposes. What we need, said Dr. Brailsford, is a carefully edited cineradiographic film study of the viscera. This was recognised by Dr. John MacIntyre in 1896, a few months after Röntgen's discovery, and he exhibited a 40-ft. film showing the movements of the bones of a frog's leg to the Glasgow Philosophical Society in that year, and in the *Archives of Skiagraphy* for April, 1897, he described further experiments. In this country Dr. Russell Reynolds had developed indirect cineradiography. More recently Prof. Robert Janker at Bonn had advanced the method to such an extent as to give early hope of using cineradiography in teaching living anatomy.

In the direct method the patient is placed in front of an X ray tube and against a leaded screen containing a window opposite the area to be radiographed. Behind the screen a large film of the necessary size is fixed on rollers and the timing of exposure so devised that at least 16 exposures per second can be made on the rapidly changing surface. From the film obtained reduced films capable of fitting into a cineprojector would have to be made. The large contact films permit a study of the changes in form better than the small films obtained in the indirect method, but the cost is considerable, and while the method may be used for the production of standard teaching films it can hardly come into general use. Simpler devices facilitate a dozen or more exposures within a short time, useful in the examination of stomach and duodenum. A modification of this direct method for recording the movements of the heart was described by Robert Knox in 1925.

In the indirect method a cinephotographic record of the images is produced on the fluorescent screen. The screen image must be sharply defined and there must be no afterglow. By this method Janker has been able to make films little inferior to those obtained by the direct method but at a trifling cost. The intervals between each exposure will determine the rapidity (when shown in the cineprojector) of the movements of the structures examined.

These methods, said Dr. Brailsford, should solve many of the problems of visceral movement. The movements of the heart in diastole and systole during expiration and inspiration could be analysed. The peristalsis of the alimentary canal could be determined with accuracy and the movements of joints in this better than in any other way.

ACUTE SEPSIS IN THROAT AND EAR

IN the *Annales d'otolaryngologie* (1933, No. 12) G. Worms and A. Deburge report the case of a young man in whom an attack of tonsillitis was followed by sudden intense dysphagia and dyspnœa necessitating tracheotomy. There was great œdema of the vestibule of the larynx, the epiglottis, and the aryteno-epiglottidean folds; incision of the latter with curved scissors gave immediate and dramatic relief of the pain. The patient's rapid recovery is ascribed in part to drainage by the tracheotomy incision, from which there was a profuse and foul discharge. To the same journal J. Piquet and P. Coumouma contribute an interesting article on lateral pharyngeal abscess. This is to be distinguished from peritonsillar abscess, in that it is situated externally to the wall of the pharynx and arises in lymph glands about the carotid sheath. It is ordinarily treated by incision through the neck, and any attempt to open it through the mouth is considered very dangerous by reason of the risk of injury to the great vessels: but these authors find that in children the abscess tends to point in the pharynx behind the posterior pillar of the fauces, and may safely be opened in this situation by means of sinus forceps.

D. van Caneghem, of Bruges, also in this issue, reports that he has made a careful investigation into the pressure of the cerebro-spinal fluid in extradural complications of otitis media. In cases of acute mastoiditis, he finds that extradural abscess almost always causes an increase of pressure to above 30 cm. of water, and he believes that extradural abscess should be regarded as probably present in any case which shows this degree of hypertension.

THE LA-TOJA SPA

THE therapeutic claims of the La-Toja Spa were brought to the attention of the medical profession last week by the opening of an installation in connexion with the Spa at Sunderland House, Curzon-street, London, by the Spanish Ambassador. Major P. C. Burton, in welcoming Don Ramón Perez de Ayala, gave reasons for his personal conviction that real medical needs would be met by making the La-Toja treatment available for the relief of rheumatism and allied complaints, and his Excellency in declaring the Spa open expressed his sympathy with the movement as being of therapeutic value while forming a link in the historic friendship between two nations. The La-Toja Spa is near Vigo, and the intention of the London establishment is to make its products available for home treatment on medical advice.

IS PASTEURISATION A COMPLETE SAFEGUARD?

AT a recent sessional meeting of the Royal Sanitary Institute (Jour. R.S.I., April, 1934, p. 486) Mr. Ben Davies said the great thing was to give people confidence in milk so that they should drink more. "With a few ounces of extra daily consumption per capita, the reason for marketing boards and government intervention would disappear." Against the dangers from tuberculosis, abortus fever, and mastitis, he said, we had "a positive and unfailing safeguard" in pasteurisation. Sir W. Dalrymple-Champneys agreed with him that pasteurisation if efficient was a positive and unfailing safeguard; most pasteurisation he had seen was, he added, inefficient. Compulsory pasteurisation not being at present attainable, he thought the best line of immediate advance was that recently contemplated in Manchester—viz., to exclude from the city all but pasteurised milk and that from tubercle-tested herds.

NEW PREPARATIONS

ANTIVIRIN NASAL JELLY (Glaxo Laboratories, 56, Osnaburgh-street, London, N.W.).—The organisms found in the nasopharynx in cases of the common cold are attacked by this preparation. Owing to its viscosity the jelly penetrates the folds of the mucous membrane and brings the appropriate antiviruses into contact with the organisms. Small quantities of Nasal Jelly should be squeezed into the nostrils several times a day, far back enough to bring some of the jelly in contact with the pharyngeal mucous membrane. The treatment should begin, if possible, at the onset of a cold, but is still useful when the condition is advanced.

BURNOL ACRIFLAVINE CREAM (Boots Pure Drug Co., Ltd., Nottingham).—This is a surgical dressing non-toxic, antiseptic, and readily applied; it is absorbent and redressings are easily effected without damage to the healing tissues. The manufacturers claim that its use has given excellent results in the treatment of cuts and grazes; herpes, impetigo, and infective skin conditions; styes and infective conditions of the eyelids; blisters on feet or hands; sunburn; cracked skin and chapped hands. The cream is put up in convenient tubes, and full particulars of application are supplied with each tube.

THE MARMITE FOOD EXTRACT CO. LTD. inform us that as the result of biological tests carried out by a recognised authority, they are now able to state that the vitamin B_1 potency of their product is 840 international units per ounce. This information is of interest in view of recent correspondence in our columns (see THE LANCET, Jan. 13th, p. 101, and Feb. 3rd, p. 261).

ADDRESSES AND ORIGINAL ARTICLES

INTERNATIONAL COÖPERATION IN PUBLIC HEALTH

ITS ACHIEVEMENTS AND PROSPECTS *

BY SIR GEORGE S. BUCHANAN, C.B., M.D., F.R.C.P. Lond.

LECTURE I

IT may be considered to have been the intention of Dr. Gavin Milroy when founding these lectures that they should be a means of enabling a man who had been at work in some particular corner of public health to obtain useful publicity for his subject, and at the same time impose on him the self-discipline of reviewing his experience of that subject in the way which is demanded of one who has the honour of lecturing to the Royal College of Physicians. It seemed to me that I could find such a corner, which would justify my lecturing on it now. After 38 years of official work in the Government health service, I am handing on to my successor the work in applied epidemiology and general hygiene which has been my chief occupation as Senior Medical Officer at the Ministry of Health. That work has come increasingly to be related with, and sometimes even to depend upon, international coöperation, and it is to some aspects of this coöperation that I am now inviting your attention.

Apart from a few questions of port sanitary administration, and from negotiations with foreign countries in connexion with the control over the wholesomeness of imported foods which began with Mr. Burns' Public Health (Regulations as to Food) Act, 1905, I had little personal experience of official international health work before 1914, when the Local Government Board proposed to the Foreign Office that I should be the delegate for Great Britain at the International Public Health Office in Paris. Of this office, which, because French is its official language, is better known as the "Office International d'Hygiène publique," I will have more to say later. Its importance in British eyes was at that time mainly diplomatic. The British delegate was expected to do his best to make our liberal ideas prevail when it came to imposing restrictions on shipping on account of infectious disease, and be ready to give a rational turn, from the point of view of British interests and British hygiene, to the administrations in the Suez Canal, at Constantinople and elsewhere, which controlled the key points by which first cholera, and later plague, might gain access to Europe. In this respect he had to maintain the positions which, since the cholera pandemics of the middle of last century and the later Hamburg outbreak of 1892, the medical advisers of the British Government, notably Netten Radcliffe and Thorne-Thorne, had successfully fought for and secured. But he was not expected, nor at that time would it have appealed to him, to make the international office a means by which the delegates of the several countries there represented (and at that time many important countries remained outside) could concert together common official action for the prevention of disease or for the promotion of public health, outside these narrow limits. Within them our Government had been admirably served, first by my colleague Dr. Theodore Thomson, whose untimely death was an incalculable loss to State medicine in England, and then for a short period by the late Dr. R. Johnstone, who had seen through the International Sanitary Convention of 1912. I need not speculate on what I might have myself made of the position at that time; the war years supervened, during which most of the functions of the Paris Office were in abeyance. After 1918 the situation was altered. The war itself had shown the advantages, as between the allied armies and countries, of pooling information about disease prevalence and prevention—or to put the matter inversely, the drawbacks of inadequate coöperation. The great forces of the Red Cross, with their international outlook, could hardly have been demobilised without thought being given to the extension of their universality and catholicity to the post-war world for which we were then groping. The League of Nations was being formed, and the ideals of its founders for obtaining union between nations extended to its providing, or even forcing on, international coöperation in technical and humanitarian questions. Moreover, in many countries, by the formation of separate Ministries of Health or otherwise, public health was receiving a higher official status, and was undertaking new work calling for international contacts. Finally a common peril, the threatened spread of epidemic typhus from Russia through Poland to the west of Europe in 1918 to 1920, made an immediate call for coöperation.

The years 1919–21 thus were the occasion of many conferences and discussions with the object of securing, if possible, a single mechanism, dependent on the League of Nations, by which health questions affecting Governments could be dealt with internationally, and of settling at the same time what particular questions were ready for the proposed machine. Those who are interested in the phase in which the matter stood in 1921 may be referred to an address which I gave to the Society of Medical Officers of Health in February of that year (THE LANCET, 1921, i., 415) on International Organisation and Public Health. It is true that this address led up to the description of the mechanism for the purpose which had been adopted by the first Assembly of the League in December, 1920, but did not materialise—the chief reason being that certain important Governments objected to the Paris Office being placed under the direction of the League of Nations. But they will also find a number of health matters then catalogued as requiring joint Government action which *have* since materialised and have now been adequately treated by the actual international machinery which was ultimately arranged, and has been in operation during the last 13 years.

A few landmarks have here to be noted for reference. The Secretary-General, personally and through Dame Rachel Crowdy, D.B.E., who was then charged with this subject at Geneva, and afterwards through the late Dr. E. J. Steegmann, acting Medical Secretary, took steps to consult responsible officers in the public health services of several countries, including the United States, while several members of the Council of the League, particularly M. Léon Bourgeois and Lord Balfour, were active in pressing for immediate attention to the question. The then Director (M. Cazotte) and Assistant Director (Dr. Pottevin) of the Office International d'Hygiène publique, and M. Velghe, the President of its Permanent Committee, were naturally brought into these consultations, as was the League of Red Cross Societies through its General Medical Director (Colonel R. P. Strong), and the International Labour Office, in respect of its industrial medical section, through Mr. H. B. Butler. By July, 1919, the position was ripe for an informal conference, held in London at the Ministry of Health, over which its then Parliamentary Secretary, the present Lord Astor, presided. This conference was then invited by the Council of the League of Nations to reassemble as a formal conference, adding to its members a small number of international health experts. This formal conference met in London in April, 1920. Based on its work a draft constitution of a public health organ of the League was submitted to a meeting of the Council at San Sebastian in August, 1920, which I attended as technical adviser to Lord Balfour. There emerged the constitution accepted, with a few modifications, by the First Assembly on Dec. 10th, 1920, and recorded in its minutes. The decision of the Assembly, to become effective, required the assent of the Governments parties to the Rome Convention, 1907, and, as stated above, it was afterwards found that this assent could not be obtained. The First Assembly plan, stated briefly, was to recognise the existing state of things by continuing the Office International with its existing personnel and offices at Paris, which would be the normal place for meetings, but to transfer much of its executive work and all new undertakings to a medical secretariat at Geneva. The latter was to be directed by a small technical executive "Standing Committee," which in its turn was to get its policy from and be responsible to a general Health Council. The last-named would have consisted of the delegates to the Permanent Committee of the Office International with the addition of technical delegates from various countries not then participating in the work of the Office. The general Health Council—i.e., the enlarged Permanent Committee of the Office—the Executive "Standing" Committee, and the Geneva medical staff were for their particular business to be in a mutual relation comparable to that of the Assembly, Council, and Secretary-General of the League itself.

---

* The Milroy Lectures delivered before the Royal College of Physicians of London on Feb. 27th and March 1st, 1934, with a few subsequent additions of detail. Lectures II. and III. will appear in coming issues.

The point of this scheme which is most noteworthy in view of subsequent developments was that it made the whole health work of the League, including that of the Paris Office which would have been placed under the direction of the League, ultimately dependent on a general assembly consisting of technical delegates all nominated officially to that position by their respective Governments.

The catalogue which I made in my 1921 address of the principal subjects which were then being brought up as requiring international action showed the chief to have been the revision of the international sanitary conventions, the establishment of a new system by which public health administrations could rapidly exchange intelligence about the occurrence of infectious diseases, provision at the principal seaports of agreed practices for treating venereal diseases in the mercantile marine and for the destruction of rats, unification of vital statistics, and organised relief work for major epidemics, such as the European typhus above referred to.

Looking back at that catalogue, I gladly recognise its incompleteness; many more questions than were then foreseen have during this period received effective attention from the International Health Office at Paris or the League of Nations Health Organisation at Geneva. It may be regretted that the formal combination of both these organisations under the League was not established as intended in December, 1920; but it may be contended on the other hand that several events have shown the advantage of the decision that they should function separately under a specially elaborated system of liaison, and one which can at any time be reconsidered if circumstances call for it.

The main lines of this liaison were established at a conference in Paris in May, 1923, of a "Mixed Commission" (members of the provisional Health Committee of the League, in function August, 1921, to June, 1923, and of the Permanent Committee of the Paris Office), convened at the request of the Council of the League and presided over by the late Dr. Alexander Granville, C.M.G., President of the Sanitary Maritime and Quarantine Board of Egypt. The constitution of the Health Organisation of the League, as drawn up by this Commission, was formally accepted by the Permanent Committee of the Paris Office and the Council and Assembly of the League, and it is embodied, along with various subsequent resolutions of the Council, in the present organic statutes of the Organisation. In addition to a medical staff of the Secretariat, appointed by the Secretary-General, the "Health Organisation" comprises a Health Committee, whose members are appointed triennially and in their individual capacity. This committee is appointed by the Council, which, however, accepts nominations of nine of the members from the Permanent Committee of the Paris Office. The Permanent Committee of the Paris Office is by this instrument also made available for consultation by the League; and its members have the right to receive the League's medical publications and to advise as to the annual programme of work at Geneva. In practice the Medical Director of the League attends or is represented at the sessions at Paris and the Director of the Office International d'Hygiène publique those of the Health Organisation at Geneva. In 1926 other links were created by the use of the Singapore Bureau (to which I refer below), as a regional bureau of the Paris Office for information about epidemics in the Far East, and by an arrangement whereby a weekly statement about infectious diseases, supplied by Governments to the Paris Office under the terms of the International Sanitary Convention, 1926, is transmitted to Geneva and receives general publicity in the "Weekly Epidemiological Records" issued by the Health Organisation.

A consideration of much greater interest is what has been accomplished since we started on the broader road, after the war, both at Paris and at Geneva, and what encouragement we have to do more work on the same lines in future. It is with this that these lectures are mainly concerned.

As in 1921, I am anxious not to seem to claim too much either for the work on which these official international offices are engaged or for the work which they ought to undertake in future. Any suggestion that medicine, always among the most international of the learned professions, should henceforth first look to the League of Nations or any other inter-Governmental office in order to maintain its proud tradition of internationalism would indeed be retrograde. Lister, Pasteur, and Koch were all good patriotic nationals, but it goes without saying that their work was done for and taken by the whole world. In ordinary medical connexions their nationalities trouble us as little as that of the great musical composers. Voluntary and unfettered association with our colleagues in foreign countries and the British Commonwealth of Nations is vital for us. And when medicine and hygiene in the United Kingdom tend to become too insular—as they sometimes do—it is fortunate that we have the publishers and the medical journals to put us in the right way. They have, for our good, an international tradition, all the stronger because they are not officially guided or, in the jargon of to-day, not rationalised. And it is the same thing with the many congresses and conferences on medical subjects which are organised year after year by the profession itself. We all affect to regard them as a trial, but we go to them and we benefit. Governments may assist these conferences—one may mention specially those of France, Spain, Belgium, and Holland as always active in this conexion—and Government aid is a great help to their rganisers. But it is assistance with the amenities, nd in no sense implies interference with the organisa-ion, objects, or conclusions of the conference. At andom, and taking European conferences alone, I ave notes of 24 international medical meetings in 932, and 23 in 1933 down to November. They range rom small gatherings with a closely guarded member-hip, such as the Congress on Urology held in London ast year, to larger meetings like the Journées Médicales at Brussels, or the recent Cancer Congress t Madrid, which have lay as well as medical elements. This is in Europe, but we must also take account of imilar international meetings in the Americas and Congresses such as those of the Far Eastern Association of Tropical Medicines, which have so wide an influence n spreading knowledge and promoting research all through the East. In fact, if physicians, when they hear international medical work spoken of, think first of their personal association with particular gatherings of this voluntary kind, and of contacts and friendships then established with colleagues from overseas, it would be natural and fitting. Nothing could replace them.

Research workers again, as well as those concerned with certain aspects of public health administration and education, will very properly associate international medical work first and foremost with that great international body, the Rockefeller Foundation.

THE ROCKEFELLER FOUNDATION

If the Rockefeller Foundation is not strictly speaking a body designed to secure international coöperation of the kind with which I am here dealing, it is none the less an international body in the sense that it is one of its principles to distribute its work among all the nations. It is difficult to over-estimate our debt to this institution, and to the idea of the family which founded it, that some of its money profits drawn from every part of the globe should be returned so as to "promote the well-being of mankind throughout the world."

The Foundation, which as at present organised has its headquarters in New York with important branch offices, for example, at Paris and Peiping, succeeded in 1928 the "International Health Board" which had been formed in 1913, and itself arose out of the Rockefeller Sanitary Commission in hookworm in the United States which began in 1909. On the health and medical side it has two main divisions—for international work and for work on the medical sciences respectively. The latter is the more recent development, on which chief emphasis was laid in making the changes of 1928, and itself represents a stage in evolution. Beginning with giving assistance in various ways to particular practical measures of public health in suitable areas and the local demonstration of what can be done locally against particular diseases, the Foundation soon came to extend its efforts to the advancement of medical and public health education. From this it has been led to include in its programme work for the direct advancement of the medical sciences themselves and to methods of subsidising research in a way which Governments are rarely disposed to do. All these activities continue side by side, and their universal character has been maintained. The annual reports of the Foundation give abundant evidence of the large scale on which the sums have been disbursed and the wideness of the geographical distribution of the work, while, for an outline of the Foundation policy in these matters readers should consult "The Rockefeller Foundation: a Review for 1928," by Dr. George E. Vincent, published in the following year.

If reminders of the result of the work in the British Empire were necessary, we have only in London to think of the building of the London School of Hygiene and Tropical Medicine, opened in 1929, or the clinical research professorship at University College, or the assistance given to other medical schools in Oxford, Cambridge, and Edinburgh. The Dominions and India (notably by the assistance given to the All-India Institute of Hygiene and Public Health at Calcutta) furnish plenty of other examples. Teachers and investigators from the British Empire, moreover, are included among the 500 individuals from 48 countries to whom the Foundation annually gives fellowships for study in countries other than their own; while it is common knowledge that many British colonies and possessions are now actively benefiting by research work such as that conducted at the New York and other laboratories into the virus of yellow fever. If I was writing of France, Italy, or China, to take three countries at random, the examples to give would be no less striking.

This is not the occasion to discuss the many different methods by which the Foundation proceeds in the execution of the different branches of its health and medical policy, though its practice of limiting its grants to established bodies, government services, or institutions must be mentioned. In general, the Rockefeller tradition is one of freedom from political ends, international as much as national. It is no part of its programme to get together official conferences of experts from different countries, or to suggest health policies to Governments, in the way which is done by the organisations at Geneva and Paris. Nevertheless, as much of its health work is done through the Government health services, and as its activities leave hardly any region on the map of the world untouched, its indirect influence in securing good international relationship between medical workers is very great.

It is impossible also to consider international organisation in medicine without looking back to the battle of Solferino, to Henri Dunant, and so to the handful of Geneva citizens through whom the International Red Cross Committee was established in 1864. The whole Red Cross movement dates from then and the several international Red Cross Conventions have followed. Memories of Red Cross work in time of war and of the international obligations attaching to that symbol are still with all of us, while since the war there has been a notable development of Red Cross peace-time work on international lines.

THE RED CROSS AND LEAGUE OF RED CROSS SOCIETIES

The International Red Cross Committee continues its work at Geneva, and deals with the fundamental principles of the Red Cross and with the International Conventions from which it derives authority. It is a separate and independent part of the International Red Cross organisation, as defined by statutes adopted at the Thirteenth International Red Cross Conference at the Hague in 1928. Side by side with it now in the International Red Cross Organisation is the peace-time branch of the Red Cross, represented by the League of Red Cross Societies—with the creation of which, in May, 1919, the name of the late Mr. Henry P. Davison is so honourably associated. The membership of the League is restricted to participating national Red Cross Societies, now 58 in number; it has a representative Board of Governors, a small Executive Committee, meeting twice annually, and a Secretary-General, now Dr. René Sand, with headquarter offices in Paris. At present the League's principal peace work, in addition to coördination, lies with relief in times of disaster, popular health education, and the training of nurses. The League of Red Cross Societies was also instrumental in the establishment of the International Hospitals Association, and has taken special interest in matters affecting the welfare of the merchant seaman.

Health Work of the League of Nations

Where then, on lines not covered by the organisations I have described, has the League of Nations come into the picture of international coöperation in health matters? Obviously the Governments which the League represents have no particular reason to compete, or deal otherwise than by friendly unofficial liaison, with international medical congresses, with the Rockefeller Foundation or the Red Cross work. Moreover, it was settled in 1921 that the International

Health Office in Paris should continue, independently of the League, to carry on the functions of an organ which had been established under formal diplomatic agreement (1907). This was an existing body dependent on a committee which consists of technical representatives of Governments on public health questions, available and capable, within the limits of its finance, for taking up the study or regulation of any international questions affecting Government health services.

When one seeks to explain how the Health Organisation of the League, while escaping from most of the dangers of overlapping, supplanting, or superseding the work of other organisations which should be allowed to develop on their own lines, has yet succeeded in making a position for itself to which the world is ready to pay tribute, one comes at once to emphasise the following considerations :—

(1) The wide terms of its charter. By Article 23 (f) of the Covenant the States members of the League have undertaken the duty in general terms to "endeavour to take steps in matters of international concern for the prevention and control of disease."

(2) The decision taken at the earlier Assemblies, and since maintained, that a substantial sum, in recent years stabilised in the region of 1 million Swiss francs (£40,000 at the old exchange rate ; the Swiss currency remains on the gold standard), with a generous annual addition from the Rockefeller Foundation, should be allotted each year to the organisation, enabling it to be provided with a considerable medical staff under a Medical Director, who holds one of the highest positions in the Secretariat.

(3) The great post-war extension in State organisation of, or State control over, medical and public health work in almost every country in the world, which has resulted in new demands for aid with the experience of other countries. The official collaboration required is now not only the prevention of particular exotic diseases but something very much wider.

And to these I would add a fourth—namely, an active opportunism, ready to seize upon projects which have not been undertaken before from an international standpoint, to try them out, and gain experience from success or failure. In the health work done at Geneva during its first 13 years attempts to systematise and define what should or should not be done have, fortunately, not been very fruitful. The impulse has come sometimes from the administrator, sometimes from the laboratory, sometimes from the insistence of some particular Government or delegate, and sometimes again, has been essentially due to some political factor which has made it desirable in the interests of the League to show its flag and inscribe international health upon it. Dr. L. Rajchman, who has been the League's Medical Director since 1920, and whose ability is so universally recognised, has never failed to capture or provoke these impulses at a suitable moment, and to make his organisation respond to them. As a result certain lines of activity, arbitrary if you like, have become recognised as a fixed part of the Geneva work ; other undertakings have been completed, or it may be dropped or put into cold storage. In other words, it is a young, living, and still growing organism, seeking to learn and do its best to fulfil and do credit to the article of the Covenant which I have quoted.

For proof it is only necessary to look through the large number of reports and publications of the Health Organisation and observe the extensive ground which they have covered. A complete collection, I believe, exists in the library of the College and in one or two other important medical libraries in this country. Since 1931 their systematic collection has been greatly facilitated by putting the reports of Commissions and the expert studies into a Quarterly Bulletin. By taking this Bulletin, along with the records of the sessions of the Health Committee and of the Second Committee of the Assembly (which deals with the Technical Organisations of the League) and a few specially printed reports, such as that of the Singapore Bureau, the Geneva output can be appreciated as a whole.

It is not too easy to classify these activities and select examples, but I may begin with some instances of work in which the League has been able to render a definite service to medicine, and then go on to other matters in which the League has found advantage in using medical and public health knowledge to further its own objects of promoting fellowship between nations.

BIOLOGICAL STANDARDS COMMISSION

Our Therapeutic Substances Act is as recent as 1925, and it was only when that Act, and the regulations made under it, came into operation that we were in a position to exercise effective control over the purity of potency of therapeutic substances which cannot adequately be tested by chemical means. We now accept this control, both for the home product and for products coming from overseas, as part of the natural order of things, and are familiar with the exact and scientific methods by which the regulations have been prepared and are enforced through the National Institute for Medical Research and the central public health departments. But the part played by the international conferences on these questions can hardly be over-estimated. Some years before the enactment of our own legislation it had been evident that the difficulties which we were encountering were also weighing heavily on other countries. The uncertainties about the measure of potency of antitoxic sera, notably those for diphtheria and tetanus, received immediate attention after the war ; as also did the need for a better understanding of the tests to be applied to salvarsan and analogous substances. National difficulties in deciding on the admission of these remedies from foreign laboratories and doubts about the sufficiency and efficiency of purely national methods of control, found expression at the Paris Office in 1919 and 1920. It then became clear that it was only by the close association of expert workers in the principal laboratories concerned that any satisfactory agreement could be arrived at either as to tests to be applied or as to the standard substances which should be maintained in particular laboratories for international reference.

Here it was at once realised was a promising ground for the new International Health Organisation of the League, which had sufficient funds at its disposal to organise the necessary conferences and coördinate work in different laboratories. The first trial of this method, especially in relation to the antitoxins I have mentioned, was initiated by a conference in London in 1921, followed by another in Paris in November, 1922. Meanwhile, on the side of therapeutic substances requiring biological tests, another conference was prepared for and held in Edinburgh in July, 1923, when a beginning was made in obtaining a common basis for the measurement of composition, potency, and purity of such substances as thyroid and pituitary extracts, ergot, and digitalis, and another beginning with insulin. Other conferences have since followed at Geneva (1925), Frankfurt (1928), and London (1931) as well as meetings of groups of workers on special subjects at Copenhagen and elsewhere in between sessions. The report of the London conference of 1931[1] gives a useful review of the whole of the work completed to that date, and the matters then left outstanding, with some new questions like the standardisation of sex hormones, are to be considered at further conferences during the present year. All this varied work of standards has throughout been planned and kept going by a small body of experts which now constitute the "Permanent Commission on Biological Standardisation." Dr. Madsen is the chairman of this Commission, which includes Sir Henry Dale, Prof. Kolle, Dr. McCoy, Prof. Bordet, and Prof. Louis Martin. A collateral conference on the standardisation of vitamins was held at the same time under the chairmanship of Prof. Mellanby.

The Commission on Biological Standardisation thus now occupies a key position in securing reasonable and scientific control over the quality of these essential modern remedies. The British Pharmacopœia, in 1932, in dealing with substances only assayed by biological methods, now includes those alone for which the Permanent Commission on Biological Standardisation has recommended a definite standard of reference, and accepts the principle that no biological method of assay is satisfactory which does not depend on a comparison between the sample to be tested and the standard preparation. The work of providing and distributing samples of these standard preparations in this country is undertaken by the National Institute for Medical Research, and that Institute acts in several cases as the depository of the international standard itself, on behalf of the International Commission. The chief standard vitamins are thus maintained there. Other international standards are kept on behalf of the Commission at designated laboratories at Copenhagen, Washington, Frankfurt, Batavia, and elsewhere.

The spade work and the practical decisions on these different matters fall, of course, on the experts and laboratory workers themselves in their own countries. The part played by the Geneva organisation is the essential one of maintaining continuity and providing the necessary centre on which national results can be focused. By now the medical staff at Geneva has gained much experience in the arrangement of these conferences; in fact each conference brings with it a new experience, which facilitates the progress of a work which must necessarily be continuous and requires a high degree of organisation at headquarters.

INTERNATIONAL STUDY OF "HEROIC" REMEDIES

This experience indeed has lately led to the revival of a similar project—namely, to entrust to the Health Organisation of the League of Nations the duty of arranging for continued expert study of heroic remedies by pharmacologists and chemists. The International Conference on the Control of Heroic Remedies, held in Brussels in 1925, it will be remembered, fixed the quantities of particular potent drugs—morphine, strychnine, cocaine, &c.—in the standard products which find a place in the different national pharmacopœias. There can, however, be no finality either in the quantities and proportions of these substances required in medicine or in the tests applied for their determination; while the need for including new preparations has always to be borne in mind. The matter has still to be considered by the Health Committee of the League, but experience of the Permanent Commission on Biological Standardisation can without doubt be effectively urged in support of the proposal.

WORK ON MALARIA

Malaria was among the first international health questions which the League of Nations was asked to include under the terms of Article 23 of the Covenant requiring it "to endeavour to take steps in matters of international concern for the prevention and control of disease." As the British Empire, with its vast tropical territories in Africa, India, and the Far East, is more concerned with malaria than is any other group of nations in the world, it was appropriate that this country should take the initiative in requesting the League to consider it. As British representative on the League's Health Committee, on the advice of my colleague, Colonel S. P. James, I brought the subject to notice in May, 1923, in connexion with the remarkable epidemic extension of the disease which was occurring in South Eastern Europe. This resulted in the appointment of the Malaria Commission of the League under the presidency of the Italian member of the Health Committee, Dr. Lutrario. That Commission constitutes a body of experts who are well qualified to act as a central agency to which the health administrations of different countries can submit their malaria problems for information and advice, and it has made it its business to collect and analyse information from all parts of the world on the incidence, epidemiology, prevention and control of the disease. Though not in a position to undertake research work itself, it has also stimulated and coördinated national research. At an early stage "study tours" of malarious countries were made by expert members or groups of members of the Commission. During these tours information furnished by local workers and observations made on the spot were examined and discussed by malariologists belonging to varied schools of antimalarial practice and opinion. Holland, Denmark, Jugo-Slavia, Czechoslovakia, Greece, Bulgaria, Rumania, Russia, Italy, Spain, Corsica, Palestine, the United States, and India are some of the countries in which these tours of inquiry have been made.

I have spoken of the opportunism which has determined our lines of work at Geneva; and this certainly was an example of an opportunity seized at the right moment. In the years immediately following the war there were countries, like our own or the Netherlands, in which the former prevalence of malaria had been almost forgotten, but which were in the new position of receiving human carriers in abundance from the malarious war areas, while they still had no lack of indigenous anophelenes to provide the necessary insect carrier. Other countries in Europe seemed, as a result of war and post-war changes, to present the difficult problem of an increased general susceptibility of their population on the one hand, and the introduction of new and virulent strains of the malaria parasite on the other. Then also, there were countries, including new colonies or possessions, which were beginning to organise or reorganise their public health services, and finding how malaria dominated the position. However clearly it seemed to have been proved that particular areas, like the Panama Canal zone, could be freed from indigenous malaria by the systematic and thorough attack on the insect carrier through the suppression of its breeding places, and by protection against the adult anopheline, to advocate a general application of this radical measure to the malarious populations of the world—to the great river deltas, fens and marsh countries, let alone the malarious hill countries—was a mere counsel of despair. No health authority could be given the staff to do it, no administration could for a moment contemplate the expense, while half-measures on this basis were useless. It was the time, therefore, in the search for practical alternatives and practical policies, to take up wider views of malaria and its epidemiology. Why had malaria practically disappeared from Northern Europe before any of the knowledge we had from Manson and Ross? What is the extent of the natural protection conferred by attacks of malaria in infancy, and what part does natural or acquired immunity play in a malarious district? How is it that more intensive agriculture, the Italian "bonifications," and other measures for increasing the general welfare and prosperity of the people have by themselves done so much to reduce malaria? These and a host of other questions, like the prophylactic use of quinine, were going through an agitated period; controversies had multiplied, and rigid doctrines were being set one against the other. It was a service then to many countries and Governments to bring their exponents together, not merely to hammer out a least common measure of agreement or a formula, but to confront them with the problems on the spot, under differential conditions, and then see what common advice they could arrive at. It was only when this had been done in a sufficient number of instances that the Commission set itself to the general review of the principles and methods of malaria prevention published in 1927: "Principles and Methods of Antimalarial Measures in Europe" (C.H./Malaria/73), a publication which has proved invaluable by showing the many ways in which malaria can be effectively controlled, and the conditions which should determine their choice in a particular case.

---

[1] League Publication III.: Health, 1931, iii., 10.

The question whether pure quinine is essential, or is only an expensive medical habit which could be abandoned for other cinchona preparations or mixtures was answered in favour of the latter. The Malaria Commission of the League has responsibility for *Totaquina*, a cheaper product in which all the alkaloids in cinchona bark are present, but standardised to 70 per cent. of crystallisable alkaloids, of which not less than 15 per cent. must be quinine. Totaquina appears in the last edition of the British Pharmacopœia and is now being used for the treatment of malaria in several countries of Europe and the Far East.

And while this work was proceeding two events of outstanding importance in the history of malaria research occurred. The first was the discovery in Germany of synthetic drugs which promise to be more effective antimalarial remedies than quinine. The second was the application in England of the clinical practice of "malariatherapy" and the study of malaria in the human subject under controlled laboratory conditions. These events quickly led to great advances in knowledge and to a radical change of thought and opinion on many aspects of the disease including methods of treatment, control, and prevention. The Malaria Commission of the League had taken no part in those events, but the Commission was there; it had proved its ability in other fields, and it was natural to seek to use it as an organisation through which the new knowledge could be sifted out and brought authoritatively to the notice of all malarious countries. Workers in the several countries where the new researches were being conducted willingly agreed to collaborate in the preparation of an agreed "international" report, with the result that a comprehensive article containing the most recent information available was published in the League's Quarterly Bulletin for June, 1933, under the title "The Therapeutics of Malaria." This comprehensive account of the subject is evidently serving a useful purpose, for it has had to be reprinted and is said to be a "best seller" among League publications. It has, at the right time, met a real want on the part of public health officers in many countries.

Mention should be made of one other matter in which the international machinery of the League has proved useful in dealing with malaria—namely, by aiding the establishment of different centres of courses of study for junior medical officers, of any nationality, who are about to undertake antimalarial work in the public health departments of malarious countries.

"APPRAISAL" IN OTHER DISEASES

The system of "appraising" data from different countries has been applied to certain other disease problems. For some of these the Secretariat has been so fortunate as to obtain the services of some one man to give the time and trouble necessary to an elaborate survey of material obtained from many countries. Dr. McKendrick's reports on the results of antirabic treatment in different parts of the world is a case in point, as also are the long and careful studies made by Dr. E. Burnet resulting in his monographs on international practice for the control of leprosy and tuberculosis. In other instances a system of "expert committees" has been followed, each with a rapporteur to do the main work. Reports on infant welfare and maternal mortality have been done in this way. In this connexion the work done, or now in hand, in relation to syphilis and cancer may be mentioned in a little detail.

WORK ON SYPHILIS

I refer below to the action initiated at the International Office of Public Health at Paris in 1920 to secure the agreement which has since been made between maritime countries for the free treatment of venereal diseases at the principal seaports. Part of this scheme was that the merchant seaman, on visiting a seaport clinic, should be given a personal card with entries, intelligible at the clinics of other ports in other countries, showing his diagnosis and the treatment he had received. Naturally, in the case of syphilis, this meant entering the results of his serological tests. At once, however, questions arose about the notation to be employed for the results of the Wassermann test and about the significance of the test when done in different ways. The same questions came up at the conference on the welfare of the Mercantile Marine at Copenhagen in 1921, when the practical application of the proposed international agreement was being considered. These were difficulties universally felt, going much further than the sailor at the port clinic. A particular clinician who was used to a particular serological notation employed by himself or by the pathologist with whom he habitually worked, could, of course, use the +, −, or ± signs in any convenient way without troubling about the actual or relative value of these signs; and he could multiply, vary, or qualify his symbols as he chose. But what was another man, out of touch with him, to make of them? Then, too, came the question of the influence of minutiæ of laboratory practice on the results of the Wassermann test, while, as the study of the subject w[illegible] and drawbacks of substituting [illegible] Georgi, Sigma, Meinicke, M.T.R.) for Wassermann methods could not be ignored. To realise the practical importance of a general understanding on all these matters one had only to consider how the welfare and the treatment of all the many cases reported to be on the serological borderline were being quite arbitrarily governed by the tester, his methods, and his notation.

These matters were taken up at successive expert conferences arranged for this purpose by the Health Section of the League in London in 1921, in Paris in 1922, and in Copenhagen in 1923. The last of these was a working laboratory conference lasting for some weeks at which representatives of eight laboratories in Austria, Belgium, Denmark, France, Germany, and Great Britain met together and tested the same 500 specimens of serum by a series of different serological tests, each in the way preferred by the experimenter. The findings of this conference as to essential details of the tests are well known, since the standard notation for reporting results which it recommended is now in general use. In 1928 the subject received further attention at a second laboratory conference in Copenhagen, on an even larger scale, cerebrospinal fluids as well as serums being tested; there has also been another important laboratory conference of the same kind in South America—in Montevideo in 1930. The whole ground covered by these conferences was reviewed as recently as October, 1932, in a report by Jadassohn, Gougerot, and Harrison, drafted by Dr. Moerch, of Copenhagen, and published in Vol. 1, No. 4, of the Quarterly Bulletin of the Health Organisation of the League. The rules therein recommended have since received a wide acceptance. It is beyond question that these laboratory conferences have been of great value in promoting improvements in serum tests for syphilis and helped to a more judicious use of them in practice all over the world. For this result special recognition should be given to the President of the Health Committee, Dr. Madsen, whose laboratory at Copenhagen has been designated by that committee as the central laboratory for reference in these matters, and to the indefatigable efforts of Colonel L. W. Harrison in this country, from the beginning of the inquiry, to maintain it at the highest level of precision in its work and exactness in its conclusions.

As with malaria, so in this case one piece of international expert coöperation led to another. This close association of syphilologists for the purpose of dealing with serum tests which are vital for modern treatment could hardly escape leading to mutual consideration of modern treatment itself. There is the greatest diversity of opinion on the amount of different remedies necessary to eradicate syphilis; treatment suffers, and may even be discredited, by these divergencies. Could not something be done by pooling knowledge? The Health Committee was persuaded to accept the challenge, and collect from a large number of countries individual case records made out on a standard plan showing stage of the disease, amount of treatment, and serum reactions before and after treatment. It sounds—indeed when first proposed it was thought to be—a fairly simple thing to do. In point of fact, the difficulties have proved considerable. With the best will in the world, busy clinicians and institutes do not find it easy to maintain special books and records over a long period; they must be fully satisfied that the analysis which results from combining their work with others will be worth having; and they are well aware that magnitude of data does not necessarily compensate for inaccuracy or error. Colonel Harrison by his energy obtained over 3000 individual records from clinics in England and Wales, and by 1932 he had seen to their preliminary examination and transmitted them to the centre chosen for global analysis under the advice of the expert Subcommittee of which he is a member. Other countries have also responded on a large scale, and it is estimated that in all something like 30,000 case records will have been sorted out for consideration by the Subcommittee when it meets this year.

RADIOGRAPHIC DIAGNOSIS OF GASTRIC AND DUODENAL ULCERATION

By G. R. Mather Cordiner, M.B. St. And., D.M.R.E.
ASSISTANT RADIOLOGIST, ST. GEORGE'S HOSPITAL; AND

G. T. Calthrop, M.D. Camb., D.M.R.E.
RADIOLOGIST, THE RADIUM INSTITUTE; ASSISTANT RADIOLOGIST, THE DREADNOUGHT HOSPITAL, LONDON

(WITH ILLUSTRATIONS ON SPECIAL PLATE)

Using the opaque meal examination as it is generally carried out, it is often difficult or impossible to demonstrate gastric or duodenal ulceration on the radiogram. To H. H. Berg is due the credit for elaborating a technique by which one can show conclusively not only the anatomical condition of an ulcer but also in most cases the consecutive changes of ulceration.

In 1913 Forssell[1] published his researches into the physiology and pathology of the mucous membrane of the gastro-intestinal tract, and it is upon this basis that the technique has developed. In 1921 Akerlund[2] enunciated the principle of screen control in the radiography of the duodenum, and in 1927 amplified his method by the addition of compression. In 1925 Berg[3] applied the work of Forssell and Akerlund to a detailed study of the pathological gastric and duodenal mucous membrane, and by developing and perfecting the "aimed dosed compression" exposure technique has raised the radiological diagnosis of ulcer to a degree of accuracy and refinement hitherto unobtainable. Among others, his former pupil Albrecht[4] has amply proved the great value of the method.

THE METHOD

The "aimed dosed compression" exposure method is an attempt to demonstrate radiographically the mucous membrane of the stomach and duodenum after it has been coated with as thin a layer as possible of opaque meal. Varying degrees of compression—"dosed compression"—are applied over the stomach and duodenum to show the details of the mucous membrane to the best advantage, and at any particular moment a permanent record of the screen image is obtained by the immediate exposure of a film—"aimed exposure."

In order to carry out the method certain refinements in apparatus are necessary. A tilting couch is essential to allow of the examination of the patient in any position between the Trendelenburg and the erect. Some means of applying dosed compression must be available, and a small metal cylinder, 4 in. in diameter, with an aluminium cap, is used for compression over any particular area. It must be possible to change-over from screening to radiography in a fraction of a second.

After the preliminary examination of the thorax and abdomen the patient takes a small mouthful of the opaque meal. The examination is best begun with the patient recumbent. The progress of the meal down the œsophagus is watched and any apparent departure from the normal confirmed by aimed exposures. The entry of the meal into the stomach is carefully observed, and by tilting and turning the patient the fundus is thoroughly examined.

By bringing the couch gradually towards the erect position, the meal is allowed to trickle slowly down the stomach, the palpating hand guiding and distributing it over the mucosal surface. The stomach and duodenum are systematically explored under dosed compression. On the least suspicion of abnormality aimed exposures are made. It is only after the examiner has thoroughly satisfied himself both by screen examination and by radiograms as to the anatomical condition of the stomach and duodenum that the patient is allowed to drink the full meal. The function of the stomach is then investigated by the ordinary method.

No fixed routine can be laid down which will meet the needs of every case. A highly cultivated screening technique is essential, and it is obvious that only those who are experienced in screening and who have the necessary apparatus can make the most of Berg's aimed dosed compression exposure method.

THE MUCOUS MEMBRANE

For the proper appreciation of the method a thorough knowledge of the radiographic appearances of the normal gastric and duodenal mucous membrane is required.

If a small amount of opaque meal is taken into the fasting stomach and spread over its surface, radiographic examination shows that the mucous membrane is thrown into folds. Although great variations occur in the course of the folds, certain constantly recurring configurations, which are more or less typical, can be distinguished. The radiographic picture of the gastric mucous membrane bears a very close resemblance to the naked-eye appearance of the now classical anatomical specimen of Elze, a specimen obtained shortly after death.

From the fundus, where they are arranged as a complicated network, the folds run longitudinally through the body of the stomach. As a rule, two to four straight folds can be seen along the lesser curvature, constituting the "gastric street" or "pathway of Aschoff." On the greater curvature the arrangement of the folds commonly gives a dentate appearance because folds running from the anterior to the posterior wall are seen at right angles. At the incisura angularis the longitudinal folds tend to become curved or spiral towards the greater curvature. Towards the pylorus the folds converge in a radial manner and are continuous with the folds visible on the pylorus itself.

In the first part of the duodenum the folds are arranged longitudinally, as in the stomach (Fig. 1 on Plate), although a transverse arrangement may be visible during contractions.

The mucosal folds are not fixed anatomical structures but vary in arrangement, thickness, and width, with the needs of digestion. Forssell holds that the two main factors governing the fold formation are the variations in the fluid content of the mucosa, and the action of the muscularis mucosæ under the control of its nervous regulating mechanism, the Meissner plexus.

RADIOGRAPHIC SIGNS OF ULCER

The radiographic signs of ulcer are divisible into two groups. 1. The *direct* signs consist of the ulcer niche itself, and the late results of ulceration (organic hour-glass contraction, pyloric stenosis, and duodenal deformities). 2. The *indirect* signs are indicative of disturbance of function. A diagnosis of ulcer on indirect signs should not now be made; only the direct signs are of diagnostic importance. The radiologist must show the ulcer niche or its results on the radiogram; no more—but no less—should be expected of the radiological examination. We propose to confine our attention to the direct signs of ulceration. The interpretation and significance of the indirect signs will form the subject of a further paper.

The ulcer niche, first described by Haudek in 1910, is our most valuable diagnostic sign and is pathognomonic of ulcer. Its demonstration is certain evidence of loss of substance from ulceration. If possible it should be demonstrated in two planes, "en face" and "en profile." With ulcers on the lesser curvature of the stomach this is not generally possible, such ulcers being seen in the postero-anterior view in profile.

The "en face" niche—that is, the niche as seen from the front—is as a rule only visible after a small quantity of the meal has been taken, being hidden or indistinct when the stomach is distended with the meal. Dosed compression over the ulcer area will displace the contrast medium revealing the niche and the adjacent mucous membrane in relief (Fig. 2). Such an "en face" niche is called by Berg a "relief" niche.

The recent ulcer, seen "en face," shows as a sharply defined round or oval punched-out area surrounded by a zone of inflammatory œdema. As healing takes place the "en face" niche loses its definite outline, the circular inflammatory zone disappears, the niche becomes smaller and irregular, and there may be a radial convergence of the mucosal folds towards it (Fig. 9). Finally, when complete healing takes place, a star-shaped scar replaces the niche.

The niche having been located "en face," the patient is slowly turned under screen control until the best view of the niche is obtained in profile (Figs. 2 and 3, 9, and 10). The profile niche varies greatly in appearance, being cup-shaped in the more recent ulcers (Fig. 4), and thorn or funnel-shaped in the more chronic forms (Fig. 6). On either side of the niche there is a concave indentation of the adjacent profile. This indentation corresponds to the circular zone of inflammatory œdema surrounding the "en face" niche (Figs. 9 and 10). It is the result of œdematous swelling of the surrounding mucous membrane, of infiltrative thickening of the submucosa, or of scar-tissue formation and resultant contraction. The concave indentation on either side of a profile niche is an essential accompaniment of all ulcer niches.

Berg stresses the importance of screening and of radiography in the most varied positions in order to show the niche to the best advantage and to reveal its various characteristics. Figs. 13 to 16 show how necessary this is, and how in the case illustrated it was not until the almost lateral position was reached that it was possible to demonstrate the penetrating nature of the ulcer on the anterior wall of the duodenum (Fig. 16).

Care must be exercised in estimating the depth of an ulcer because the swelling of the mucous membrane as seen in profile may make it appear much deeper than it really is. It must be remembered that the radiogram shows the stomach and duodenum as seen from the inside, and that the outer view as seen at operation may be quite different. An ulcer shown radiographically with marked indentation of the adjacent profile may not be seen or felt from the serous side, and will be seen only when the stomach or duodenum is opened. Especially is this true of ulcers situated on the posterior wall, above all if these are situated distally in the first part of the duodenum. If some time elapses between X ray examination and operation it may be found that the operative and the radiological findings do not agree. Disappearance of the mucosal swelling and rapid scarring may have taken place in the interval, especially if medical treatment has meantime been carried out. When there is a considerable interval it is advisable to make a further radiological examination a day or two before operation to determine the presence and condition of the ulcer.

The penetrating nature of an ulcer must be diagnosed with caution. It is sometimes possible to demonstrate a narrow channel between the stomach or duodenum and the accessory pocket (Fig. 16). Many penetrating ulcers, however, will show no communicating channel (Fig. 11). Similarly the presence of a gas-bubble in a niche, or the differentiation of its contents into a barium layer, a secretion layer, and a gas-bubble, while suggestive of penetration, is by no means pathognomonic. A similar appearance may be found with an ulcer confined entirely within the gastric wall. In favourable cases the aimed dosed compression exposure method will reveal the changes resulting from penetration. The mucous membrane may show a radial pointing of its folds towards the niche, and the folds may be bent sharply away from the normal longitudinal direction sometimes at right angles (Fig. 7). If in addition there is definite fixation of the stomach or duodenum at this point, as determined by manipulation under the screen, the penetrating nature of the ulcer is clear. If the pyloric portion of the stomach is projected in the left anterior oblique or left lateral position, there is normally a perspective foreshortening. The absence of foreshortening indicates fixation of the posterior wall. A similar positioning of the first part of the duodenum shows normally a perspective elongation. If, however, the posterior wall is fixed this elongation is not apparent. These findings, associated with a demonstrable niche, make it certain that there is penetration.

Occasionally it may be possible to show the perforating nature of an ulcer. Fig. 4 shows a niche with an accessory pocket, and in Fig. 5 the same niche is shown with maximum dosed compression applied. At operation it was found that the ulcer was on the point of perforation.

Unless a niche shows the typical appearances either "en face" or "en profile," or better still in both views, there is considerable doubt as to its being a true ulcer niche. A deposit of opaque meal which does not fulfil these requirements must not, without re-examination, be regarded as due to the presence of an ulcer.

In spite of every technical improvement and of the most careful and skilled examination a small proportion of ulcers will still escape detection. It is evident that no help can be expected radiologically in the diagnosis of those ulcers which are so small and superficial that they will not retain the opaque meal. Berg holds that after a recent hæmorrhage it may be possible to demonstrate the niche, because the crater may be filled as the result of coagulation or thrombosis. Forssell holds that the mucous membrane, by virtue of its power of independent movement, may temporarily close the lumen of the niche, so that thorough palpation is necessary in order to force the opaque meal into the crater.

The modern radiological demonstration of the mucous membrane can offer no help in the differentiation of a simple chronic ulcer from a carcinomatous ulcer, unless the adjacent mucosa shows the gross changes indicative of malignancy. An ulcer which is macroscopically benign, and in which the presence of carcinoma is revealed only by histological examination, will show the radiological characteristics of a simple chronic ulcer.

The diagnosis of an ulcerating carcinoma from a simple ulcer may be difficult. In the former the niche is more irregular and does not show the definite characteristics associated with niche formation, either "en face" or "en profile." As seen "en face," it tends to have the features of a profile niche. In the profile view the smooth concave indentation seen on either side of a simple niche is replaced by an irregular moth-eaten filling defect. One has the impression that something has been taken away from the outline of the stomach, whereas a simple ulcer appears to be added to the outline. In the majority of cases the demonstration of neoplastic mucosal changes in the immediate neighbourhood will leave no doubt as to the nature of the lesion.

Certain radiological appearances may be misinterpreted as the niche of a simple ulcer. Occasionally perigastric adhesions will produce a small boss in the profile view and simulate a niche. There is, however, no concave indentation of the adjacent profile, which as we have seen is an essential accompaniment of all ulcer niches, and normal mucosal folds will be demonstrable in its immediate neighbourhood. Duodenal and jejunal diverticula and the rare diverticula of the stomach may be mistaken for ulcer niches. The demonstration of radiating folds in the stalk of a diverticulum is pathognomonic. A peristaltic wave, because of its changing position, should never be mistaken for a niche. Calcareous opacities will be projected away from the gastric and duodenal contour by examining the patient in various positions.

HOUR-GLASS CONTRACTION

Radiological examination is the only certain means by which organic hour-glass contraction can be diagnosed. Aimed dosed compression exposures show a permanent abnormal direction of the mucosal folds at the site of contraction, the folds running obliquely as if associated with some degree of rotation of the proximal upon the distal sac. A chronic ulcer is always associated with it (Fig. 8).

Organic hour-glass contraction, as seen in the specimen, is never so marked nor so extensive as it appears from the radiological examination of the filled stomach, the degree and extent of the constriction being accentuated in the latter by the additional spasm which is present. Aimed dosed compression exposures, show more truly its real characteristics, by resolving the contraction into its organic and spastic components.

The differentiation of organic from spastic hour-glass contraction is a matter of therapeutic importance. With the minimal filling of the stomach, as practised in the Berg method, spastic phenomena are much less common than with distended filling, and the demonstration of the normal mucosal relief such as accompanies spasm at once differentiates it from the organic lesion. It is also possible to distinguish a simple organic from a malignant hour-glass contraction. In the latter the line of contraction is usually in the long axis of the stomach, and the stiff, hilly, irregular relief, so characteristic of neoplasm, will be seen.

PYLORIC STENOSIS

Pyloric stenosis is the commonest and clinically the most important of the late results of ulceration. It may also result from new growth, simple hypertrophic stenosis, and adhesions.

In a well-marked case the stomach is dilated and gastric secretion may be seen during the preliminary screen examination. The opaque meal falls directly through the secretion to the bottom of the stomach and collects at the lower pole in the form of a half-moon. There is delay in the evacuation of the gastric contents, varying with the degree and duration of the stenosis.

In the earlier cases the demonstration of a duodenal or pyloric niche or of characteristic neoplastic changes in the pyloric region by aimed dosed compression exposures will determine the primary cause of the stenosis. Such differentiation is of course impossible in those cases where in spite of manipulation, waiting, and prolonged observation on the screen, none of the opaque meal is seen to pass through the pylorus.

DUODENAL DEFORMITIES

Deformity of the first part of the duodenum or "duodenal cap" may be produced by spasm from an extra-duodenal lesion, by spasm and mucosal swelling, or spasm and cicatricial contraction associated with ulcer, or by contraction of the scar-tissue of healed ulceration.

A duodenal ulcer confined entirely to the mucosa may heal without producing a demonstrable radiographic deformity. In the more chronic ulcers, where the deeper layers of the duodenum are involved and where there is always some fibrosis, a demonstrable radiographic deformity will always be present, even although the ulcer has completely healed. Thus it is obvious that although duodenal ulceration, particularly the more chronic forms, is often accompanied by deformity of the cap, a deformed cap by no means implies that ulceration is present.

The differentiation of these deformities is rarely possible by the ordinary methods of radiological examination. The exact nature of the deformity can however be definitely distinguished by the aimed dosed compression exposure method. Niche formation is the only radiological sign which justifies a radiological diagnosis of ulcer. A normal duodenal mucosal relief is evidence that the lesion is extrinsic. A deformed cap with demonstrable scarring but no ulcer niche is the result of healed ulceration. Fig. 12 shows a deformed duodenal cap with scarring from healed ulceration but no niche formation.

SUMMARY AND CONCLUSION

Berg's aimed dosed compression exposure method is the most perfect method of examination at present available for the diagnosis and investigation of gastric and duodenal ulceration. By its means the fleeting image of the screen is made permanent on the radiogram.

Only the demonstration of the ulcer niche on the radiogram warrants a radiological diagnosis of the presence of ulceration. Every niche should if possible be shown in two planes, and must satisfy the known anatomical and pathological requirements of niche formation.

In a large proportion of cases it is possible to show conclusively the perforating or penetrating nature of an ulcer.

The method is invaluable in the diagnosis of duodenal ulceration and in the differentiation of the duodenal deformities. No longer is it necessary to consider the indirect radiological signs in arriving at a diagnosis of duodenal ulcer. In almost every case it is possible to demonstrate the ulcer niche.

LEGENDS TO ILLUSTRATIONS ON SPECIAL PLATE

FIG. 1.—Aimed dosed compression exposure showing: (*a*) *radial convergence of mucosal folds towards pylorus;* (*b*) the pyloric folds; and (*c*) the longitudinal arrangement of the mucosal folds in the first part of the duodenum.

FIG. 2.—Postero-anterior view of the stomach, showing "en face" niche with convergence of mucosal folds to niche.

FIG. 3.—Same case. Oblique view, showing profile niche.

FIG. 4.—Perforating niche on lesser curvature of stomach, showing small accessory pocket.

FIG. 5.—Same case, with maximum dosed compression applied, showing ulcer crater. Note absence of reactive changes (convergence of mucosal folds) showing that the ulcer is recent. The patient gave only two months' history of indigestion.

FIG. 6.—Chronic ulcer on lesser curvature near cardiac orifice, showing convergence of the mucosal folds.

FIG. 7.—*Ulcer of posterior wall of stomach penetrated* into the pancreas. The mucosal folds are pointing radially towards the niche and are bent sharply away from the normal direction. *The radiogram shows the* accompanying pyloric spasm.

FIG. 8.—Aimed dosed compression exposure of organic hour-glass contraction. (*a*) Points to chronic ulcer in the scar-tissue; (*b*) points to site of contraction.

FIG. 9.—Aimed dosed compression exposure of duodenal cap, showing "en face" niche with surrounding inflammatory zone, and radial convergence of mucosal folds towards niche.

FIG. 10.—Same case, showing profile niche with concave indentation of adjacent profile corresponding to inflammatory zone surrounding the "en face" niche.

FIG. 11.—Niche on posterior wall of first part of duodenum penetrated into pancreas.

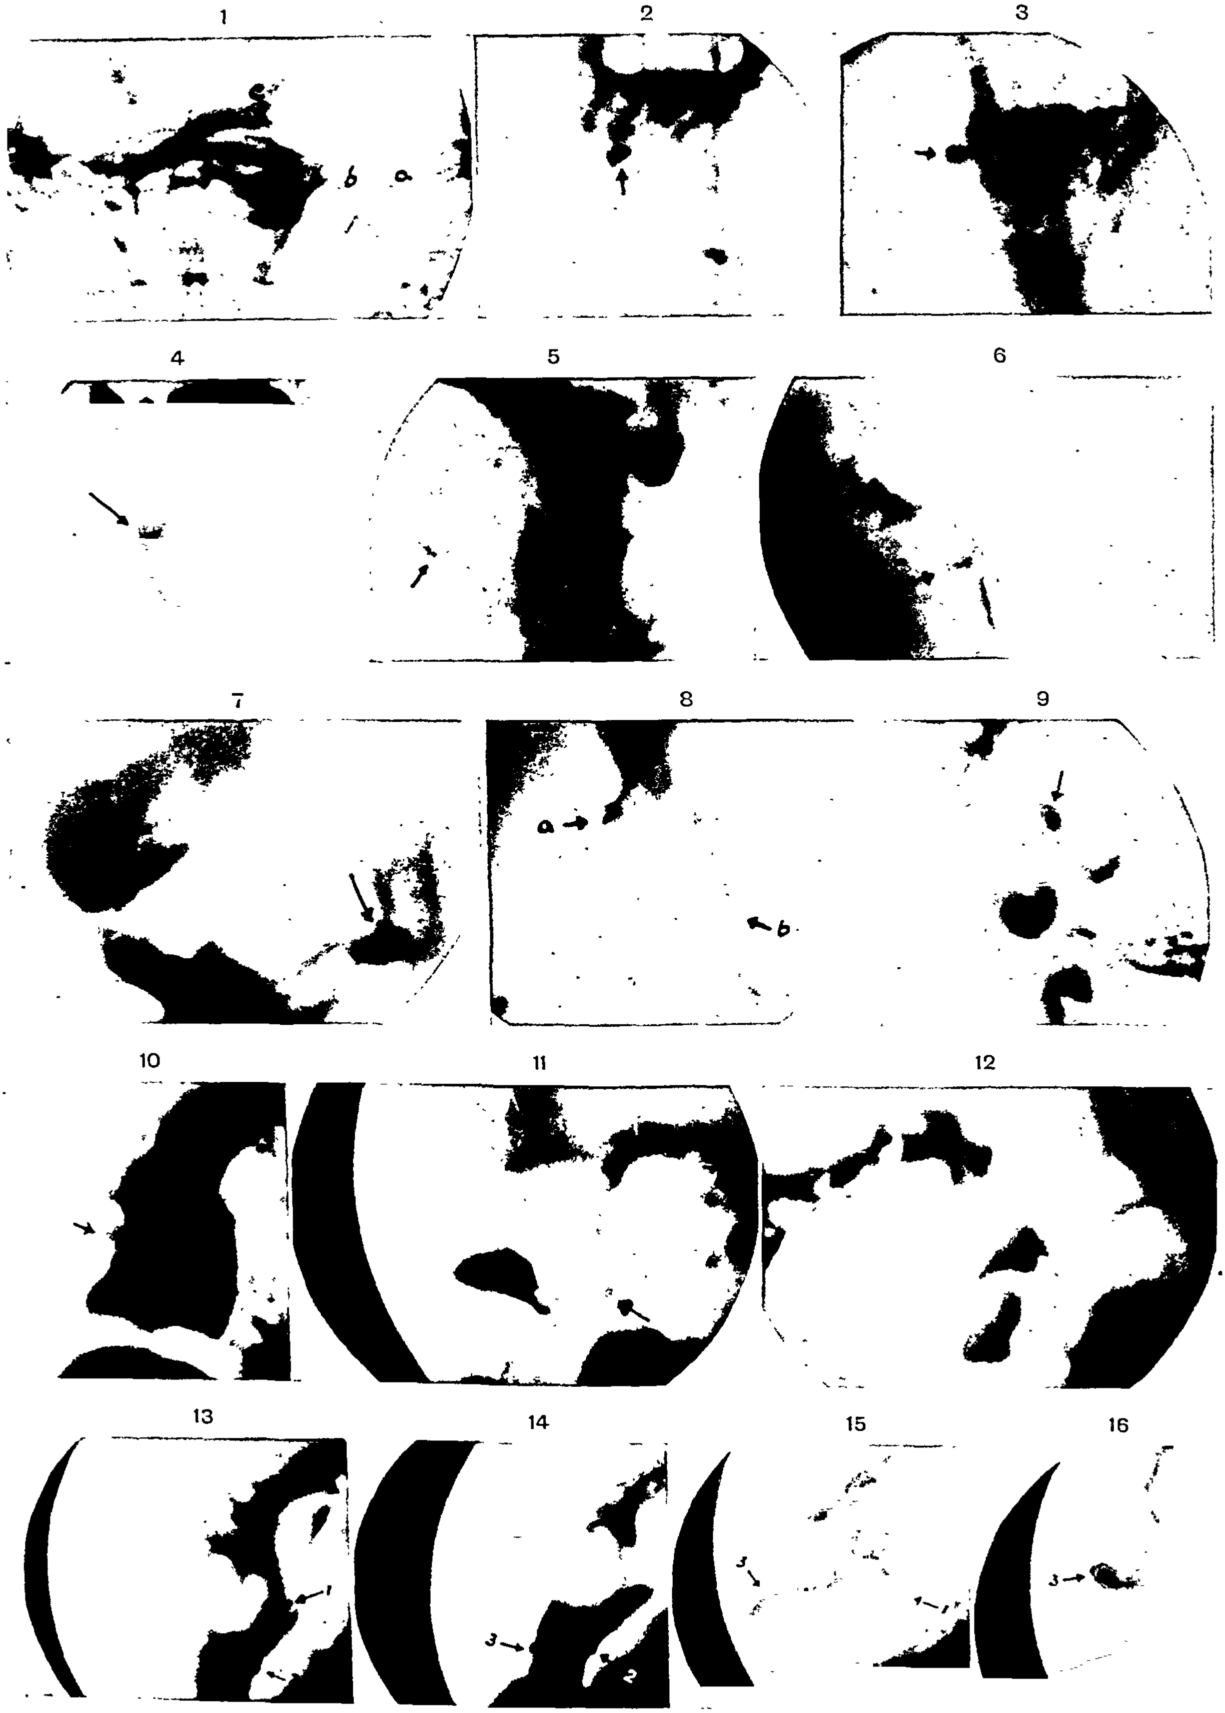
FIG. 12.—Aimed dosed compression exposure of deformed duodenal cap. No ulcer niche.

FIG. 13.—Aimed dosed compression exposure niche in *middle portion of first part of duodenum* (1) with hour-glass contraction at same level. Niche on posterior wall immediately distal to pylorus (2).

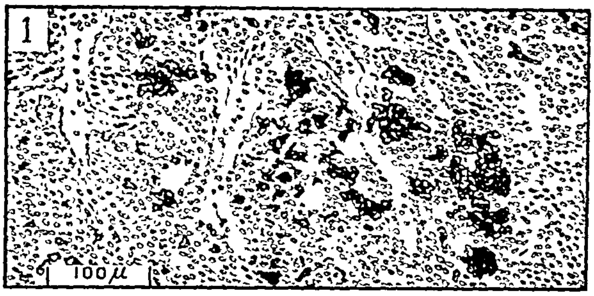
FIG. 14.—Same case, with patient slightly more rotated, showing a third niche, situated on the anterior wall immediately distal to pylorus.

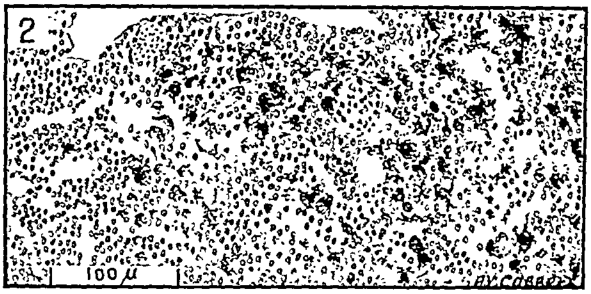
FIG. 15.—Same case at different degree of rotation, showing niches 1 and 3.

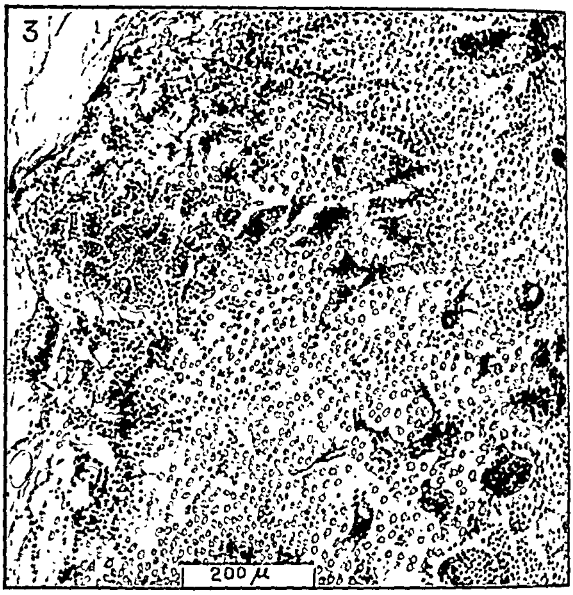
FIG. 16.—Same case (patient almost lateral), showing penetrating nature of ulcer on anterior wall. The *inflammatory zone* in the region of the ulcer is well seen, as is also the communicating channel and the accessory pocket in the liver.

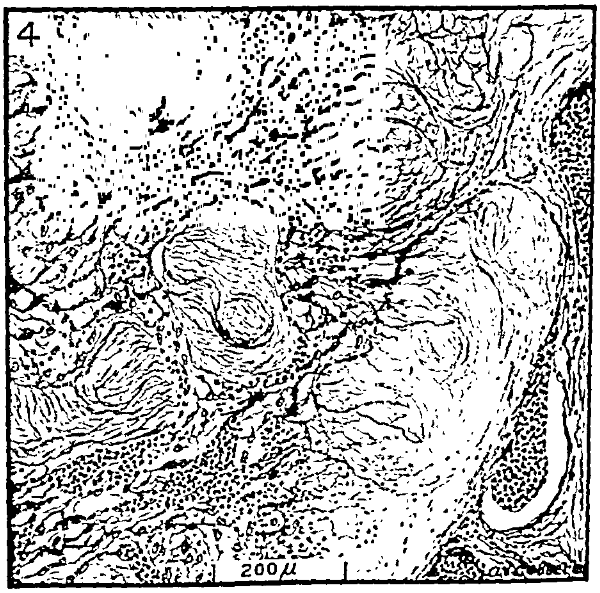


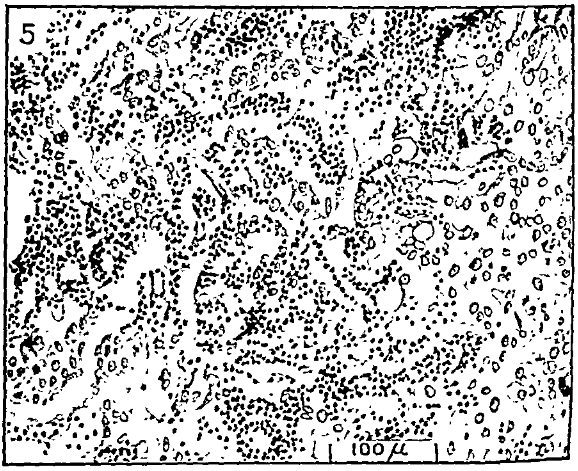
DRS. CORDINER and CALTHROP. RADIOGRAPHY OF PEPTIC ULCERATION

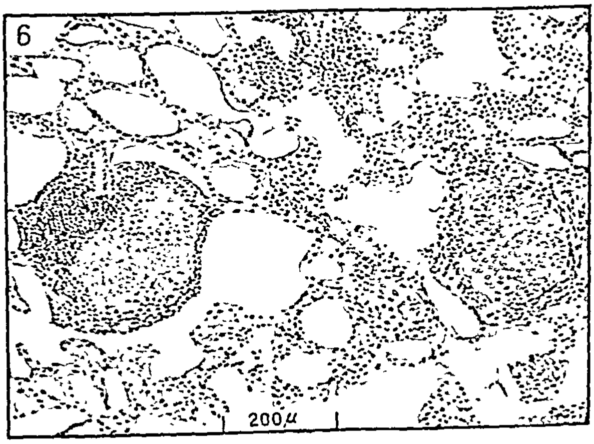


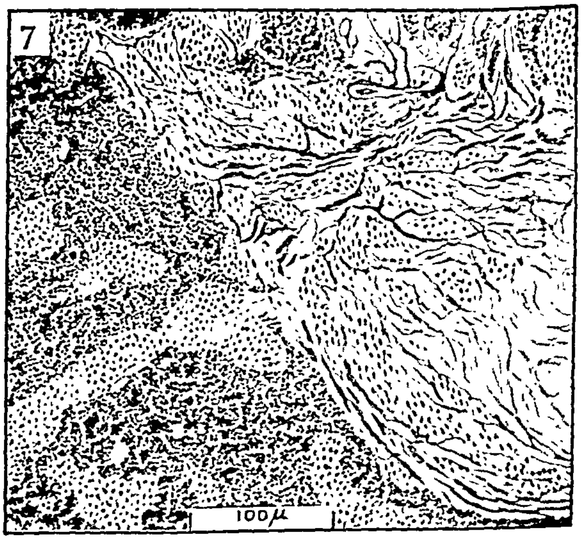












Prof. KETTLE: THE DETECTION OF DANGEROUS DUSTS

THE DETECTION OF DANGEROUS DUSTS

By E. H. Kettle, M.D., F.R.C.P. Lond.

PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF LONDON AT ST. BARTHOLOMEW'S HOSPITAL MEDICAL COLLEGE

(WITH ILLUSTRATIONS ON SPECIAL PLATE)

It is highly important that we should be able to distinguish from among the dusts that occur in so many industrial occupations those which are capable of causing pneumoconiosis.

The inhalation of particulate matter may affect the lung in two ways. It may produce fibrosis of the organ of such a degree as to be incompatible with health or even life; and it may modify unfavourably ordinary infective processes. Both these reactions must be considered in estimating the dangerous potentialities of any particular dust, for they are not necessarily manifestations of the same property. The obvious way to determine whether a substance is capable of affecting the human lung in these ways is to test its action on the lungs of animals, but this method is not altogether satisfactory for it is laborious, expensive, and, above all, time consuming. Whatever the technique employed for the introduction of the dust into the lungs, all who have worked on experimental pneumoconiosis are agreed that the end lesion, the characteristic fibrotic nodule, cannot be produced in a few days or weeks, but only in periods measurable in years rather than months, and this makes the method of little value as a practical test.

I have shown [1] for several of the substances which are common constituents of occupational dusts that they may be divided into two groups, the active and the inert, according to their behaviour when injected into the subcutaneous tissues, and that this grouping corresponds with clinical and industrial experience. The active dusts cause an acute inflammation with necrosis of tissue and subsequent fibrosis, whereas the inert dusts give rise to nothing more than a mild and transient reaction. Further, if animals in which such lesions have been produced are infected intravascularly with tubercle bacilli, clear evidence is obtained that the active dusts determine a local settlement and proliferation of the bacilli out of all proportion to what is seen in the tissues generally and in the reactions surrounding the inert dusts. This technique provides a method for testing the capacity of a dust to modify an infection; it is perhaps less legitimate to claim that it tells us whether the same substance can produce fibrosis of the lung, for there is an obvious difference between the injection of a substance into the tissues, with all the trauma this involves, and its introduction into the lungs by the natural routes.

LEGENDS TO ILLUSTRATIONS ON SPECIAL PLATE

FIG. 1.—Section of a pulmonary lymph node of a guinea-pig killed 702 days after the intratracheal injection of iron-coated silica. The dust has been deposited in the gland and has excited no reaction.

FIG. 2.—Section of a pulmonary lymph node of a guinea-pig 467 days after intratracheal injection of wellingtonite (aluminium oxide). The dust is inert and causes no reaction.

FIG. 3.—Section of a pulmonary lymph node from a guinea-pig killed 236 days after intratracheal injection of crystalline silica. The dust has excited an active histiocytic reaction.

FIG. 4.—Section of a pulmonary lymph node from a guinea-pig killed 477 days after the intratracheal injection of finely powdered flint. The reaction has proceeded to the stage of the production of fibrous nodules.

FIG. 5.—Section of a pulmonary lymph node from a guinea-pig 236 days after the intratracheal injection of kaolin. The dust is active and is causing a pronounced cellular reaction.

FIG. 6.—Section of the lung of a rat kept in captivity in a gold mine for two and a half years. There are early cellular nodules, but these have not yet proceeded to fibrosis.

FIG. 7.—Section of a pulmonary lymph node from the same rat: the cellular reaction has advanced to the stage of fibrosis.

The action of dusts on the tissues may, however, be studied in another way which is free from this objection. It has been shown that particulate matter suspended in normal saline may be injected directly into the lungs through the trachea without producing undue trauma to the pulmonary tissues.[2] Particles introduced into the lung in this way are picked up by phagocytes just as are the particles of dust inhaled in the air, and in due course some of the dust containing phagocytes reach the extra-pulmonary lymph nodes. It is well recognised that in human silicosis the earliest lesions are found in the root glands as the result of this process, and the same thing occurs in experimental pneumoconiosis. And it does not matter how the dust reaches the lungs, for although the mode of introduction may possibly have a bearing on the pulmonary lesions, it is obvious that it can have no influence on the glandular deposits which are produced by entirely natural means.

In the course of experiments carried out during the last two or three years I have found a striking difference in the reactions occurring in the extra-pulmonary lymph nodes according to whether the material introduced into the lungs was what I have termed an active dust or an inert one. If an inert dust is injected into the lungs a certain proportion of it is carried by phagocytes to the pulmonary lymph nodes. After a time the phagocyte dies and undergoes lysis, depositing its burden in the substance of the gland where it remains without causing any tissue reaction and without exciting the attention of other phagocytic cells. If the dust is active, however, an entirely different reaction takes place. No sooner is it liberated by the death of the phagocyte than it is ingested by fresh cells which appear in such numbers as to disorganise completely the structure of the node. This activity persists, and in time collagen fibrils begin to appear between the cells. The deposition of collagen is not as a rule uniform throughout the gland, but tends to be most intense in the centres of the larger collections of dust cells. It is progressive and eventually proceeds to the formation of the characteristic acellular nodule, though this may take a year or more to develop. It is, however, quite unnecessary to wait for the end-lesion to form in the lymph nodes before arriving at an opinion as to the nature of the dust; within three months a microscopic examination of them will reveal such significant changes as to make the diagnosis possible.

The distinction between the two types of dusts is demonstrated in the following groups of experiments which I have selected from my material:—

Series 1.—A sample of iron-coated silica which previous experience has shown to be an inert dust [1] was injected into the lungs of a group of guinea-pigs; 20 of the animals died or were killed at periods between 82 and 700 days after the injection. The lungs contain plenty of the dust, but it has excited no reaction whatever. The pulmonary lymph nodes were examined in 10 of the animals; they show a considerable deposition of dust, but no cellular activity and no fibrosis (Fig. 1).

Series 2.—In this experiment the dust used was wellingtonite, another inert substance; 18 animals survived for periods between 32 and 467 days. These lungs contain dust, but show no reaction, and the pulmonary lymph nodes which were examined in 8 of the 18 cases show a copious deposition of dust but no fibrosis or cellular activity (Fig. 2).

Series 3.—In this experiment the dust used was a chemically prepared sample of crystalline silica, the average-sized particle being between 1 and 3 μ. The pulmonary glands of 11 guinea-pigs which survived for periods from 94 to 726 days after the injection were examined. They all show an active macrophage reaction (Fig. 3), and two of them from the animals surviving for the longest period show nodular fibrosis. The lungs in these animals show plaque formation and cellular nodules, but no nodular fibrosis.

Series 4.—The material used in this experiment was a sample of finely ground flint; 75 per cent. of the particles measured 0·8 μ or less; 26 animals survived for from 72 to 477 days after the injection; the lungs were examined in all of them and the pulmonary glands in 20. The lungs all show an active histiocytic reaction, and in some of them there is a varying amount of fibrosis of the infective type. In two of them killed 477 days after the injection there is definite, though early, nodular silicotic fibrosis. All the glands show an active cellular reaction, and in 4 of them examined 417, 469, and 477 days after the injection, there is pronounced fibrosis of the silicotic type (Fig. 4).

These experiments bring out quite clearly the difference in the reaction induced in lymphadenoid tissue to active and inert dusts. They are far from exhaustive, for though they have been supplemented by observations on other dusts I have not tested out systematically a large series of substances; but the results are so clear-cut, and correspond so well with those obtained by other methods of investigation, that it seems reasonable to conclude that lymphadenoid tissue reacts fairly specifically to the two main types of particulate mineral matter, and should prove a valuable test tissue for the detection of dangerous dusts.

An interesting application of the test is seen in a series of animals treated with kaolin. This is a silicate of aluminium and there is no very definite evidence that it constitutes an industrial hazard, though I have met with one case of human pneumoconiosis apparently due to it; experimentally, however, it appears to be an active substance.[1 3] The pulmonary glands of seven guinea-pigs which survived for from 163 to 505 days after the injection of this dust into the lungs all show an active reaction, though this has not proceeded to actual fibrosis (Fig. 5), and a very similar reaction is present in the lungs.

It will be noted that in the experiments recorded the lungs reacted actively to the dusts which produced changes in the lymph nodes, and a microscopic examination of them gives quite satisfactory evidence that wellingtonite and the sample of iron-coated silica worked with are inert and harmless dusts, whereas kaolin and flint are active and harmful. If the pulmonary lesions were always as distinct there would be no need to look elsewhere for our information; but, as Haynes has shown,[4] dusts which have never been regarded as dangerous may cause cellular reactions in the lungs of animals indistinguishable from the early lesions produced by silica and other substances undeniably capable of causing pneumoconiosis; and I have myself seen pleural drift, plaque formation and a moderate degree of fibrosis, that is, the accepted signs of an incipient pneumoconiosis, with such an inert substance as carbon (Indian-ink).

The danger of placing reliance on anything but unequivocal end-lesions in the lung is shown very well in experiments with iron-coated silica. The injection of this substance into the lung excites an immediate cellular response; the particles are engulfed by single and giant phagocytes and the appearances are those of an active pulmonary reaction. But in a few weeks the signs of activity pass off; much of the dust is now lying free in the alveoli, and there is nothing to suggest a subsequent fibrosis. A further advantage which the lymphadenoid tissue has over the lung when one is testing out dusts is the relative rapidity with which recognisable lesions develop in it. This is well seen in material kindly sent me by Dr. Andrew Watt and Dr. J. Pratt Johnson, of Johannesburg, from rats which had been kept underground in one of the Rand mines. The lungs (Fig. 6) show early cellular lesions but no trace of fibrosis, but the pulmonary lymph nodes show not only the characteristic cellular reaction but actual fibrosis (Fig. 7).

I have no exact information as to the earliest times at which one might expect to find positive results, for the main object of my experiments was the study of the later pulmonary lesions, and animals dying during the first few weeks have usually been discarded. Glandular lesions, however, are well developed in 94 days in the first animal of Series 3, and in Series 4 recognisable reactions are present after 72 days. It would seem therefore that three months is ample time in which to determine by this test whether a dust is active or inert.

When questions of considerable medico-legal importance are concerned, pathological evidence should be as conclusive as possible, and it may be argued that nothing short of the demonstration of its capacity to produce absolutely typical pulmonary lesions is sufficient to incriminate a dust. But this is a counsel of perfection, and it seems highly probable that a correct opinion as to the nature of a dust can be reached by a combination of indirect observations of which the one here described is by no means the least important.

FAILURES OF GASTRIC SURGERY *

By J. A. RYLE, M.D., F.R.C.P. Lond.
PHYSICIAN TO GUY'S HOSPITAL, LONDON

IN their decision to devote an evening to the discussion of therapeutic failures, the officers of the society are to be congratulated. I would even express a wish that this discussion may be regarded as a forerunner of others and that it may become customary to review at one session annually the limitations of our powers as healers in other branches of medicine or surgery. We know only too well that, as individuals, we commonly learn more from our disappointments than from our successes. By a pooling of unsuccessful experience we have surely a better prospect of discovering the causes of error and of improving standards of practice than by keeping it to ourselves.

Although some methods become established and perfected more rapidly than others it is clear that all true advances in therapeutics must pass through an experimental phase, in the course of which indications are sifted and technicalities developed. During this phase results are found to vary considerably in relationship with individual judgment and ability.

---

* Address delivered in opening a discussion at the Medical Society of London on April 23rd.

Gastric surgery is no exception. It has evolved swiftly in the last quarter of a century, but the results have had to be waited for; immediate benefits have often given place to later disappointment; and, with a very human impatience for achievement, technique has often been cultivated more studiously than judgment. Of this there is now a wide appreciation. Our self-criticism, however, should take the form not of condemnation but analysis, and if I may be permitted, in some degree, to direct the trend of this debate I would straightaway suggest that we do not allow our remarks to degenerate into a competitive advocacy of medical measures as opposed to surgical, or of one surgical method as opposed to another, but rather that we should seek to discover patiently and dispassionately the main causes of failure, the main consequences of failure, and the best means of promoting an increase in our tale of successes in the future. There has been, from time to time, a tendency for the surgeon to decry the physician and vice versa in respect of the treatment of peptic ulceration, both parties disregarding the obvious inclination of medical failures to drift to the surgeon and of surgical failures to drift to the physician, while each remained uncertain as to the proportion of successes obtained and the types of case most successfully handled by the other. This antagonistic habit of mind is surely unbecoming and unphilosophical. In a problem so difficult there should have been collaboration, not competition, all along the line.

In considering what contribution I might make as opener of this discussion I have encountered difficulties from the outset. Not least among these was the decision as to what constitutes a failure. Let me first endeavour to answer this question, for it is one in respect of which we must find common agreement. Having thus cleared the ground I propose to consider briefly: (1) the causes of failure, other than those connected with technique, which lies outside my province; (2) the types of failure, their symptomatology and treatment; and (3) the avoidance of failure in so far as this is connected with clinical judgment and selection of cases.

WHAT CONSTITUTES A FAILURE?

Perhaps I can best reply to this question by citing certain recognised eventualities.

(1) An anastomotic ulcer developing within a year or two of an operation for dyspepsia due to an active, non-obstructive duodenal ulcer is a failure in that a worse condition than that for which the operation was undertaken has ensued, and, frequently too, in that the operation was not an essential undertaking.

(2) An anastomotic ulcer developing after an operation for stenosis (unless technique be to blame) is in a sense less of a failure, for here there was no reasonable alternative to the treatment adopted.

(3) An anastomotic ulcer following eight or ten years after an operation for duodenal ulcer, with good health intervening, can hardly be recorded in the same category as the early recurrence and is almost as entitled to be called a success as a failure.

(4) A gastro-jejunostomy complicated by a mechanical difficulty, such as vicious cycle vomiting or a "dumping" stoma, but accomplishing healing of the ulcer, is only a partial failure, but also only a partial success.

(5) Death or recurrence following gastrectomy undertaken for a very large adherent ulcer of the lesser curvature, causing serious pain and proved to be beyond the hope of medical relief, is hardly, in my opinion, to be regarded as a failure. In such cases to do nothing is unthinkable, and yet the scales are heavily weighted against surgical success.

(6) Death or recurrence or a gastrectomy anæmia following gastrectomy undertaken for a small lesser curvature ulcer or an ulcer of medium size lacking an adequate medical treatment I should regard as consequences of a grave failure of judgment.

(7) A relieving gastro-jejunostomy for an obstructive pyloric carcinoma, which gives comfort for a period of months, does not cure but is certainly not a failure.

(8) A fatal gastrectomy for an extensive non-obstructive carcinoma of the stomach, in view of the inevitable issue if no operation is performed, is not to be regarded as a serious failure, but where general rather than local symptoms predominate I am persuaded that the decision to operate in such cases often represents a failure of judgment.

Briefly I would suggest that an operation which leaves the patient immediately no better or worse than before, or which results in death in conditions which might have been cured or considerably palliated by medical means, must be regarded as a failure. In the case of recurrent ulceration after operation the degree of success or failure is partly to be assessed by the duration of good health. In cases in which operation for an ulcer has resulted in the healing or eradication of the ulcer but also in digestive discomforts or ill-health of another kind—i.e., vicious cycle vomiting, intestinal dyspepsia, diarrhœa, gastrectomy anæmia—success is clearly only of a partial kind.

THE CAUSES OF FAILURE

These may, as has been indicated, be subdivided into those due to technical error or surgical inexperience, and those due to faulty selection or judgment. Others again, but probably a minority, are due to incidental misfortunes or lack of coöperation on the part of the patient.

Faulty judgment may be held to include decisions to operate in cases in which there is no sufficient justification for surgery at all, or in which medical treatment has been given no trial or an insufficient trial, or in which the patient's general state of health or the circumstances of his life at the time make surgery an unwise procedure. Inadequate attention to the anatomical, physiological, or psychological peculiarities of the individual, any or all of which may render a case unsuitable for surgery, also leads to errors in judgment. A decision to operate for an unsuitable symptom such as hæmorrhage or too soon after a hæmorrhage is another type of judicial error. It is in respect of assessments such as these that the surgeon, employing too narrow a pathology and too concentrated upon the local aspects of treatment, has sometimes shown himself defective.

TYPES OF FAILURE AND THEIR SYMPTOMATOLOGY

I am familiar with five complications of gastro-jejunostomy deserving the qualification of partial or grave failure. These are, in order of ascending gravity and frequency: (*a*) the dumping stoma,[†] (*b*) vicious cycle vomiting, (*c*) peri-anastomotic hæmorrhagic gastritis, (*d*) persistence of the original ulcer, and (*e*) anastomotic ulcer. Anastomotic ulcers may cause a painful and often intractable dyspepsia, or again be complicated by hæmorrhage, perforation, stenosis, and (the gravest complication of all) gastro-jejuno-colic fistula.

The two important complications of gastrectomy are recurrence of ulceration and gastrectomy anæmia, which may be either of the simple or pernicious type.

The symptoms of the "dumping stoma" are flatulent discomforts and distension around the navel and below the gastric area of reference following soon after a meal. In a small proportion of cases there is diarrhœa with passage of light-coloured stools in which undigested food-particles may be recognised. In such cases a short rest after meals in the recumbent posture should be enjoined and fluids taken apart from meals.

[†] This term is used to describe a condition in which food leaves the stomach precipitately through a too patent stoma, with rapid overloading of the small bowel.

In vicious cycle vomiting there are recurring attacks of discomfort or pain with copious bilious vomiting. Such attacks may appear soon after the operation of gastro-jejunostomy and disappear later. In a small proportion of cases they persist and reoperation may become necessary. They are, I believe, a consequence of technical flaw.

Recurrent hæmorrhages after gastro-jejunostomy *without* pain or dyspepsia may be due to local ulceration or to a diffuse peri-anastomotic gastritis, a condition with which Dr. A. F. Hurst has familiarised me. Treatment should generally be medical, particular pains being taken by liberal administration of iron to combat anæmia at all times. Only in the graver cases and after a full trial of medical measures should a partial gastrectomy be considered.

In anastomotic ulceration the pain is commonly severe but very similar in type and time-relationships to the pain of the original ulcer. It is less responsive to medical treatment. The maximum tenderness is usually found one and a half inches above and to the left of the navel. Prolonged trials of medical treatment should be made before advocating further surgery, but they are much less frequently successful than in the case of a primary gastric or duodenal lesion.

In gastro-colic or gastro-jejuno-colic fistula there are added to the clinical syndrome of anastomotic ulcer diarrhœa (continuous or intermittent), eructations of colonic flatus, loss of weight and, in some cases, severe anæmia. The treatment must be surgical.

THE AVOIDANCE OF FAILURE

In so far as this depends upon other factors than technique I would urge first the importance of close attention to the age, physical and mental type, general fitness, family history, occupation, habits and economic status of the patient, and secondly, to the duration of the ulcer-history. Neither the very old nor the very young make such good subjects for gastric surgery as those in the middle period of life. In the case of young men in the twenties the ulcer is necessarily of more recent arrival, obstructive and other mechanical complications (such as anchorage of the ulcer-base) are more rare, and coöperation in the matter of post-operative caution is less easily ensured. In patients over 60 the operative risks are sufficiently greater to make the decision to perform either a short-circuit or a partial gastrectomy a more doubtful one.

A strong family history of duodenal ulcer emphasises the likelihood of constitutional predisposition, in the face of which the best surgery may fail. The lean, nervous, and anxious-minded patient—a fairly common type among the victims of duodenal ulcer—often suffers more in the post-operative phase and is more liable to retain dyspeptic discomforts. The rushed and restless business man, the doctor, and the man too much addicted to alcohol and tobacco are all, to my thinking, unfavourable types for gastro-jejunostomy, even though they may be difficult to keep well by medical means. For men of the working classes, whose cases would in better circumstances be considered more suitable for medical treatment, operations may sometimes have to be advised (even recognising the risks of failure) as they cannot afford long periods of rest or the dietaries which would be necessary as alternative treatment. Anæmia and oral sepsis or concurrent ill-health may raise the risks of surgery sufficiently to make palliative measures preferable.

The duration of ulcer symptoms is an important deciding factor. There are very few patients with histories of recurring ulcer dyspepsia of under five years, and lacking obstructive symptoms for whom I would willingly suggest an operation. Recent hæmorrhage and recurrent hæmorrhages I have come to regard as actual contra-indications to gastro-jejunostomy unless other arguments, such as mechanical complications or the large size of the ulcer weight the scales in its favour. In a Hunterian lecture in 1932[1] I referred to 12 cases of duodenal ulcer with hæmorrhage of which 9 were apparently subjected to gastro-jejunostomy on the strength of hæmorrhage. Of these 12 cases 8 bled again subsequently.

A rapid emptying time in duodenal ulcer as judged by radiology or the fractional test-meal and a high "up and down" peak of gastric acidity are to be used as arguments against a short-circuit. A slow emptying time and a steadily climbing curve of acidity are relatively favourable to a short-circuit.

Positive indications for surgery are perforation; pyloric or mid-gastric stenosis; a chronic posterior duodenal ulcer with the particular syndrome pointing to anchorage to or erosion of the pancreas; a chronic duodenal ulcer complicated by duodenal ileus; and chronic duodenal or gastric ulcers estimated to be of large size and long standing which have resisted prolonged and careful medical treatment. Even with attention to these precautions I have knowledge of three cases selected and referred by myself to surgeons of first-class experience in which secondary ulceration followed a short-circuit. Ulceration may also recur after gastrectomy and it will be some years before we can assess the final benefits of this increasingly frequent operation.

The final decision should never be based on any rule-of-thumb method, but must be made in each instance by a careful review of all the available evidence, both of a general and a local kind. So difficult may this decision be that it should commonly require the coöperation of physician and surgeon. In neurological and thoracic surgery such coöperation is generally regarded as sound and reasonable. Every operation should be followed by an adequate period of dietetic treatment and controlled by tests for occult blood in the stools. Interrupted courses of iron and a bi-weekly ration of liver or liver extract should be advised after gastrectomy.

CONCLUSION

In borrowing from my own fairly considerable experience of surgical failures, for I have mentioned no complication of gastric surgery which I have not personally seen, I may seem to exaggerate their frequency. This I have no wish to do. Actually for every ten cases of duodenal ulcer seen in private practice I see one case of anastomotic ulcer, but in all probability the frequency of this, the most important type of failure, taking all surgeons of all grades of experience, would still be less than 10 per cent.

We should not, however, be actuated in our caution solely by the numerical frequency of failures, but also by their gravity, and we must reluctantly confess that when gastric surgery fails to relieve it commonly leaves the patient in worse case than before. This cannot be said of medical treatment, however high we estimate its failures to be, excepting in so far as these failures may leave a liability to the graver accidents. It has been argued that surgery protects from dangerous complications such as perforation and hæmorrhage, but this needs qualification. I have referred elsewhere[1] to 23 cases of gastro-jejunostomy in which there had been no bleeding prior to operation and in 10 of which bleeding occurred later, and to 7 cases of anastomotic ulcer with a history of previous duodenal perforation, in 3 of which perforation had occurred again.

---

[1] THE LANCET, 1932, i., 327.

The triumphs of surgery are more complete and lasting than those of medicine, but, by the very nature of the risks taken, the failures of surgery are also more complete and more lasting. Excepting therefore in urgent or obvious situations the responsibility of deciding upon operation must remain a serious one and should require every contribution we can muster from balanced experience and prognostic insight. Improving technique has greatly diminished the immediate mischances of gastric surgery. Improving clinical judgment and physiological studies should ultimately help to eliminate or greatly diminish those mischances which follow at a later date.

FAILURES OF GASTRIC SURGERY*

BY A. JAMES WALTON, M.S., B.Sc. Lond.,
F.R.C.S. Eng.
SURGEON TO THE LONDON HOSPITAL

THE days when a surgeon only required to know how to operate are long since past, and now one of his most important functions is to decide when to operate. Every operation that is unnecessarily performed is a surgical failure yet, in spite of the close coöperation between physician, laboratory worker, and surgeon, such failures are only too frequent. In gastric surgery they fall naturally into two groups.

Errors of diagnosis.—If an operation has been performed in the belief that a gastric or duodenal ulcer or a gastric carcinoma is present and the expected lesion is not found, surgery has failed at its very inception. The underlying condition is not improved and is often made worse. The patient has been subjected to a definite risk of life, to a period of some days of grave discomfort and pain, and to a further period of some weeks or more of limited activity. His life and work have been gravely disturbed and to a varying extent he may have been financially embarrassed. Yet there is no surgeon who can honestly state that he has been free from this fault. It is true that to-day we no longer hear the suggestion made that the symptoms are anomalous and it would be better to look inside and see what is wrong, and but rarely are we told that medicine has failed and that surgery had therefore better be tried. Very few surgeons will now consent to operate unless there is very strong evidence of the presence of an organic lesion which can only be cured by operative measures, but our knowledge is still so incomplete that errors in diagnosis are even now made and the abdomen unjustifiably opened.

The error most frequently occurs when the presence of carcinoma is suspected, and here perhaps the mistake is more pardonable. for the disease, if left too long—and often indeed, if left until the diagnosis is certain—becomes inoperable, so that operation upon suspicion alone is often justified. Moreover, the settlement of all doubt and the relief to the patient from his dread suspicion may do much to set him on the road to recovery. It is difficult to estimate with any accuracy what number of cases are so operated upon, for most surgeons, myself included, index their cases under proved lesions and do not keep any list of their suspected duodenal or gastric lesions, although they are often entered up on the individual notes.

I find, however, that in my statistics which were last analysed in August, 1933, I have operated upon 2172 proved gastric lesions and upon 171 cases which have been indexed as gastritis, or some other non-surgical gastric lesion. That is to say, in a series of 2343 operations there was a percentage of 7·2 errors of diagnosis (Table I.).

TABLE I.—*Errors of Diagnosis*

		Errors.	Per cent.
Total operations ..	2343	171	7·2

Operative Mortality

	Total.	Deaths.	Per cent.
P.G.E. for duodenal ulcer	703	14	2*
P.G.E. for all uncomplicated lesions ..	846	25	2·9
Wedge resection for lower curve ulcers..	272	12	4·4

* Includes series of 283 with no death.
P.G.E. = posterior gastro-enterostomy.

Although most of these were operated upon in the belief that carcinoma was present, yet the percentage is much too high.

Operations for medical lesions.—The second serious error is to perform an operation for a lesion which could be cured medically. In all patients the fear of operation is a very real one, and those of us who have been honoured by having many doctors among our patients will realise that this is not limited to the ignorant. The figures of such cases are, however, not assessable, for they are very largely a matter of personal opinion. Many physicians believe that they are much higher than do the surgeons, and probably Dr. A. F. Hurst, for instance, would place them a good deal higher than I should ; but the two branches are to-day approaching agreement on this point, and it is now generally accepted that all early ulcers should be treated medically, that all chronic ulcers if uncomplicated should be given a trial of medical treatment before surgical intervention is sought, that the more unsuitable the patient for operation the longer the trial, and that as a general rule the shorter the history of gastric symptoms the greater the probability of carcinoma. and therefore the sooner should surgical intervention be undertaken.

Because of our wider knowledge of the after-results and the closer coöperation in the work of the physician and surgeon, we much less frequently see to-day operations performed for visceroptosis, for chronic colitis, and other lesions which can be more readily relieved by medical measures. In the same way gross errors of diagnosis and treatment, such as the performance of gastro-enterostomy for tabes dorsalis, chronic uræmia, and the vomiting of pregnancy very rarely occur.

OPERATIVE MORTALITY

Even to-day there is no operation which is free from risk and in every case this risk must be balanced against the danger of the lesion. Such a balance can only be arrived at after wide experience and a full knowledge of the patient's general health. The teaching that a given lesion must be treated by a certain operation is useful for the undergraduate but is futile in practice. The risk will depend upon the age of the patient, the presence of local or general complications, and the experience of the surgeon. If the first two are advanced and the third is retarded the risk of operation may easily exceed that of the lesion, and therefore either no operation should be performed or some palliative measure should be executed. This variation in the patient's risk is well exemplified by the curious experience of many surgeons that their mortality-rate rises with their experience. The explanation lies in the fact that an increasing proportion of patients who are aged, who are excessively fat, or who have some other counter indication to operation are sent to them for treatment. In spite of this the basis of analysis must be a knowledge of the mortality in different series operated upon by the individual surgeon. The larger the series the more accurate the figures, for both good and bad risks are more likely to be included. An enormous number of such figures have been published. Surgeons especially skilled in this branch of work have reported remarkably low mortality-rates, whereas the opponents of operation have collected statistics of operations performed, perhaps by many surgeons, which show a much higher mortality. With a discussion of the value of these figures I do not propose to weary you, for this has been done on frequent previous occasions. I shall simply mention a few figures obtained from the study of my own statistics which were analysed up to August, 1933. These figures, as already mentioned, comprise a total of 2172 gastric operations.

---

* Contribution to a discussion at the Medical Society of London on April 23rd.

The operation which is most frequently criticised to-day is that of gastro-enterostomy, for many claim that it is associated with a relatively high mortality and is followed by a grave risk of after complications. It will be seen, however, from my figures (Table I.) that in 703 cases of duodenal ulcer the mortality was only 2 per cent. and these cases included a consecutive series of 283 operations without a death. Even when performed for lesions other than duodenal ulcer its mortality only rises to 2·9 per cent., so that the dangers of operation are not excessive and in my experience do not in any way equal those of hæmorrhage and perforation in patients who have had no operation. Ulcers of the lesser curve of the stomach carry with them a rather higher operative mortality, as is well recognised, and in 272 of these patients treated by wedge resection and gastro-enterostomy, which to my mind is the operation of choice, there were 12 deaths, a mortality of 4·4 per cent.

It must always be remembered, however, that these figures, although relatively low, must in a sense be regarded as an added risk to the disease. It is but little consolation to a patient's relatives to know that a serious risk which might eventuate in two or three years' time has been completely removed if the patient dies shortly after operation.

OPERATIVE RESULTS

Before discussing the individual causes of post-operative failure it is necessary to know the percentage of cures. This can only be estimated by investigating a considerable number of cases. As with the operative mortality, diversity of opinion has led to much criticism of published statistics. I will therefore make no attempt to discuss the published results, but will only show you some of my own figures and will lay stress upon the fact that a patient who is described as a cure is one who can eat anything and can continue his daily work. Many of the patients who attend my follow-up department are dock labourers and stevedores, who have for their mid-day meal meat and bread with perhaps an onion and a piece of cheese, and if unable to partake of this diet cannot continue their work. They have no opportunity of living upon the diet which is so often insisted upon for those who have obtained a medical cure. In determining whether the patient has reached this standard it is, of course, essential that his progress has been watched for a considerable time, and for this reason the preparation of statistics of after progress is always a laborious work. I shall give you the figures I published for the collective investigation of the British Medical Association, for this series of cases was watched for a minimum period of five years, the longest period being nine years. Of 172 duodenal and pyloric ulcers treated by gastro-enterostomy, 84·9 per cent. of all cases, or 88·8 per cent. of those followed, were cured. In 67 cases of ulcer of the lesser curve treated by a wedge resection, the figures were somewhat higher, being 88 and 92·18 respectively. The partial gastrectomies were associated with a higher mortality, so that the figures were 70·2 and 74·2 respectively (Table II.).

TABLE II.—*Five-year Cures after Operation*

	Total.		Per cent. of *all cases.*		Per cent. of *followed cases.*
P.G.E. for pyloric and duodenal ..	172	....	84·9	....	88·4
Wedge resection for lower curve ulcers	67	....	88	....	92·1
Partial gastrectomy	37	....	70·2	....	74·2

P.G.E. = posterior gastro-enterostomy.

It has been necessary to lay some stress upon the successes before considering the failures, for there are very definite and well-recognised failures which occur in the hands of every surgeon and which at present it is difficult to prevent. To-day great stress is being laid upon them and there is a danger of their frequency and importance being exaggerated and the real use of these valuable operations being overlooked. Therefore in any discussion such as this, which is mainly limited to a consideration of the failures, it is well to keep constantly in mind that they form but a small proportion of the total.

Probably every surgeon has from time to time met with the rare examples of failure due directly to errors of technique or to rare accidents. The former, among which may be mentioned such gross errors as uniting the stomach to the lower ileum or even to the transverse or pelvic colon, making an opening which is much too small, allowing the afferent loop to become constricted by the mesocolon, placing the anastomosis on the wrong side of an hour-glass constriction or uniting the posterior wall to the anterior, are with increasing knowledge becoming extremely rare. They are failures not of gastric surgery, but of grossly incompetent gastric surgery. Post-operative hæmorrhage is also probably due to errors of technique which, however, are less evident and thus less easy to avoid. Among the rare accidents may be mentioned herniæ through the opening of the mesocolon or behind the afferent loop and retrograde intussusception through the gastro-enterostomy opening. The former may be prevented by careful technique, but the latter, although very rare, seems to occur even when the operation has been most carefully performed.

Considerable discredit is falling to-day upon gastric operations owing to certain complications and failures which have been much discussed. These are four in number, and it is to them that our attention must be mainly directed. They are: (1) gastro-jejunal ulcer, (2) recurring ulcer, (3) subsequent development of carcinoma, and (4) post-operative anæmia.

GASTRO-JEJUNAL ULCER

The frequency of this serious and dangerous complication has been much discussed. Many physicians seeing chiefly the failures after gastro-enterostomy believe that it is a common event. Hurst states that it is a frequent and dangerous sequel to gastro-enterostomy after duodenal ulcer, and that the number of marginal ulcers slowly and steadily increases the longer the cases of gastro-enterostomy are watched. He quotes the remarkable series published by Lewisohn in 1925 of 68 cases of gastro-enterostomy, 34 per cent. of whom later developed this complication. Similar though not quite such extreme views are held by many surgeons, especially those on the Continent, and for this reason they have given up gastro-enterostomy in favour of partial gastrectomy. On the other hand, surgeons who have carefully watched their cases have shown that the incidence is somewhere in the neighbourhood of 3 per cent. It is manifestly impossible here to enter fully into these much-discussed figures. This I have done in a communication, an abstract of which I am giving at the meeting of the Association of Surgeons and which I hope will later be published in full. I have for this purpose analysed my cases up to August, 1933, and have arrived at certain very definite conclusions which may be summarised as follows and which are based upon the figures shown in Table III.

TABLE III

Total cases 2172.
Marginal ulcers (with local resection) 18. Recurrences 6.

		Gastro-jejunal ulcers and per cent.	
Total cases	2154	31*	(1·4)
G.E. and gastrectomy	1859	31	(1·6)
Posterior G.E.	1313	29	(2·2)
Gastrectomy	469	2	(0·43)
Duodenal ulcer	893	29	(3·24)
Duodenal ulcer watched 10 years	457	18	(3·9)
Gastric ulcer	683	1	(0·14)
Carcinoma	221	0	(0)

* One recurrent.
G.E. = gastro-enterostomy.

1. Gastro-jejunal ulceration is only common after gastro-enterostomy for duodenal ulcer.
2. It occurs after 3–4 per cent. of all such operations.
3. It is much more common in males.
4. It is directly due to hyperacidity.
5. The hyperacidity is congenital and possibly a familial fault.

The mortality of gastro-enterostomy should not exceed a maximum of 2 per cent., whereas after partial gastrectomy it is very seldom less than 6 per cent. Thus the mortality of the latter operation is greater than that of gastro-enterostomy together with the incidence of marginal ulceration, and it is not justifiable to replace gastro-enterostomy by partial gastrectomy, which should be used only for the few cases which have developed a marginal ulcer.

The greater frequency in males has long been recognised. In the 30 cases following my own operation of gastro-enterostomy there was only one female. In 49 further cases in my series where the gastro-enterostomy was performed elsewhere there were 6 examples. The reason why these ulcers are almost entirely limited to males in whom a gastro-enterostomy has been performed for a duodenal ulcer has now been proved to be due to the fact that in such patients there is a much higher acidity. At one time it was thought that errors of technique such as the use of a button, of unabsorbable sutures, or of clamps was the exciting cause. Such may increase the incidence, but they are only a contributory factor. If there is a high acidity the ulcer may develop in the absence of such factors. Although not entirely absent after partial gastrectomy, they are less frequent as this operation brings about a greater reduction of acid. The careful experimental and clinical work which has proved that a high acidity is the cause is too long to discuss here, but on the clinical side we owe most to the work and writings of Hurst. My own figures, as shown in Table IV., entirely support this view. Hurst also shows that not only is hyperacidity a congenital fault, but there is often a family history not only of duodenal ulcer but of gastro-jejunal ulcer following gastro-enterostomy. It would appear that this extreme degree of the hyperæsthenic gastric diathesis is present as a congenital fault in some 3–4 per cent. of all cases of duodenal ulcer.

TABLE IV.—*Average Test-meals*

		Cases.	Average free HCl.	Average total acid.
Lesser curve	Females	57	0·108	51
	Males	135	0·123	61
Duodenal	Females	44	0·136	57·6
	Males	213	0·165	63·5
Duodenal, later gastro-jejunal		13	0·19	71

Because of this underlying fault any form of local operation or any method of undoing the gastro-enterostomy is useless in the treatment of these ulcers. The only operation that holds out any hope of success is a partial gastrectomy, sufficiently extensive to reduce the acidity. It is a serious and irksome operation and associated with a high mortality, but in dangerously ill patients a temporary palliative operation may be performed and the gastrectomy carried out later when the patient's condition has improved. By a careful selection of such cases and experience in the operative technique the mortality can be greatly reduced. In my last series of 20 cases there was only one death.

RECURRENT ULCERATION

At one time there was much discussion as to the value of gastro-enterostomy in the treatment of ulcers of the body of the stomach, but it is now generally agreed that this method is not sufficient. It is true that some very large ulcers found in patients who are dangerously ill from hæmorrhage, or vomiting, or continued pain, are entirely cured by a gastro-enterostomy which was performed as a palliative measure, but a considerable number, especially of the penetrating ulcers, still persist. In my own series there were 117 cases of lesser curve ulcer treated by gastro-enterostomy alone, and in five of these the ulcer persisted (Table V.). Of greater interest are the cases where new ulcers arise after a gastro-enterostomy. I have for long upheld the view that duodenal ulcers do not persist or recur after a properly performed gastro-enterostomy. I have never yet met with such a case where the stoma was functioning and was accurately placed. I believe that most of the cases described as such recurrences are really gastro-jejunal ulcers. The cases to which I refer now are those in which the ulcer develops on the lesser curve after the performance of a gastro-enterostomy for duodenal ulcer. Such cases are rare (Table V.), there being only 4 in a total of 865

TABLE V

		Total.	Recurrent ulcers.	Carcinoma.	Severe anæmia.
G.E. for	duodenal ulcers	865	4	6	0
	gastric ulcers	117	5	1	0
G.E. and resection for gastric ulcers		325	6	5	1
Partial gastrectomy		469	0	0	5
Suture for perforation		—	32	—	—

G.E. = gastro-enterostomy.

gastro-enterostomies for duodenal ulcer, but the mere fact that they can arise is the strongest argument against the routine use of gastro-enterostomy alone for lesser curve ulcers.

Another interesting group of cases is that in which an ulcer persists after simple suture for a perforation. I have long maintained that the majority of perforations occur with chronic ulcers, for in nearly all my cases a prolonged history had been obtained, and of a series of 42 perforations examined post mortem 41 were definitely chronic ulcers and one was doubtful. Nevertheless many surgeons claim that most of the perforations occur with acute ulcers and that a simple suture is alone necessary to bring about a cure. As with so many other points in gastric surgery this matter has given rise to much discussion, but that many ulcers do persist in spite of simple suture is beyond all question. In my own series there have been 32 cases where a simple suture was performed elsewhere, but persistence of the symptoms necessitated further operation. I have no means of determining the percentage of such persistence, for I do not practise suture alone as a routine method. Many similar cases have, however, been reported by other surgeons. Although my experience therefore favours the view that most of these ulcers are chronic, it must not be thought that I would advocate the routine performance of gastro-enterostomy on all occasions in cases of perforation. If the patient's condition is sufficiently good I should undoubtedly carry it out at that time, but if he is gravely ill and there has been flooding of the peritoneal cavity, a simple suture alone should be performed: but the important point is that under such conditions the patient should never be told that he is cured, but should be carefully watched and a further operation advocated if the ulcer persist. In nearly all such cases that I have seen where this course has been followed a later operation has been required.

SUBSEQUENT ONSET OF CARCINOMA

The relationship of carcinoma to chronic gastric ulcer has always been a vexed question. Its onset has not only been reported after gastric operations other than partial gastrectomy but the frequency of this complication has been regarded as another reason for the substitution of gastro-enterostomy or local excision by a partial gastrectomy. Paterson [1] discussed this question in 1926 and stated that in 493 of his cases 2·5 per cent. were said to have died subsequently of carcinoma. He found, however, that many of these cases were doubtful, and that he was only able to find one case in which the carcinoma was undoubtedly gastric, and in that case it had not occurred at the site of the ulcer.

In my own series there were 1307 cases treated by gastro-enterostomy with or without resection of the ulcer, and in this series there were 12 cases (0·91 per cent.) which subsequently developed carcinoma. These, however, fall into three distinct groups. There were, firstly, those in which a gastro-enterostomy was performed for an ulcer so large and so adherent that a partial gastrectomy was considered unwise, and in which, although at the time of the operation the lesion was considered to be benign, yet the evidence of carcinoma developed so shortly afterwards that there could be no doubt that the ulcer was carcinomatous at the time of the operation. In such cases the lesion was manifestly inoperable, and even if a partial gastrectomy had been performed recurrence would certainly have followed. These cases are, therefore, no indication for the replacement of gastro-enterostomy by a partial gastrectomy.

In the second group a gastro-enterostomy is performed for an ulcer in the duodenal or pyloric region, which ulcer is apparently healed, and after a period of varying time a carcinoma develops in some part of the stomach remote from the primary lesion. Such a carcinoma is no more prone to occur in these cases than in normal persons, in fact, it is probably less so, for these patients have a hyperchlorhydria, while carcinoma, as the work of Hurst tends to show, is more prone to occur in those who have hypochlorhydria. Hence to suggest that a case of duodenal ulcer should have a partial gastrectomy performed in order to prevent the later onset of carcinoma, is even less sensible than to suggest that all normal persons should have such an operation lest at a later date they develop carcinoma, or that all young women should have a hysterectomy lest they develop carcinoma of the cervix. In my own series there were 3 such cases, the carcinoma occurring 3, 15, and 17 years respectively after the gastro-enterostomy (Table VI.). The remaining group comprises those cases in which the carcinoma occurs in the same area of the stomach in which the ulcer was situated, and although it may arise many years afterwards, it is fair to assume that it originated in the scar of the old ulcer. The carcinoma may be situated either within the pyloric region or on the lesser curve and sufficient time has elapsed to make it certain that it was not present at the time of the first operation, and thus its onset would have been prevented if a partial gastrectomy had been performed. In my own series there were five cases which were placed in this group, and although in three of them a second operation was not performed, either the site of the tumour as found on clinical examination or the X ray appearances suggested that the scar of the old ulcer was involved in the carcinoma. But even if they all belong to this group there were only five cases in a series of 1307 gastro-enterostomies, that is a percentage of 0·37, so that the risk of this complication cannot be considered as great. These five cases occurred 4, 4, 5, 6, and 6 years respectively after the first operation. It will be noticed (Table V.) that there were no cases of carcinoma following a partial gastrectomy.

TABLE VI

Total cases	1307
Total carcinoma	12 (0·91 %)
Present at first operation	4
Remote from site of ulcer	3
Occurring at site of ulcer	5 (0·37 %)

POST-OPERATIVE ANÆMIA

Of late years much has been added to our knowledge of anæmia, and it is now realised that Addisonian or pernicious anæmia is due to the absence of a substance formed by the action of a constituent of the gastric juice upon the protein of beef muscle. It would therefore be expected that this form of anæmia would occur after complete gastrectomy and, in fact, Moynihan pointed out as far back as 1911 that this complication did occur. It has since been realised that it may also be found after a partial gastrectomy and even after a gastro-enterostomy, although the explanation of this occurrence is not so simple. Many cases of anæmia following gastric operations are found, however, not to be of the macrocytic or pernicious type, but to be simple or microcytic and due to the absence of available iron. The frequency of these two types has been much disputed. Rowlands and Simpson [2] collected 15 cases of the Addisonian type from the literature and added

2 more of their own. Of the 17, 5 occurred after total gastrectomy, 8 after partial gastrectomy, and 4 after gastro-enterostomy. Gordon-Taylor[3] found 8 cases of mild anæmia and 15 of severe after 52 partial gastrectomies, but these did not resemble the Addisonian type. Morley[4] also found that 12 out of 21 Polya operations developed anæmia, but none occurred after the Schoemaker operation. Vaughan[5] collected 122 cases of anæmia, which had been fully investigated, following gastric operations, but achlorhydria was not present in all of them. Hurst[6] collected five cases of undoubted macrocytic anæmia, but states that although this variety is rare the simple microcytic anæmia is quite common. There is no doubt that mild forms of anæmia are not uncommon after a partial gastrectomy, but the frequency of the more severe types is uncertain. It is possible now that this more extensive operation is being so widely performed, especially on the Continent, as a routine operation for all gastric lesions that a large number of severe anæmias will soon have to be treated. It has also been very noticeable in my follow-up department that when a partial gastrectomy has been performed for a lesion which was associated with severe hæmorrhage previous to the operation that the anæmia may take a very long time to improve, but the majority respond in time to large doses of iron. In my own experience the condition is very rare after gastro-enterostomy (Table V.), there being no example after 982 operations. There was one case following 325 local resections and five cases in a group of 469 partial gastrectomies. These cases were all of the microcytic type.

Clinical and Laboratory Notes

THE TREATMENT OF SCHISTOSOMIASIS WITH ACRIFLAVINE

By A. C. Fisher, M.B. Brist., F.R.C.S. Eng.

RESEARCH WORKER UNDER ROYAL SOCIETY GRANT AT BAPTIST MISSIONARY SOCIETY HOSPITAL, YAKUSU, HAUT CONGO BELGE

The possible utility of acriflavine in the treatment of schistosomiasis, suggested itself to me during some in-vitro experiments, in which it was found that this drug was rapidly lethal to the bilharzial cercaria in high dilutions in the presence of human blood-serum. The value of acriflavine in general medicine and surgery is so well known that it need not be touched on here. The fact that it is readily absorbed when taken by the mouth would make it a valuable weapon against schistosomiasis were its specific properties proved.

The cases treated in this series were all of a type of schistosomiasis found in the Stanleyville district of the Belgian Congo, where intestinal bilharziasis is caused by a parasite of the *hæmatobium-bovis* group whose peculiarities are now being studied. The series comprises 52 cases; of these 30 were under twelve years of age and the remainder ranged up to forty. The sexes were about equally represented. The first two patients treated received intravenous injections of acriflavine, but in all subsequent cases the oral route was used exclusively. The course consisted of five doses given on consecutive days, and the drug was given in a 2 per cent. aqueous solution, on an empty stomach, at least an hour before the next meal. In cases where dysentery was absent it was found that a daily purge made the treatment more efficacious. The dosage was regulated to age and weight according to the following scale:—

Children weighing 20 kg. or less were given a total dose equivalent to 0·02 g. per kg.

Children weighing 30 kg. were given a total dose equivalent to 0·015 g. per kg.

Adults weighing 60 kg. or more received a total dose equivalent to 0·01 g. per kg., with a maximum dose of 0·7 g.

Of the 52 cases in the series, 13 continued to show ova in the fæces unchanged. Of these 11 were small children who had received a total dose equivalent to less than 0·012 g. per kg. of body-weight. The remaining 39 cases became symptom-free in less than three days, and ceased to show any but degenerate eggs in the stools within the week. The first two cases treated were under observation for two months without the recurrence of symptoms or the reappearance of schistosome ova in the fæces. No toxic manifestations were observed in any of the patients treated, nor have any unpleasant sequelæ been encountered.

The results recorded in this preliminary note seem sufficiently good to justify acriflavine being given a more extensive trial in the treatment of the three types of human schistosomiasis.

VULVOVAGINITIS IN CHILDREN

By C. Paget Lapage, M.D. Manch., F.R.C.P. Lond.

PHYSICIAN TO THE ROYAL MANCHESTER CHILDREN'S HOSPITAL AND CHILDREN'S DEPARTMENT OF ST. MARY'S HOSPITAL; LECTURER ON DISEASES OF CHILDREN IN THE UNIVERSITY OF MANCHESTER

Chronic vulvovaginal discharge is not uncommon in young girls under the age of 14, and may lead to much discomfort, mental and physical, to the child and the mother. Often, but not always, a swab shows the primary infecting organism. In some cases the discharge appears to be simply one of other chronic catarrhal states of the mucous membranes in a debilitated child and might be put in the same category as chronic catarrh of the nasopharyngeal mucous membrane or the respiratory or gastro-intestinal tracts. The nature of the infection is therefore not always clear, and a swab may simply show a mixed infection.

Again, infection with the most intractable and pathogenic organism of all, the gonococcus, is not always easily demonstrated because the swab in chronic cases may show many pus cells but no clear evidence of the organisms. The gonococcus offers a prolonged resistance to treatment and the diseases it produces may be devastating in their effects. Consequently it is much the most to be feared. The *Bacillus coli* is frequently found in the swabs but is not necessarily causative.

The bacteriological results, however, are not the only important criteria for treatment. The volume of the discharge, its persistence, and the mental and physical state of the patient are enough to determine the need for treatment. Ordinary methods such as swabbing, gentle irrigation with antiseptics, and even searching douching with ballooning of the vagina are not always effective.

G. C. Schauffler[1] describes a new method of treatment with a 1 per cent. silver nitrate ointment made up with anhydrous wool fat. Small metal tubes (collapsible) are filled with the ointment and a piece of rubber tubing is attached to the nozzle of the tube. This rubber tubing nozzle is inserted into the hymenal opening of the vagina and the ointment is injected by pressure on the metal tube from the bottom. The injection is painless and none of the cases treated at hospital have complained of any after-effects or local irritation. The results are very encouraging, as will be seen from the following records :—

CASE 1, aged 6½, had had vaginal discharge for ten months, being treated for general debility. A vaginal swab was negative for pus, albumin, and gonococcus. From July 4th–22nd, 1932, 1 per cent. silver nitrate ointment was injected into the vagina daily for the first week, then every second day for a week, and twice during the third week. The vaginal discharge had decreased considerably after two treatments and had disappeared by the end of the first week. There has been no return of the condition. Swab was negative on May 24th, 1933. There was a recurrence in August, 1933. Six daily treatments and three treatments on alternate days were given, and there was no recurrence up to November, 1933.

CASE 2.—A child, aged 12 years 9 months, had had for several months a vaginal discharge associated with vague abdominal pains. A vaginal swab showed pus and coliform bacilli. She was given a similar course of injections to that of Case 1. The discharge had disappeared by the end of the second week. There was slight return of the discharge three months after the treatment but the condition cleared up without any further injections. Another slight recurrence appeared in March, 1933. A swab was negative for pus, albumin, and gonococcus in May, 1933. Up to November, 1933, there had been no return of symptoms.

Nine cases have been treated. Many of them have now been under observation for months since the course was given and most of them have shown no recurrence.

The swab examinations were made by Dr. Annie Somerford and the treatments carried out by Dr. Jenny Craig, to whom I am indebted for her interest and her careful notes on the cases.

CONGENITAL PYLORIC STENOSIS IN FIRST COUSINS

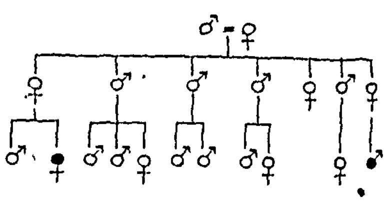
BY E. A. COCKAYNE, D.M. Oxon., F.R.C.P. Lond.

PHYSICIAN TO THE MIDDLESEX HOSPITAL; PHYSICIAN TO OUT-PATIENTS, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET

CONGENITAL pyloric stenosis has been recorded several times in more than one member of the same sibship and once in a *mother and child*. W. P. Sheldon and I have also reported a pair of uniovular twins, both of whom had this defect of development. There can be little doubt that the condition has a genetic basis, though the way in which it is inherited is still uncertain, and an environmental factor may be necessary for its production in addition to the genetic one. In the course of the last two years I have come across two instances of its occurrence in first cousins, and the diagnosis was verified in all four babies when a Rammstedt's operation was performed.

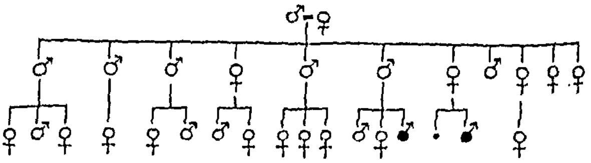
Pedigree 1.—The boy, a first child, was seen at the Hospital for Sick Children, Great Ormond-street, on Sept. 3rd, 1931, and was operated on successfully soon afterwards. His first cousin, a girl, had been operated on previously for the same condition at St. Mary's Hospital, Plaistow, and she also recovered. The mothers of the two babies were sisters: four of their brothers were married and had normal children, and one sister was married, but childless. There was no consanguinity of parents in either case and no previous history of the defect having occurred before in the family was obtained.

Pedigree 1



Pedigree 2.—The boy was seen at the Hospital for Sick Children on March 9th, 1933, at the age of 7 weeks. He was operated on and made a good recovery. He is a third child with an older brother aged 7 years and a sister aged 5. His first cousin, aged 15 months, is an only child, but his mother had a miscarriage early in her first pregnancy. He was operated on at the Royal Free Hospital in January, 1932, and the surgical registrar kindly informed me the existence of pyloric stenosis was confirmed at the operation, from which he made a perfect recovery. The parents of these first cousins were brother and sister, and there were four other brothers and two sisters, all of whose children were normal, and one brother and two sisters unmarried. There was no consanguinity of parents and no history of any other cases of pyloric stenosis in the family.

Pedigree 2



None of the parents of these four babies suffers from dyspepsia, nor are they aware that they had vomiting or other digestive disturbance in babyhood.

It is probable that the occurrence of the condition in collaterals is fairly common and a history of it might be obtained more often, if a careful inquiry was made in every case. I think the publication of these two fully authenticated pedigrees is of value, because it provides further evidence that congenital pyloric stenosis is an inherited defect.

DONATIONS AND BEQUESTS.—The late Miss Elizabeth Lindsay, of Dundee, whose personal estate is valued at over £17,000, among other bequests left, on the expiration of the life rent of her brother and sister, £1050 to Dundee Royal Infirmary for the endowment of a bed in memory of her father, and £100 to the Royal Victoria Hospital, Dundee. The residue of the property is to be divided equally between Dundee Royal Infirmary, for the children's ward; the Sick Children's Hospital, Glasgow; the Sick Children's Hospital, Edinburgh; the Mukden Medical Hospital, and three other institutions.—By will the late Mrs. Amelia Ann Gardiner, of Harrogate, left £500 to the Yorkshire Home for Chronic and Incurable Diseases; £500 to the Harrogate Infirmary; and £500 to the Cancer Hospital, among other bequests. A share of the residue of the property will also go to the National Institution for the Blind, the Yorkshire Home for Chronic and Incurable Diseases, and the Harrogate Infirmary.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF OBSTETRICS

AT a meeting of this section on April 20th, with Prof. W. BLAIR BELL, the president, in the chair, a paper was read by Dr. MAX CHEVAL, of Brussels, on

Ovarian and Uterine Grafts

Dr. Cheval said that he proposed to consider only ovarian autografts—i.e., cases in which portions of ovary were removed from the patient and grafted into her. In most of the diseased ovaries removed, sufficient healthy fragments could be found to be worth transplanting; these portions preserved the ovarian function for a period which Dr. Cheval had not yet been able to determine. The ovarian autograft should be used, he said, in almost all double oöphorectomies. It was particularly important to graft fragments of the superficial part of the ovary, and to avoid handling the parts in such a way as to destroy the germinal epithelium and the subjacent layer of primordial follicles. Intramuscular grafts, and even subcutaneous ovarian grafts, were successful in all cases operated upon aseptically. If the grafts were composed of sufficiently healthy tissues, the ovarian hormone proportion in the organism was maintained at a normal level. The uterine graft was very easily effected in subcutaneous cellular tissue. At first, experimentally, there was found to be an intense reabsorption of uterine products, and that was explained by the luteal change of the ovaries. At a later stage the small endometrioma adapted itself to its new position and, more than a year afterwards, displayed undoubted signs of vitality. Grafts of ovaries in hysterectomised bitches exhibited phenomena of follicular atresia, sometimes cystic. After six months fewer follicles remained, but some were clearly about to mature. Ovarian grafts performed in conjunction with uterine grafts showed a much less degree of atresia. After six months both kinds of grafts showed plain signs of activity. In hysterectomised women under 40 uterine grafting should be performed whenever possible in order to maintain stronger vitality in the ovarian grafts. Between the ages of 40 and 50 ovarian grafting alone should be performed, while after 50 grafts were useless.

The experiments which Dr. Cheval described were of three kinds: (1) uterus left in situ and intramuscular ovarian grafts made; (2) ovarian autografts after bilateral ovariectomy and total hysterectomy; (3) uterine and ovarian autografts after bilateral ovariectomy and total hysterectomy. When ovaries were grafted into muscle or into cellular tissue only the superficial part of the ovary took root, and not until three or four months after grafting did the primordial follicles commence to show activity. No attempt should be made to assess results until that period had elapsed. Dr. Cheval showed a large series of colour slides of the grafts of the three kinds at various stages. When a piece of uterus was planted under the skin the uterine glands showed a strong reaction; they secreted a great deal of mucus, dilated, and often became cystic. One of the cases described in detail was as follows. On Dec. 3rd, 1932, a hysterectomy for uterine fibromatosis had to be performed on a woman aged 26½. An ovarian graft was implanted into the rectus abdominis, in accordance with the Blair Bell technique, and a fragment of the uterus was grafted into the subcutaneous cellular tissue. When seen in February last, the patient complained of pains felt in the region of the uterine graft, at more or less regular intervals, the pains being accompanied by a livid coloration in the region of the operation wound. The graft, which had been implanted very superficially, could be easily felt as a small cylinder, 4 cm. long and 1 cm. in diameter. It was very probable, he thought, that the slight pains noted by the patient occurred at the time of the menstrual period; this was confirmed by the slight subcutaneous ecchymosis. The woman now had no menopausal disturbance, and the grafts were functioning 14 months after the operation. In a large series of cases, when ovarian grafting was done and the uterus was left in position, menstruation was re-established in over 80 per cent. of the grafted cases. Dr. Cheval was convinced that the vitality of autogenous grafts of the ovary was enhanced by the hormones produced by the uterine mucosa.

DISCUSSION

Dr. HERBERT SPENCER said that it had been his custom to leave an ovary or part of an ovary behind whenever possible when performing hysterectomy; in his experience most of those patients remained in perfect health. Out of 325 cases of total hysterectomy for myoma, he had had three in which malignant disease supervened in the part of ovary left behind, in one of the cases a sarcoma, after many years. If ovarian grafts became the vogue he feared there would be a proportion of late malignant sequelæ. With a uterine graft he thought it would be difficult to attain the degree of sterility which followed ovarian grafting. Infection was another factor which must be guarded against in grafting. He hoped that the researches being conducted into the constitution of the hormones would ultimately result in extracts potent when taken by the mouth or in the form of suppositories.

Mr. A. S. PARKES, Sc.D., said that Dr. Cheval had not only recalled the practicability of making grafts of the ovary, but had produced evidence that the presence of uterine tissue could have a material effect on the health of such ovarian grafts. As a result of animal experiments, such as those by Dr. Cheval, much was now known concerning the behaviour of isolated pieces of ovarian tissue, and though the human subject would not necessarily react in the same manner; the experiments showed anyhow what might be attempted. The presence of ovarian tissue was essential for the maintenance of the uterus, and this correlation was substantiated by the experiments. In only one case had removal of the uterus been found to have a definite effect on the ovarian cycle. Loeb found that the life of the corpus luteum after hysterectomy was prolonged to three times its normal length in the guinea-pig, but this had not been confirmed in regard to other animals. The speaker suggested that the recently discovered stimulating action of the anterior lobe of the pituitary body might be used in maintaining the health of the ovarian graft. The possibility of using an ovarian graft to alleviate menopausal symptoms, natural or artificial, was closely bound up with the problem of the cause of the menopause. The ovarian cycle was regulated from the anterior pituitary body. At the menopause did the ovary gradually cease to function because the required stimulus from the anterior pituitary body had ceased to become available, or did the ovary so change that it could not further respond to stimulus from the anterior lobe? If an ovary was removed from an immature animal and grafted into an ovariectomised animal of adult age, that immature grafted ovary would undergo development and become mature long before it would have done so in the environment of the immature animal. And if an ovary was taken from an adult animal and grafted into an immature animal, this grafted ovary regressed, and did not show further development until the host became adult. The rapid maturation of the ovary grafted into the adult animal was caused by the immediately available anterior lobe hormone. Clearly there was a very delicate mechanism of control, but it was certain that the stimulating action could be used for increasing the activity and maintaining the health of ovarian grafts. In operations near the menopause great benefit would probably result from the administration of anterior lobe of pituitary extract at the time of the operation.

Dame LOUISE MCILROY had done some grafting experiments years ago on rabbits, and later on monkeys; she now felt, however, that there was no place for autografting, though there was a place for grafting the ovary of another person. If even a fragment of ovarian tissue remained it was infinitely better to leave it in its normal position than to remove and graft it. She had had no experience of grafts of the uterus.

The PRESIDENT said that he had himself carried out ovarian grafting 218 times since 1912, but the operation had been sadly neglected by British gynæcologists. He had always maintained the importance of preserving the natural connexions of the normal ovary when possible. Only those structures should be removed which were diseased beyond hope of recovery or were a source of danger, function being conserved whenever possible. Ovaries were of metabolic and psychological value to the patient. Both clinical and experimental investigations had shown that ovarian grafting was practicable. In neoplasms it was often possible to preserve a portion of the ovary with its blood-supply, as the tendency of innocent tumours was to grow away from the hilum. Only autogenous grafts should be used; and his custom was to attach a ligature to the graft and keep it in the peritoneal cavity until actually used. He preferred to remove most of the dense capsule of the human ovary. It was not necessary to preserve the superficial follicles, as they were liable to become cystic, and experiments showed that interstitial cells alone sufficed to keep the uterus functional. The material to be used he sliced in a criss-cross fashion on a rubber pad. He usually implanted the graft in a blood-free nidus among the fibres of the right rectus abdominis. The President said that 106 of his 218 patients were between 17 and 30 years of age, and 90 between 31 and 40. In 201 the indication for the operation was salpingitis, in 16 the presence of innocent neoplasms of ovaries. There were five deaths after the operation; in 79 cases the after-histories were not obtained. Menstruation was possible in 113 cases, and it occurred in 80, or 70 per cent. of the cases analysed. In 14 menstruation was absent but the menopause was averted. In the 21 hysterectomy cases menstruation was impossible. Usually menopausal symptoms occurred for a few months after the operation, indicating complete removal of ovarian tissue from its normal site. Sometimes the onset of menstruation was not long delayed, the secretion formed in the grafted tissue being absorbed immediately; but in those cases a fragment of ovary might have been left behind. In some cases menstruation continued normally for years; one patient, now aged 40, had continued to menstruate for 15½ years. Dr. Cheval's use also of grafts of the uterine mucosa was of great interest. Alban Doran and others had stated many years ago that the gonads atrophied after pan-hysterectomy, and in 1906 the President had expressed the view that the uterus had an internal secretion, which he named "uterin"; he now felt less certain of this. As, however, menstruation itself was of importance to the patient, he considered that when performing supravaginal hysterectomy for fibromyoma in young women, some endometrium should be left. Of his 218 cases, the operation was the wedge-shaped fundal removal in 122, the low supravaginal in 27, and total hysterectomy in 18. In an analysis made of his cases up to 1925 of wedge-shaped removal, he found that 68 per cent. of the patients who had an ovarian graft had subsequently menstruated, whereas 89 per cent. of the women in whom an ovary was preserved in situ menstruated. He thought ovarian grafting in the human subject was capable of further improvement, and he suggested that prolan should also be administered to stimulate the functions of the graft. Even at the present time the percentage of successes showed the method to be scientific, practicable, and beneficial.

MEDICAL SOCIETY OF LONDON

A MEETING of this society was held on April 23rd, with Sir JOHN THOMSON-WALKER, the president, in the chair. Dr. JOHN RYLE and Mr. A. J. WALTON read the papers published elsewhere in this issue on

Failures of Gastric Surgery

Dr. EUSTACE CALLENDER *said that his experience* of gastric surgery was confined to gastro-enterostomy for the relief and cure of duodenal ulcer, and in the cases in which he had advised this operation it had been *completely and permanently successful*. It was eminently successful in suitable cases, and many failures of gastric surgery could be avoided by careful selection. Much responsibility in this respect rested with the general practitioner, who knew the patient and his family.

Sir WILLIAM WILLCOX, speaking of jejunal ulcer following operation, said he would not put the proportion as high as Dr. Ryle's 10 per cent. Recurrence at the site of anastomosis was very unsatisfactory, and much more difficult to deal with than the original ulcer. He agreed with Mr. Walton that posterior gastro-enterostomy was the safest operation for the "three-way tap cases." Mr. Walton's figures had confirmed the speaker's view that carcinoma very rarely developed in an ulcer.

Dr. G. E. VILVANDRÉ referred to cases in which the appendix was removed for symptoms actually due to duodenal ulcer. Lack of adequate investigation might thus make it necessary to undertake a second operation. Four times he had come across a well-marked gastric ulcer on the small curvature, some distance above the stoma. It was difficult to see how a gastric ulcer could follow a gastro-jejunostomy, but possibly a minute ulcer had been present at the time when the first operation was performed. *Or it might* be that the conditions causing a duodenal ulcer were still present to cause a gastric lesion.

Mr. DONALD BARLOW said he had always regarded partial gastrectomy *as far too radical a remedy* for ulcer of the stomach. The condition seemed to demand physiological rest for the organ, both as regards movement and the passage of hydrochloric acid and food over the ulcerated surface. Acidity could easily be neutralised. He suggested that one means of securing this rest would be, after emptying and cleaning the stomach, to paralyse its nerve-supply temporarily—e.g., by crushing the vagal nerves and allowing them to regenerate.

Dr. ERNEST YOUNG said the use of the duodenal tube would secure a good deal of rest for the stomach. Although bathed in a highly acid fluid, the ulcer managed to heal, and it seemed unnecessary to make the gastric contents alkaline. He agreed with Dr. Ryle that operation was contra-indicated in patients—usually young people—with duodenal ulcer and very rapid emptying of the stomach. Such cases almost always in his experience turned out to be surgical failures. He asked what procedure Mr. Walton adopted for a patient with both gastric and duodenal ulcer. He had found that such patients responded very well to duodenal feeding.

Mr. W. H. OGILVIE thought that the surgical failures in the cases under discussion constituted a more serious problem than some of the speeches might suggest. Few surgeons saw their own failures; in twelve years he had seen only two recurrent ulcers of his own, but had operated upon 30 anastomotic ulcers in patients whose primary operation was done elsewhere. Unnecessary and early operations for duodenal ulcer were responsible, he thought, for the majority of the surgical failures, and surgeons who had duodenal ulcer were generally in favour of medical treatment for themselves. Another cause of failure was the performance of operations which were unsound in theory and unsuccessful in practice; among these he included local resection of ulcers, the Billroth II. operation, and all anastomoses between afferent and efferent loops of the stomach—none of which did anything to counteract the causal acidity. He was also against posterior gastro-jejunostomy, while admitting that technically it could be regarded as an operative gem. It used to be thought that if a patient had no distress for three years after a gastro-jujunostomy he was permanently cured, but he had seen recurrence of symptoms as long as 30 years afterwards. The only way in which excessive acidity could be permanently reduced was the safe procedure of radical gastrectomy—i.e., removing at least four-fifths of the stomach. But before operating one should be certain that medical treatment had been given every possible chance.

Dr. MAURICE SHAW said that ultimately success or failure must depend on the skill with which cases were selected for operation, and which cases should have medical treatment. When surgery had been decided upon, the operation was not the *beginning* and the end of treatment. By following out a modified diet after operation he had had a large number of radiological cures, and several cases of relapse after operation had been rehealed by medical treatment. There were very few ulcers for which he would not try medical treatment before advising surgery. He asked whether Mr. Walton removed the appendix as a routine measure in gastric and duodenal cases.

Dr. J. R. WYLIE exhibited a table in which were given the results of operation in 492 gastric and duodenal cases. He had found very little evidence that carcinoma started in an ulcer. X rays gave a 75 per cent. accuracy in diagnosis.

Dr. RYLE, in reply, said that anastomotic ulcer was the commonest and most serious sequel of operation, and there were no means of ascertaining its frequency. Probably Mr. Walton's figures were true for expert surgeons, but these operations were being done all over the country, by competent and incompetent alike. He was particularly troubled by the case of high acidity and rapid emptying of the stomach.

Mr. WALTON said he did not make a practice of removing the appendix in these cases. Since 1919 his follow-up department at the hospital had been so active that he had not lost sight of a case. In reply to Dr. Young he said that when a patient had both a gastric and a duodenal ulcer, his procedure depended on the nature of the gastric lesion: if it was a small ulcer he excised it and did a gastro-enterostomy: if it was big and adherent he did a partial gastrectomy. He always gave alkalis for three weeks after operation, and prohibited all smoking.

JOURNALS

Quarterly Journal of Medicine

THE April issue (Vol. III., No. 10) contains the following papers: Increased Carbohydrate Tolerance in Diabetics Following the Hourly Administration of Glucose and Insulin over Long Periods, by Arthur Ellis (London). It was noticed while treating a large number of diabetics that severe cases, mostly young subjects, requiring large doses of insulin, showed wide fluctuations in blood-sugar, marked hyperglycæmia occurring at certain hours, with hypoglycæmia at others. This instability was thought to be due to a depletion of the hepatic glycogen reserves and an attempt was made to increase these reserves by giving hourly glucose and insulin. Surprising results were obtained: first, in the amount of glucose which severe diabetics could deal with in these circumstances; secondly, in the temporary improvement in carbohydrate tolerance which resulted.—A Contribution to the Study of Erythroblasteris: Icterus Gravis Neonatorum, by J. C. Hawksley and Reginald Lightwood (London). An investigation was made into the part played by the blood and blood-forming tissues in this disease; the blood changes were found to consist, in a rapidly developing anæmia, of an hæmolytic type with a brisk response by the hæmopoietic tissues which were intensely stimulated. Evidence is given supporting the view that some cases of idiopathic juvenile cirrhosis and splenic anæmia may have their origin in icterus gravis.—Pellagra in Britain, by Hugh S. Stannus and Charles R. Gibson. A case of pellagra is described at length with a detailed history of onset, progress, and recovery, together with subsequent observation over a period of two years. The geographical distribution is discussed and this is followed by a summary of all the published cases in this country.—Observations of the Speed of the Circulation, by C. W. Curtis Bain. The normal time taken by the blood to travel from the arm to the face is determined by the histamine flush test. The time was found to be fast in hyperthyroidism, effort syndrome, advanced anæmia, and diseases of the lung. In cardiac cases dyspnœa and effort angina appeared when the flush time had slowed to 31 seconds and venous congestion was found in about half of those cases whose flush time was 32 seconds or more. Œdema was an almost constant finding in cases whose flush time was 42 seconds or more, the above figures applying only when the lungs, blood, and basal metabolism were normal.—The Peripheral Circulation in Acute Lobar Pneumonia, by C. Bruce Perry (Bristol). A study of the behaviour of the small vessels of the skin was made in 26 patients suffering from lobar pneumonia with the object of establishing that the circulatory failure in lobar pneumonia was a failure of the circulation at the periphery rather than a failure of the myocardium on the vasomotor centre. It was found that the capillaries of the skin showed *an impaired efficiency* in their contractility at the height of the disease and that their recovery was slow and was not immediately affected by the crisis. It was concluded that part at least of the circulatory failure in lobar pneumonia was due to this inefficiency of the small blood-vessels. It was further established that the blood pressure was raised rather than lowered during the acute phase of the disease.

REVIEWS AND NOTICES OF BOOKS

Pulmonary Tuberculosis

Medical and Surgical Treatment. By H. MORRISTON DAVIES, M.D., M.Ch., F.R.C.S., Medical Superintendent, Vale of Clwyd Sanatorium, Consulting Surgeon to University College Hospital. With Chapters on Specific Treatment by L. S. T. BURRELL, M.D., F.R.C.P., Physician to the Royal Free Hospital and the Brompton Hospital for Consumption and Diseases of the Chest; and Tuberculosis in Childhood, by W. BURTON WOOD, M.A., M.D., M.R.C.P., Physician to the City of London Hospital for Diseases of the Heart and Lungs. London: Cassell and Co. 1933. Pp. 460. 27*s*.

Mr. Morriston Davies occupies a unique position in this country, not only as a pioneer worker in thoracic surgery, in which connexion his name is as well known abroad as it is at home, but as one who for many years has combined the dual rôle of physician in charge of a sanatorium and thoracic surgeon. The combination of these qualifications in one man is rare, but obviously the physician-surgeon should be peculiarly well fitted to assess the value of treatment by ordinary sanatorium methods and the benefits to be obtained by more active intervention. Mr. Davies's constant insistence that the effects of expectant treatment at a sanatorium should be studied before surgical intervention of any kind is considered will command general approval; but when such methods have failed, the patient may well be prepared to accept immediate suffering and the risks inseparable from surgery in the well-founded hope that surgical interference may lead at any rate to a temporary restoration of health and some prospect of permanent cure. Special interest thus attaches to the author's descriptions of collapse therapy in all its forms. It is an achievement to have condensed so vast a subject into so small a space; less than 250 pages contain all that the general medical reader, and indeed almost all that the chest physician need know of every accredited surgical method employed in the treatment of pulmonary tuberculosis. The reader may feel that some of the operations described, involving three or even more visits to the operating theatre, would be a severe strain even on a phlegmatic patient, and that by the highly sensitive such recurrent mutilations, undertaken as they must be without guarantee of success, would be regarded as worse than death. It is indeed almost with a feeling of relief that we learn that some concession to human frailty is allowed when the position is at last admitted to be entirely hopeless and "it is time to relax some of the rigours of treatment." Mr. Davies's care for detail and therapeutic minutiæ of treatment are very apparent in his sympathetic references to the dying and in his suggestions for the alleviation of terminal suffering.

The golden mean is not easy of attainment. There are those, and even sanatorium superintendents are of the company, who yield to the spirit of defeatism, and rather than risk the death of a patient will incur no risks in treatment. But as Mr. Davies points out, though death from misadventure may thus be avoided, death from disease becomes inevitable. There are also those who lose sight of the ends in their enthusiasm for the means of treatment, and who appear to be more interested in experimental surgery than in the ultimate fate of individual patients. In the hands of the former group valuable lives which might have been saved are sacrificed to the timidity or even to the mental inertia of their medical advisers. But precipitate intervention or surgical interference in cases beyond the reach of surgery entails unjustifiable risks in the one case, and aggravation of suffering in the other. And lives are lost which might have been saved.

Dr. L. S. T. Burrell contributes a useful section on specific therapy, and Dr. Burton Wood has written an admirable chapter which describes and illustrates the various manifestations of pulmonary tuberculosis encountered in childhood.

We warmly commend this book, not only to the attention of special workers in this field, but also to the general practitioner upon whose advice as to the best methods of treatment the ultimate fate of the patient often depends.

The Teaching of Speech

By G. SIBLEY HAYCOCK. Stoke-on-Trent: Hill and Ainsworth Ltd. 1933. Pp. 302.

THIS book, issued by the National College of Teachers of the Deaf, is made up of three parts written at different times and approaching the subject from different angles. The first section, on the methods for promoting the quality of naturalness in the speech of the deaf, is the Braidwood prize essay, awarded to the author in 1928. It is a clear description of the ways in which the teacher of the deaf may induce by cultivation a good voice, resonant, intelligible, and satisfactory as regards speech. The task of the teacher is particularly difficult when a pupil has to be taught to vary the pitch, and Mr. Haycock rightly points out that in all the methods which he suggests the teacher, besides being experienced and possessing a good ear and technical knowledge of the rules of voice production, must have imagination and ingenuity. The second section of the book is a classification of speech sounds with an explanation of their production and development. The common faults of voice production are stated as well as the methods for their correction. The directions given are precise and elaborate; even when labial and dental adaptation are required the author's instructions can be followed. The third section deals with the maintenance of intelligibility and contains practical suggestions as to how intelligibility may be promoted throughout a school career. An interesting addendum to the first section is a note on the value of suggestion in the development of pitch in the voice of congenitally deaf children. The child possesses a larynx and all the accessories for supplying motive power and for increasing the volume and resonance of the laryngeal note, but cannot produce markedly different tones. The only way out of the difficulty, says the author, is for the teacher to act on behalf of the child and devise suitable exercises for the evocation of tones. Then, and with great perseverance, he must proceed on the principle of trial and error instructing the pupil to reject the bad results and hold fast to the good.

Mr. Haycock, who is superintendent of the Langside School for the Deaf in Glasgow, has for many years been recognised as one of the foremost teachers of the deaf not only in England but in all civilised countries, and it is good that he should have placed his range of practical knowledge at the disposal of those concerned.

THE LANCET

LONDON: SATURDAY, APRIL 28, 1934

THE DIFFERENTIATION OF NOXIOUS DUSTS

THE medico-legal significance of dangerous dusts in industry is beginning to assume the international importance which it has long deserved. Following the report of a committee of experts convened last year, a meeting of representatives of governments is to be held at Geneva next month with the object of drawing up a preliminary charter to secure compensation for those who suffer damage due to silicosis, one of the most generally recognised forms of hazard. It is unlikely that asbestosis, another scourge whose evils have been demonstrated more recently, will as yet be granted international status. The sequence leading up to such recognition usually begins with private action—i.e., admission by a firm or group of firms conducting an industry that the workers in it are liable to a risk. This admission is sometimes made spontaneously and sometimes under pressure of local public opinion, and is generally associated with research into the methods whereby the risk can be reduced or avoided. There follow regulations for the protection of persons employed in the hazardous occupation and a scheme of compensation for those affected in proportion to the damage they have suffered. The next stage is the coördination of such schemes in any one country by laws designed to bring the practice of all employers up to the standard set by the best, coupled, as in South Africa and in this country under the Medical Research Council, with active encouragement by subsidy of research into the cause and possibilities of prevention and cure of the pathological condition engendered by the dust. Only when national conscience in several countries has reached a certain degree of sensitivity can international action be hoped for. This stage has now been reached in regard to silicosis, but it is clear that other allied conditions will demand recognition in the future.

In the past the only way of establishing the dangers of inhaling any particular dust was the melancholy one of observing the toll of morbidity and fatality among the workers exposed to it. No criteria could be established in advance of this experience, since the fibrotic process is as a rule slow to develop. The obvious method of study—the exposure of animals to the dust under the same conditions as the workers in mines and factories, or the mimicry or exaggeration of such conditions in specially constructed dusting chambers—has been used by Dr. L. U. GARDNER and his staff at Saranac Laboratory for many years with success, and it is evident from his report for 1933, which has just reached us, that development of this work on a vast scale is contemplated. This technique, however, has the primary disadvantage that the length of time during which exposure is necessary is so long as to be measured in years rather than in months. There is need for more rapid methods of distinguishing potentially dangerous from inert dusts in order that the risk may be recognised before serious damage has been done, and adequate means devised and adopted for the protection of workers exposed to the dust. Incidentally it is highly desirable to investigate biologically the theory recently put forward by Mr. W. R. JONES, D.Sc.,[1] that the presence or absence of sericite—a silicate of potassium and aluminium—in a dust is the factor determining its pathogenicity. His view is based on his detection, by petrography and by chemical analysis, of the presence of sericite in lungs of patients dying from silicosis and his failure to detect this substance in lungs of men dying from fibroid tuberculosis of the lung who have not worked in a dusty atmosphere. His conclusions are supported by the fact that in certain mines in Australia, and in the Kolar gold mines in India, where silicosis is unknown, no sericite is present, whereas in the Rand mines of South Africa it is present in large proportion. If Dr. JONES proves to be right it will be necessary to establish the proportion of sericite that makes a dust dangerous. Thus for many reasons a more humane method of diagnosing dangerous dusts than by watching the fate of employees, and a more rapid and certain method than by the use of a dusting chamber for animals has long been desired.

In a series of communications bearing on this problem published during the last two years Prof. E. H. KETTLE has described experimental methods which in his hands have proved more convenient than dusting chambers for the differential diagnosis of biologically harmful from biologically inert dusts. Of these, the first to be tried was the subcutaneous injection of a suspension of the dust to be tested into the flank of a mouse, which subsequently receives an emulsion of tubercle bacilli into the tail vein. Dusts which are known to be active cause local necrosis and a pronounced cellular reaction in which the tubercle bacilli accumulate and multiply; while the inert dusts bring about little or no tissue reaction and do not favour the growth of the bacilli. A drawback of the method is the production of lesions in the subcutaneous rather than in the pulmonary tissues where the damage occurs in industry, and in recognition of this the next step[2] was an attempt to expedite the formation of pulmonary lesions by intratracheal injection of suspensions of dust. The onset of fibrosis was disappointingly slow, so slow indeed as to raise a doubt whether in the absence of an infective factor it is possible to produce silicosis. When, however, a suspension of even an avirulent strain of tubercle bacilli was introduced with the dust, the reaction to the infection tended to be so pronounced as to mask the early fibrotic changes due to the dust. An emulsion of killed tubercle bacilli was then substituted[3] for one of live bacilli, with the gratifying result that using the active dusts the fibrotic process was accelerated, while the inert dusts remained quiescent in the lung substance or were gradually phagocytosed. A further development of this technique is recorded in our present issue, which promises to provide a neat short cut to the classification of dusts. Where a noxious dust reaches the lung through inhalation or through intratracheal injection, the first lesion to be observed is in the glands at its base. As early as three months after intratracheal injection of a suspension of crystalline silica, or of finely ground flint, changes can be observed in the pulmonary glands, long before true silicotic lesions in the lungs are visible; but that these ultimately develop was shown by the examination of other animals in the same series which were allowed to survive for much longer periods. Control experiments with iron-coated silica and wellingtonite, both being inert dusts, showed merely a copious deposition of dust without any cellular activity or fibrosis. Since these observations were only incidental to the main object of the experiments, which was the study of the later pulmonary lesions, the earliest date in which the changes can be found was not ascertained. But it is clear that in the short space of three months or less it should be possible to estimate whether any given dust is likely to be among the active or inert dusts, though it is not claimed that a dust can be finally incriminated on indirect observations. Application of the method on a large scale might well result not only in a definite preliminary classification of dusts, but in the establishment of standards by which any samples could be tested.

AN AMERICAN HEALTH INSURANCE SCHEME

ONE effect of the profound economic depression in which the American people have been engulfed during the last three years has been to direct the attention both of the lay public and the medical profession to the subject of health insurance, which has hitherto been regarded as unsuited to American conditions and to the national character. The diminution of income from which all classes have suffered has been felt with special severity by those who earn their living by the provision of medical care. In 1930 the average income of doctors fell to 10 per cent. below the level of 1929, the last of the boom years, when in spite of the boom one-third of all doctors had net incomes of less than £500 and one-half less than £760, and the subsequent decline has been much more marked. In some parts of America, and particularly in the West, the troubles of the profession have been intensified by the growth of systems of contract practice carried on as commercial undertakings, in which the services of the doctors are exploited to their detriment for the profit of the lay promoters. These systems had their counterpart 40 years ago in this country, and they exhibit all the evils then described by a special commissioner of THE LANCET (the late Mr. ADOLPHE SMITH) in a remarkable series of articles, afterwards republished in "The Battle of the Clubs," which embodied the results of the first systematic study made of contract medical practice in Great Britain.

Health insurance, then, has already made its appearance in America and seems likely to extend; and many doctors are seriously concerned that its extension should proceed on lines that will lead to results satisfactory both to the profession and to the public. The subject was discussed at the annual convention of the Western Hospital Association at Sacramento on April 9th–13th, which opened with an address on Health Insurance for the American People by Mr. JOHN A. KINGSBURY, secretary of the Milbank Memorial Fund. Mr. KINGSBURY outlined a scheme of compulsory health insurance, organised on a state-wide basis, which would apply to all families with annual incomes of less than £600 or £1000, and be open to voluntary contributors without income limit. The scheme would provide a complete range of medical services including hospital treatment, periodical medical examinations, dentistry, home nursing, prenatal care, laboratory services and immunisations, but no provision would be made for cash benefits to compensate for loss of wages. Mr. KINGSBURY is satisfied that it is possible to frame a scheme of compulsory health insurance which would be within the means of the public and yet pay the practitioner adequate remuneration. The scheme proposes to pay the general medical practitioners an annual sum equivalent to 30*s.* per insured person, the method of remuneration being settled by the organised group of practitioners in each area. It is estimated that the medical services would cost about £5 4*s.* per person annually, of which 20 per cent. would be borne by the State and the remaining 80 per cent. by insurance contributions graduated according to ability to pay. The scheme contemplates that while financial and administrative matters would be dealt with by an executive body the professional services would be under professional supervision, with a joint committee of lay and professional members to deal with complaints and disputes.

The administration of the scheme would be guided by what Mr. KINGSBURY regards as five practical lessons which emerge from the study of European and American experience. These are, in his own words:

> "1. Freedom of all competent practitioners who subscribe to the necessary rules of procedure to engage in insurance practice.
>
> 2. Freedom of all persons to choose their physician or dentist from among all practitioners in the community who engage in insurance practice.
>
> 3. Freedom of insurance practitioners to accept or reject patients.
>
> 4. Minimum interference of the insurance system with the private practice of medicine for those who prefer and can afford the private purchase of medical service.
>
> 5. Professional control of professional personnel and procedures."

It will be interesting to note the reaction of American doctors to Mr. KINGSBURY's proposals. Their official journal has recently remarked[1] that "American physicians have become accustomed to seeing the effects of compulsory health insurance depicted in a roseate hue," and has quoted at length a passage from our own columns [2] describing the hardship arising from the 10 per cent. cut on the 9s. capitation fee—a hardship now fortunately in process of mitigation.

THE CURRICULUM

At its Dublin meeting the representative body of the British Medical Association received and discussed a report from a special committee on medical education. The report was an interim one; the meeting was not asked formally to approve it but rather to indicate whether there was any fundamental objection to the main suggestions contained in it. That report was gratefully received by the meeting, and during the winter the same committee has continued its deliberations and has now presented [3] a report to the council of the B.M.A. which is to be submitted to the Bournemouth meeting in July for its approval, with the intention then of sending copies to the General Medical Council and other bodies interested in medical education. The interim report has been embodied in the report now presented. No alteration has been made in its main points; it has been rounded off and amplified.

Sir HENRY BRACKENBURY summarised the report at the Dublin meeting. The committee, he said, had defined medical study as properly beginning at the point at which a student starts work upon human anatomy and physiology, and they had had to decide what stage he should have reached before he began those studies. All agreed that the course should not be lengthened, but it was generally felt that the education of the student should have reached a certain standard before he entered on the study of anatomy and physiology, and the first main change proposed by the committee was that the student should give evidences of a heightened educational standard and of being well grounded in the fundamental principles of chemistry, physics, and biology in their application to medicine. Conflicting views have been expressed as to the nature of the instruction in the basic sciences necessary for medical education. There are those who emphasise the acquirement in physics, chemistry, and biology of a certain knowledge of facts which are of direct value to the medical student and practitioner, but the view has prevailed in the committee that the essential purpose of these studies is the training of the student in scientific method and discipline rather than the acquirement of a smattering of technical knowledge. If, as is suggested, two years or thereabouts are given to the study of these sciences along with other subjects of general education—usually English language and literature, a foreign language, and perhaps history—an intellectual equipment and scientific outlook will have been acquired which will enable the student readily to apply these sciences to his own particular field.

After registration, which the committee would wish to see made a statutory obligation, it is felt that too great demands are made on the student's time in the courses of anatomy and physiology as at present taught. These should be taught as interrelated subjects, their main aim being the study of the living rather than the dead body, and it will be generally admitted that it cannot be necessary for the student to dissect every part of the dead body. At this period it is suggested that the student should become familiar with the methods of manual examination and be taught the use of the clinical thermometer and the various "scopes" along with the estimation of blood pressure, the examination of blood, and the analysis of secretions; but not more than five terms should be occupied with this part of the curriculum, and in its present report the committee shows how desirable it is for the inclusion of three special subjects, attention to which has been woefully inadequate. These are genetics, growth, and mental function—and although from the systematic side they could probably be dealt with in a few lectures the committee evidently doubts whether these should be given by the appointed teachers of anatomy and physiology. The most interesting suggestion for the clinical years is that a period of two years and six months on the lines of the present curriculum, but with less specialisation, should close with the final written and oral examination, but that the student should not be eligible to obtain his legal qualification without a further period of nine months of practical experience to be gained in one of five ways: (1) in a resident appointment in a teaching hospital; (2) as clinical assistant in a hospital or clinic; (3) as pupil assistant to an approved general practitioner; (4) as pupil to an approved M.O.H.; (5) in regular attendance at hospital practice in a medical school. It was at this point that the committee was not unanimous, for one of its members felt that it was a bad thing for students to spend their last year hanging about the hospital out-patient department. The report as it stands is a very interesting and stimulating contribution to the revision of the medical curriculum which does at long last seem likely to be taken seriously.

THE council of the British Medical Association has recommended that Sir Richard Stawell, consulting physician to the Melbourne Hospital and Children's Hospital, should be elected president of the Association for 1935–36. The annual meeting is to be held at Melbourne next year in the week beginning Sept. 9th, and at Oxford in 1936. The report of the council issued last week states that the Sir Charles Hastings clinical prize for 1934 has been awarded to Dr. Helen Lukis, of New Malden, for her study of the problems of anæsthesia in general practice. The Katherine Bishop Harman prize given every second year for the encouragement of study and research in avoiding the risks of childbearing has been awarded to Dr. J. M. Munro Kerr, regius professor of midwifery in the University of Glasgow. A certificate of honourable mention was given to Dr. Dora Colebrook.

ANNOTATIONS

VITAMIN-A DEFICIENCY

LACK of vitamin A produces its worst effects in infancy, when it may cause blindness from keratomalacia. A lesser deficiency is associated with xerosis of the conjunctiva with night-blindness; and when it is yet milder there may be night-blindness with no other ocular symptom. The proposal is now made that moderate degrees of vitamin-A deficiency should be ascertained by testing the light sense, and working in the pædiatric and orthopædic divisions of the Children's Hospital in Iowa City, Dr. P. C. Jeans and Dr. Z. Zentmire [1] have examined this in 213 children who were considered to be in normal health. For the purposes of the test a Birch-Hirschfeld photometer was used and it was found that 168 of the children had normal recovery of light adaptation after 10 minutes in the dark. The other 45, however, had an abnormally slow recovery, and to discover whether this depended on a deficiency of vitamin A 21 of them were retained in hospital. Here it was found that after periods varying from 4 days to 6 weeks (average about 12 days) on a diet ncluding three teaspoonfuls of cod-liver oil daily they all showed normal response to the dark-vision test. These figures suggest that about one-fifth of all the children tested had some degree of vitamin-A deficiency, and though they were to some extent a selected group, being physically afflicted members of poor families, Jeans and Zentmire have clearly made out their case that moderate degrees of night-blindness in children are not uncommon, may pass unrecognised, and can readily be detected and cured.

The whole subject of vitamin-A deficiency in children is reviewed in a very helpful way by Dr. Helen Mackay in the April number of the *Archives of Disease in Childhood*. After quoting G. A. Dawson's observation that in 1928–29 there were about 100 cases of night-blindness and xerophthalmia attending nursery and elementary schools in Darlington, she goes on to mention observations of her own which suggest that slight grades of deficiency are also common in nfants. These observations (to be fully described n the next issue of the same journal) concern the relation of such deficiency to the minor infections of the skin so often seen in children of the hospital classes. Though in Mackay's opinion there is no satisfactory evidence that lack of vitamin A is responsible for any of the usual respiratory or intestinal infections of children in this country, she has come to regard susceptibility to skin infections as "probably the first sign of vitamin-A deficiency in infants." It is possible, she adds, that the relatively high incidence of such infections in the lower social strata is more a matter of diet than of soap and water.

INFECTION AND DENSITY OF POPULATION

General R. Erhardt, of the Swedish Army Medical Service, has recently [2] drawn attention to the effects of density of population on the incidence of certain diseases such as angina faucium and streptococcal infections in general. In 1910, 75·2 per cent. of the Swedish population lived in rural areas. By 1930 this ratio had fallen to 67·5 per cent. It is probable that this tendency of the Swedes to collect in the towns is reflected in the frequency with which angina faucium occurs in the Swedish army. Between 1921 and 1930 approximately 17 per cent. of all the illnesses in the Swedish army belonged to this category. Incidentally the same disease takes first place among Finnish recruits, and it has been calculated that more than 50 per cent. of all the deaths in the Finnish army are due to streptococcal infections. Dr. Erhardt draws special attention to recent changes in the concentration of his fellow-countrymen in hospitals and allied institutions. While the total population of Sweden rose from 5·3 millions in 1907 to 6 millions in 1927, the number of general hospital beds rose in the same period from 8580 to 18,085, the number of sanatorium beds from 892 to 6309, the number of fever hospital beds from 3593 to 6962, and the number of mental hospital beds from 6898 to 12,118. This enormous rise in the number of institutional beds has been accompanied by an even more striking rise in the number of persons employed by hospitals and allied institutions. Taking a certain typical military hospital, Dr. Erhardt shows how, between 1910 and 1930, the number of persons employed on the hospital staff has risen from 30 for every 100 beds to 53. Dr. Erhardt discusses at considerable length and with the aid of charts the structural modifications he would like to see introduced by hospital architects with a view to minimising as much as possible a concentration of human beings which promotes infection.

A FÜLLEBORN MEMORIAL NUMBER

THE Tropical Institute at Hamburg is the abiding memorial of Friedrich Fülleborn but, as we have already indicated,[1] his pioneer work was in helminthology, and it is proper for a special parasitology number of the *Chinese Medical Journal* (November–December, 1933) to be dedicated to him. Among its many papers the filarial group of worms is well represented. L. C. Feng describes a new investigation into the differences between *Microfilaria bancrofti* and Brug's *Mf. malayi*, the material coming from Huchow, in the Chekiang Province; he speaks highly of methyl-green pyronin as a simple, lasting stain with good differential characters. It merits comment that though this embryo has been known for seven years no serious effort has been reported to find the adult worms by excision of glands during life, a method which has given such happy results in F. W. O'Connor's hands, and seems capable of modification to admit of the escape of the worms themselves for ready examination. S. M. K. Hu has shown, in collaboration, how ready an intermediate host is *Culex pipiens pallens* for *Wuchereria bancrofti*; and H. F. Hsu and J. Y. C. Watt that guinea-worm is indigenous in dogs in Peiping, and that four species of cyclops there are effective intermediate hosts, so that the causes of the happy escape of man merit investigation. R. Hoeppli is entertaining in a paper dealing with many curiosities in human parasitology. There was, for instance, an old belief in Europe that parasites were present as eggs when Adam and Eve were in Paradise, but that development was stayed till the eating of the forbidden fruit; there was a notion 150 years ago that tapeworms are disturbed by music; and there was the almost equally old comment that pains must be taken to discover the kind of instrument which they most dislike so that it might be used as a vermifuge. Among many facts which cannot at present be explained is placed microfilarial periodicity, it being noted that O'Connor's laborious and areful work speaks for Clayton Lane's theory that t is due to simultaneous cyclical parturition of the emale worms; but more work on this matter is eeded. There are several papers dealing with issue changes caused by parasites, for instance, umour growth and those caused by kala-azar and *Clonorchis sinensis,* the last furnishing yet another nstance where the extent of microscopical damage utstrips the appearance of clinical symptoms.

[2] Nordisk Medicinsk Tidskrift, Feb. 10th.

[1] THE LANCET, 1933, ii., 712

Finally, Hoeppli furnishes a sympathetic appreciation of Fülleborn. An army medical officer (he was wounded on the Western Front during the Great War), he was naturalist, helminthologist, and brilliant lecturer, had curious and complete incapacity to draw and a literary style which was complicated; he was a great conversationalist, fine cook, and persistent smoker—a many-sided and very human personality.

DAWSON WILLIAMS MEMORIAL PRIZE

THE Dawson Williams Memorial Fund was established by voluntary subscription in 1928 in commemoration of the late Editor of the *British Medical Journal.* Its object is the award of a prize every two years, or at longer intervals, in recognition of work done in connexion with pædiatrics. The fund is administered by the following trustees: the Presidents (for the time being) of the Royal College of Physicians of London, the Royal College of Surgeons of England, the British Medical Association, the Royal Society of Medicine, and the Section for Disease in Children of the Royal Society of Medicine, and the Editor of the *British Medical Journal.* There have been two previous awards of the prize—namely, in 1930 to Dr. F. J. Poynton, for his work on behalf of rheumatic children, particularly with regard to the establishment of special "rheumatic centres"; and in 1932 to the late Sir Robert Jones for his work in connexion with the pædiatric side of orthopædics. The trustees have decided to make the third award this year to Dr. G. F. Still in recognition of his work for sick children, and with the consent of the council of the British Medical Association the prize (a certificate and cheque for 50 guineas) will be presented by the President of the Association on the occasion of his presidential address at Bournemouth on Tuesday, July 24th, 1934.

VOMICÆ TREATED CONSERVATIVELY

BEFORE the Medical Society of Davos Dr. F. Bauer has related his experience[1] of the spontaneous disappearance of tuberculous cavities in the lung. Speaking after long residence in Alpine sanatoriums Dr. Bauer has retained his belief in the ability of the hygienic-dietetic régime to deal with the severe destructive forms of tuberculosis of the lung, and he besought his colleagues not to forget the wonderful successes attained before the introduction of collapse therapy—results still within the clinician's reach. For himself he could not overlook the troublesome complications resulting from artificial pneumothorax; patients who had recovered after collapse therapy did not, he thought, regain respiratory function as completely as those who had not undergone any surgical procedure. Dr. Bauer is a warm supporter of the standpoint of Dr. Fernand Cardis of Leysin, who demands a period of strict conservative treatment lasting two or three months before beginning pneumothorax treatment. Even with afebrile patients he thought this period was best spent in absolute rest in bed. It should be long enough to show whether there was a good tendency towards fibrosis. In any case it gave time for a diminution of toxic absorption and for improvement in the condition of the remaining foci in the same or in the other lung. He thought the danger of hæmoptysis during this period had been very much exaggerated; he had very rarely seen it occur. The likelihood of the pleura becoming prematurely adherent—the other objection raised—was very slight in patients kept strictly quiet in bed. Recently he had occasion to inquire again into the subsequent history of the 29 patients with lung cavities, treated conservatively in the Park (late Turban) Sanatorium, reported on by H. Wohlers[2] four years ago; 21 of these patients now, after an average period of six years, had remained well, 18 of them following their normal occupation.

OPTICAL CRAFTSMEN

THE last day of the recent London meeting of the Ophthalmological Society of the United Kingdom was taken up by a tour of inspection of optical workshops. The Association of Dispensing Opticians had extended an invitation to the society to inspect two of the larger factories owned by its associates. These two firms were obligingly at work over the Saturday afternoon in order that the congress members might see in progress the various processes in the manufacture of spectacle lenses, safety glass, frames, and ophthalmic instruments. In these days of mass production the visitors must have been refreshed by the extent to which this work remains a craft. It is true, of course, that the ophthalmologist's prescription is translated by the technical and mathematical lore of a generation into precise instructions to a machine, but even so the man or woman in charge of the machine has enough scope to take pleasure in the work. The materials themselves are attractive, consisting primarily of optical glass, emery, and rouge; the addition of pitch with which the lens is fixed firmly into its bed before grinding begins affords additional pleasure owing to its plasticity to the younger members of the staff who use it. It must often have occurred to the unlearned to wonder how an optical prescription which may contain both cylinder and prism, as well as two spherical surfaces, can be readily and precisely translated on to a spectacle glass. It is interesting to know that where bifocal glass is ordered the work always begins with differentiating between these two spherical surfaces, the deeper of which is first ground and then filled in with some protective material while the flatter surface is ground. When this has been completed the lens is taken out of its bed and turned over to take the rest of its grinding on the other surface. Checking of the curvatures requires instruments of extreme precision, and these are for the most part designed and made in the same workshops. The transparency of the working material has this advantage, that instruction about the axes of the cylinder can be affixed with white cement to the surface of the glass which is not being worked at the time, and the white letters stand out vividly against the background of pitch. There must be little or no occupational risk, as the grinding is all done on a wet surface; in the only department in which the lenses are clipped to shape the workpeople wear protective masks. The material for frames also affords much scope for craftsmanship, especially in working the shell of the turtle, which still remains the most popular frame in use in spite of the growing variety of more plastic and less expensive materials. The only regret in the ophthalmologist's mind must be that the refractive error and the eye for which it is prescribed are not susceptible to as accurate an analysis as the spectacle glasses; in fact, compared with the product of the modern optical workshop the eye itself is becoming a little démodé.

INTRACRANIAL TUMOURS

A RECENT analysis by Dr. Leonard B. Cox[1] of a series of 135 cases of intracranial tumour collected in Melbourne, shows that the same types occur in much the same numerical proportions as obtain both in this country and in the United States. An exception, however, is found in granulomatous tumours, which are much rarer in Victoria. Cox's series does not include any of these tumours; they form 2·2 per cent. of Cushing's much larger series and were undoubtedly far more frequent, in this country, at any rate, during last century. The difference is attributed to the greatly lowered incidence of tuberculous infection in Australia and to the more efficient prophylactic and hygienic conditions of the present day. Most of Cox's specimens were obtained at necropsy. This, no doubt, accounts for the fact that metastatic and invasive tumours form 14·1 per cent. of the total, whereas they formed only 4·2 per cent. in Cushing's collection, which is essentially that of a practising surgeon. There can be little doubt, from consideration of statistics published elsewhere, that the former figure gives a more accurate estimate of the incidence of secondary intracranial growths.

The gliomas are analysed at considerable length. Those who are interested in the cytological problems of this group will find a more detailed account in a previous article by the same author.[2] While adopting the classification of Bailey and Cushing and appreciating its value as a means of dividing the gliomas into groups having a definite clinical and histological picture, Cox is critical of its theoretical implications. He concludes that "a classification based on the similarity of the neoplastic cells to those observed in histogenesis does not present an exact picture of these tumours." Most histologists will agree with him. In practice a certain number of specimens present insuperable difficulties to classification. Amongst the different types of glioma that known as glioblastoma (or spongioblastoma) multiforme was most frequently encountered in the Melbourne series. This tumour arises as a rule in the deeper parts of the cerebral hemispheres and displays a highly malignant character. Cox, therefore, takes the reasonable view that the surgical removal of such tumours is in general impracticable. He lays himself open to challenge, however, in suggesting that such attempts are never feasible. It occasionally happens that a tumour of this type is small, superficial, and reasonably circumscribed. Such examples have been successfully removed, but it is not yet known with what ultimate results. The medulloblastomas, which occur principally in the cerebellum in young children, are also highly malignant and hence unfavourable from the surgical standpoint; they are, however, susceptible to X ray treatment. In the Melbourne series a few examples were found in adults, and evidence was obtained that in some of these the rate of growth is much slower than is the common expectation. The meningeal tumours, or meningiomas, lend themselves readily to surgical removal provided that vigorous measures are taken to prevent the exsanguination of the patient. Cox finds that recurrence of the tumour often takes place even when its removal was thought to be complete. This, again, is a point on which individual experience is likely to vary. These tumours are almost always histologically benign, and the factors that are responsible for recurrence are as yet little known.

Diagnosis of a metastatic tumour is generally a signal for inactivity as far as surgical intervention is concerned; some surgeons hold, however, that if the cerebral metastasis is solitary and accessible it may be worth while attempting its removal. Amongst other guiding principles on treatment Cox suggests that "in practice it is wise to do a decompression operation over the site where a tumour is considered to be growing, even if a pessimistic view be taken of its nature. . . . . By an examination of the exposed brain there is less chance of being confronted at autopsy by a favourable tumour where an unfavourable one was diagnosed. In each of two cases in this series, an operation for carcinoma had been performed prior to the onset of cerebral symptoms. It was expected that the cerebral tumours would be metastases, but in each case a glioma was found at autopsy." Even if the tumour should not be wholly removeable there are substantial chances both of relief to the patient and prolongation of his life.

THE PERILS OF THE MILK-SUPPLY

A DEPUTATION from the People's League of Health was received by Sir Hilton Young, the Minister of Health, and Mr. H. E. Dale, representing the Ministry of Agriculture, on Wednesday last, April 18th, the object of the deputation being to urge upon the Government the need for efficient protection of children from milk-borne diseases, and especially from the danger of contamination with tubercle. The deputation had its origin in the scheme of the Government for the provision of milk for children in State schools, and the speakers presented the difficulties under which medical practitioners laboured in advising the use of cow's milk with a knowledge that it was improperly controlled. The deputation having been introduced by Dr. C. O. Hawthorne, chairman of the Council of the League, Lord Moynihan emphasised the fact that the existing supply of milk, defined by him as "almost a perfect food" was not safe, and gave it as his opinion that, while the eradication of tubercle from cattle would lead to a safe supply, it was impossible to wait for such a reform; for the present all milk other than "Certified" and "Grade A" (tuberculin tested) milk should, he said, be pasteurised. Many representative speakers followed, pointing out the wide existence of milk-borne infection, emphasis being laid in more than one quarter on the fact that if pasteurisation is adopted the procedure should be carefully controlled. Practical evidence of its utility, however, was afforded by Sir Pendrill Varrier-Jones, Sir John Robertson, and others. The unhygienic methods of milk distribution in London and elsewhere came in for notice, and finally Miss Olga Nethersole, the founder of the League, read communications from unexceptionable authorities, all stressing the dangers of milk-borne disease. Sir Hilton Young pointed out to the deputation that they were preaching to the converted, while he dwelt on the importance of educating the public in regard to milk-supply. Here he recognised the influentially supported work of the League to be of the greatest value. He agreed that all possible steps to remove infection from herds must be taken, but allowed that for the present reliance must be placed upon further measures for the protection of the milk-supply. And he reminded the deputation that the Government were prepared to spend £750,000, spread over the next four years, in support of a campaign for securing a purer milk-supply.

SANITY IN A MENTAL WARD

THE Sheffield coroner recently held an inquest on a woman of 60 who died from uræmia in the mental ward of a public hospital. She had been transferred there because her doctor had given a certificate stating that she was of "unsound mind." He had been treating her for bronchitis, she had become delirious, and he had overlooked the renal condition. The coroner commented on the difficulties in lunacy law administration and seemed to imply that as the patient had uræmia as well as bronchitis her delirious condition might have been treated differently and not in a mental ward. With such a contention very few of those responsible for general medical wards would agree. Ideally it would be possible to have two wards in a general hospital in each large centre reserved for delirious and confused patients whose mental symptoms followed upon physical disease. The benefit of this in puerperal cases is obvious, and the arrangement might do more than satisfy the Sheffield coroner. It might, for instance, lead to general physicians and psychiatrists working in closer association; some general trained nurses would acquire greater acquaintance with some forms of mental disorder; and the medical students would have occasional opportunities of seeing acute psychoses without being wholly dependent upon journeys to distant hospitals. Such schemes could not be carried out simply. They entail easily recognised difficulties, but so far as the student is concerned the divorce of ordinary clinical experience from his acquaintance with acute psychotic and psycho-neurotic disorders leaves him unprepared for the exigencies of practice when at any time he may need to deal with them.

Other reflections are provoked by the coroner's remarks. Have we really reached a point at which we do not label as insanity any disorder to which physical causes contribute? Fortunately the idea long prevalent that the insanities stood apart from general medicine is displaced in the medical mind by the recognition that all the available information about the physical condition of the patient is germane to the question why his behaviour is what it is. The immediate denial of physical causation in a psychotic patient examined only once is no longer possible. Such a cause is recognised in the syphilitic psychoses and some other obscure agent *may* be present in other mental patients. If the coroner's remarks have stimulated both psychiatrists and general practitioners to hunt for physical determinants of abnormal behaviour they will do nothing but good. From the layman's point of view two aspects of the interrelation between the physical and mental can be observed. These are a tendency to ascribe all mental disorders to a physical cause, an opinion which will enable him to avoid any inquiry as to how far environment or earlier maladjustments have contributed to a psychosis. The other—almost an opposite—tendency is to regard the senile psychoses as comparable to the biogenetic disorders. Both opinions tend to confuse those who are seeking to assess the degree of hereditary taint. The first predisposes to an optimism which subsequent events too often nullify. The second tends to divert inquiry from the arterial changes accompanying senile psychosis when further investigation might reveal symptoms due to the removal of inhibitions and the previous behaviour pattern of the patient.

One final question. Are we to rest satisfied with the fact that a uræmic patient became delirious? Or must we not go on to inquire whether the delirium is a matter of blood-chemistry or of psychic structure or both? We do not know why one cardiac patient becomes psychotic whilst another with a severe degree of decompensation remains mentally stable. These and many questions like them await a serious answer. Mental heredity only satisfies a certain number of such cases. If the Sheffield incident arouses that closer association between general physician and psychiatrist which is a corollary of the coroner's remarks, further knowledge of prognosis and psychopathology should be forthcoming.

GENITO-URINARY SURGERY IN AMERICA

THE printed transactions of the American Association of Genito-Urinary Surgeons record the trend of thought in this important specialty. In Vol. XXVI. which has just reached us H. A. Fowler and J. A. C. Colston record their views on primary carcinoma of the ureter and primary tumours of the ureter respectively. The rarity of this condition is shown by the fact that the records of the Bradey Urological Institute comprising over 22,000 urological cases contain only three instances of primary tumours of the ureter. A survey of the literature on the subject shows that the vast majority of these are of epithelial origin and of the papillary type. Squamous-celled epitheliomata are rarer and are usually found in association with chronic irritation from stones or infection. The most valuable diagnostic sign is obstruction to the passage of a ureteric catheter followed by copious hæmorrhage, and the appropriate treatment nephro-ureterectomy.—J. F. McCarthy and J. S. Ritter write on bacteriophage therapy in genito-urinary infections. Their greatest successes were in 16 cases of staphylococcal septicæmia, of which six recovered. The writers consider that bacteriophage therapy is a valuable prophylactic measure in the prevention of kidney infections secondary to carbuncle or furunculosis, as well as a means of treatment of established infections of the urinary tract. They have devised special instrumental methods for direct intraprostatic administration as well as for injection into the seminal vesicles.—J. R. Caulk in discussing prostatic resection claims that the electro-cautery is a safer method of removing tissue than the high-frequency current. He bases this opinion on the fact that high-frequency current applied for more than a second may do considerable damage to the surrounding tissues to a depth it may be of over a centimetre. A point of practical importance that may be deduced from this is that it is advisable in carrying out prostatic resection to shift the scene of activity from one portion of the gland to another, in order to avoid accumulative heating of any one segment. Caulk urges that the smallest effective current should be applied for the shortest possible time and that if bleeding occurs it should be controlled with coagulation currents which are far less penetrating and damaging. In his opinion some of the cases of incontinence that have followed resection may be due to the devitalising action of heat on the sphincter.—Writing on the subject of bony metastases secondary to carcinoma of the bladder, R. C. Graves and R. E. Militzer state that these are more common than is usually supposed; apart from the pelvis, there would seem to be no particular predilection for any bone. Bony metastases from carcinoma of the bladder are usually of the osteoclastic type although some cases show osteoplastic changes.—G. C. Prather and E. C. Crabtree contribute an interesting article on the lone kidney in pregnancy, based on a total of 296 nephrectomised women and 365 pregnancies. Although the surviving kidney showed the dilatation changes in the pelvis and upper ureter that are so familiar in pregnancy, renal function tests proved the existence of an adequate margin of safety. Accumulated statistics give a mortality-rate of only 1·09 to 1·4 per cent., proving that as a general principle nephrectomy is not a contra-indication to pregnancy.

POST-OPERATIVE INFECTION OF THE PAROTID GLAND

MASSABUAU, Guibal, and Bert in a recent communication [1] distinguish two types of parotiditis occurring as a sequela to operation. In one, suppuration of the parotid is an incident in the course of a general pyæmia, and carries a very grave prognosis. Parotiditis developing during convalescence from a straightforward surgical procedure (such, for example, as appendicectomy and sub-total hysterectomy in the two cases quoted) usually runs a more favourable course, although subject to the danger of certain rather common complications. Of these the three most important are facial paralysis, temporomandibular arthritis, and perforation of the wall of the external auditory meatus. Facial paralysis is not usually due to direct injury either by the incision of the gland or by spreading gangrene in its substance, but, according to Massabuau, is caused by compression, or by œdema of the nerve sheath. It is a lesion from which a full recovery is to be expected, even though it may be a tardy one. The paralysis lasts, on an average, from three to six months. Temporomandibular arthritis may be further complicated by the supervention of subluxation of the joint. In a patient observed by Massabuau, in whom such a subluxation was associated with facial paralysis, there was what he calls "une physionomie très particulaire." Perforation of the anterior wall of the meatus seems to be a comparatively common complication. Raby, quoted by Massabuau, gives the incidence as 34 out of 100 cases. The pus appears to take the line of least resistance to the postero-inferior part of the gland and then to track through at the attachment of the cartilage to the bone. This perforation of the meatus becomes apparent about the tenth day of the parotiditis and does not seem to be of very serious import; it may occur despite early incision. Massabuau discusses the various theories of the ætiology of post-operative infection of the parotid. He holds that Stenson's duct is definitely inculpated as the portal of entry. Inflammation starts in the centre of the gland and is multipolar in spread, the peripheral parts being only secondarily infected. The flora of the infected gland is that of the mouth. Finally, experimental infection of the duct has been much more successful in producing parotiditis than has experimental infection of the artery of supply. Granted that the infection spreads from the mouth the incidence of the disease must be traced either to buccal infection (gingivitis, dental caries, stomatitis), to lowered general or local resistance, or to alteration in the excretory function of the gland. There would appear to be reasons to suspect several of these factors operating in any one case. Suppression of salivary secretion may be of importance, sometimes in relation to the absence of the normal stimulus when the patient is given fluids by routes other than the mouth. Various factors associated with operation, such as purgation, vomiting, hæmorrhage, and excessive secretion during ether inhalation, may deplete the patient of fluid and be followed by a diminished salivary secretion. The possibility of reflex inhibition has also been mooted. Passive congestion, as by lying constantly on one side of the face, or injury to the parotid by forceful traction on the mandible during anæsthesia have also been blamed. Treatment consists essentially in early superficial incision of the infected gland with opening of the deep part with forceps. Pus is not always found, but discharge is likely to appear in abundance within the following two days. Other forms of treatment proposed, as injections of pilocarpine, compression of the gland and bacteriophages, are generally regarded as of subsidiary importance.

THE PREVENTIVE ASPECTS OF MEDICINE

THE course of lectures on the preventive aspects of medicine which was held on Thursday afternoons during the winter session at King's College Hospital, and was open to medical men as well as to students, is to be resumed on May 3rd, when Col. L. W. Harrison will lecture on the Prevention of Venereal Diseases. Four subsequent lectures will be delivered to complete the series, on May 10th, 17th, 24th, and 31st, as follows: Prevention of Accidents, by Prof. Millais Culpin; Prevention of Mental Diseases, by Dr. Edward Mapother; Principles of Immunisation as applied to Preventive Medicine, by Prof. W. W. C. Topley, F.R.S.; and Public Agencies which exist for the Prevention of Disease, by Dr. Allen Daley. These concluding lectures, like their predecessors in the series, will be published in THE LANCET.

ON Tuesday, May 1st, and Thursday, May 3rd, at 5 p.m., Dr. C. H. Andrewes will deliver the Oliver-Sharpey lectures of the Royal College of Physicians of London. His subject is viruses in relation to the ætiology of tumours. Prof. O. L. V. de Wesselow's Croonian lectures, on arterial hypertension, are to be given on June 5th, 7th, and 12th.

POST-GRADUATE HOSPITAL COURSES IN SWITZERLAND.—The International Hospital Association is arranging a post-graduate course in Switzerland from Aug. 15th to 23rd, to be followed by a study trip through the canton of Grisons. The course is divided into three sections for which separate tickets will be issued. Section A opens with study committees at Basle on Aug. 15th, followed by hospital visits in Basle and Zurich on the 16th and 17th, and in Lucerne on the 18th. Section B opens at Berne on Aug. 19th with an official lunch followed by visits to local hospitals on the 20th and 21st, and a visit to Leysin where Prof. H. Rollier will receive on the 22nd and 23rd. Lectures will be given by well-known representatives of official bodies and hospitals, and a small scientific and industrial exhibition will be provided at Berne. Section C is a study trip on Aug. 23rd, passing through Brigue and Coire to Arosa where Dr. Gähwyler will lecture and Dr. Fonio demonstrate plans for a cantonal hospital; on the 26th Dr. Nienhaus will lecture at Davos; on the 27th Dr. Enderlin will talk at Schuls; and on the 28th the baths at St. Moritz will be visited under the conduct of Dr. Bernhard. Railway concessions have been obtained, and the cost of the course will not be greater than those of previous congresses at Vienna, Knocke, or Frankfort-on-Maine. The chairman of the International Hospital Association is Dr. G. von Deschwanden (Lucerne). Inquiries should be addressed to the Veska-Bureau, Obergrundstrasse 13, Lucerne, Switzerland.

PROGNOSIS

A Series of Signed Articles contributed by invitation

IV.—THE PROGNOSIS IN ENLARGEMENT OF THE PROSTATE

The Basis of Prognosis at the Initial Consultation

USUALLY it is an increased frequency of micturition which leads a man whose prostate is causing obstruction to seek advice from his doctor. Sometimes it is the dreadful pain of acute retention, at others the inconvenience of incontinence. Whilst the last condition demands without delay a surgical operation with its attendant risks, this is not necessarily true of the former. To take first the common case of bladder irritability, the gravity of outlook will vary within very wide limits. The practitioner must make the supremely important decision whether his patient's life will be curtailed by delay or whether, on the other hand, it may be possible to arrange that he may continue to pursue his usual avocations in safety, physical comfort, and mental repose. The primary consideration is the condition of the kidneys, and here may be emphasised the very great assistance to be obtained from the simple measurement of the residual urine. Should this be less than three ounces it is unlikely that renal impairment has occurred. But this opinion should be checked by information given by the amount of urea in the circulating blood and the urea-concentration test. If these are within normal limits the patient may be reassured. He need not face an operation. By careful living, by the avoidance of acts which cause congestion of the prostate he may live for some years with little or no discomfort and perhaps the necessity for operative treatment may never arise. On the other hand if the urine is infected, operation should be urged as the risk of extension to the kidneys is greater than the risk of surgical treatment.

To estimate the probable progress of the disease by the feel of the prostate per rectum is almost impossible. The hardness of the malignant prostate will reveal the inevitable steady increase in size, but many patients live for three or four years after a malignant prostate has first been diagnosed. With the soft adenomatous prostate, size is no criterion of the degree of obstruction. Indeed the central intravesical enlargement which early produces serious hindrance to urinary outlet is imperceptible by rectal palpation. In such cases of bladder irritability with impalpable enlargement, a cystoscopy must be performed to estimate the amount of obstruction or even the cause of it before any prognostic pronouncement can be made. The intravesical nodule causes so much obstruction that operation must usually be advised. Certain patients whose kidneys are unaffected, and whose residual urine may be no more than an ounce in quantity, suffer in health from the broken sleep due to great frequency. Operation with its attendant risks must be recommended in these conditions.

The man whose first symptoms are due to acute retention must be just as carefully examined when his acute condition has been relieved by catheterisation, before treatment can be planned or prognosis estimated. Curiously enough such patients sometimes come well out of such clinical scrutiny and with care may, without any discomfort whatever, continue their ordinary lives for a year or more before further symptoms arise. An attack of acute retention does not necessarily condemn a man to an operation. The outlook is dependent, as in the irritable bladder type, upon the damage which has or has not been done to the kidneys.

When the patient who presents himself is dribbling urine, with the bladder distended to overflow, serious renal deficiency is always present. These are the worst cases from that point of view, but on the other hand, power of recovery of kidney function is astonishingly great and in such cases the urine is seldom infected, so that the outlook is not too grave.

The Outlook following Surgical Operation

The immediate concern of a man about to subject himself to surgery as a relief for prostatic symptoms is his prospect of surviving the operation. Although within recent years careful preparation and selection has very much lowered the risk of prostatectomy, it must still be regarded as a hazardous procedure. The patients are generally old, frequently decrepit, their kidneys are damaged, their heart musculature enfeebled, they are often anæmic and have lost much of their powers of reaction towards infection. Taking into account all these unfavourable features it is truly remarkable that as low a mortality as 3·4 per cent. has been recorded in a large series of cases. The general mortality amongst expert operators is probably considerably higher than this, from 4 to 8 per cent. The mortality risk depends largely upon the condition of the patient when he seeks surgical aid. If there has been long-standing back pressure and infection has supervened the risk of death must be much greater, 10 to 20 per cent., whereas early in the disease it is certainly less than the average. Since the poorer members of society are apt to neglect the earlier signs of disease, hospital statistics are usually less favourable than those of series of private patients, though the conditions under which the former are operated upon are as good.

If it is decided that a two-stage operation is necessary because the blood-urea cannot be brought down to a reasonable figure by catheter drainage or because of serious sepsis, the practitioner must take a graver view of the case and not lose sight of the fact that the simple cystotomy of the first stage is attended with a distinct mortality. Yet even desperate cases, patients with a blood-urea of over 200 mg. per 100 c.cm., may be so restored to health by the preliminary cystostomy as to be able to negotiate the subsequent prostatectomy successfully, which may not be possible for many months: and it is probably true to say that the risk of the second stage is less than that of prostatectomy in one stage.

The principal causes of death after prostatectomy are uræmia, sepsis, hæmorrhage, and lung complications. Urinary retention can be remedied by adequate preliminary drainage, but some of the ill-effects of chronic uræmia are not so easily overcome. Patients who have had an original high blood-urea percentage seem more prone to infective complications, the two most serious of which are pneumonia and pyelonephritis. No amount of care in irrigation of the prostatic cavity left after prostatectomy would seem to protect them from some amount of infection in this situation, and it is apt to spread upwards to the kidneys. Serious hæmorrhage may occur even after simple cystostomy from rupture of a dilated vein in the mucosa of the bladder overlying the gland. Hæmorrhage is a menace at the actual nucleation itself for two reasons: it is not under complete control and the patients, owing to the renal changes, frequently have a lowered hæmoglobin content. An operation done on a patient with only 60 per cent. hæmoglobin is associated with a very serious risk. Hence the importance from the prognostic standpoint of making this estimation. If serious sepsis of the prostatic cavity occurs there is the subsequent risk of secondary hæmorrhage. Myocarditis increases this danger. Thickened vessels with low blood pressure and feeble heart sounds are of serious import.

The remote concern of the patient is with his ultimate condition of health. What prospect has he of his condition being one of betterment for all the risk he will have to undergo? In the first place he may be confidently told that his tenure of life, if he survive the operation, will certainly be longer than if he refuses surgical aid. And, secondly, he may be assured that in general health and well-being he will stand a very great chance of approach to the normal. That this claim can be substantiated is shown by all statistical investigations, the most recent of which (F. S. Crockett and W. W. Washburn) may be quoted.[1]

> One hundred patients were questioned. Ninety-three per cent. answered that their general health was better. As far as the difficulty in beginning micturition went, 91 per cent. complained of none; 9 per cent. had some, and a stone was found in some of these. Seventy-two per cent. had no dribbling; 19 per cent. a little after voiding; and 6 per cent. dribbling at all times. Frequency at night was not abolished in so great a proportion of cases. Only 36 per cent. had no nocturia, but 19 per cent. got up only once or sometimes not at all; 15 per cent. got up twice or less. When asked if the operation was worth going through for the benefits obtained, 95 per cent. said they were satisfied, and actually 99 per cent. said the effort was worth while.

It will thus be seen that many of these patients are restored to complete health. However, in a number it is difficult to get the urine free of infection and this may never be accomplished. Nocturnal frequency may well be due to this cause.

Stricture after prostatectomy is now very rare. A few cases of persistent urinary fistula occur. It is sometimes difficult to assign a cause for this. Sometimes it seems due to sepsis in the space of Retzius or even of the pubes; occasionally it has been cured by the removal of a diverticulum or calculus. The chance of a fistula is lessened if the bladder be opened as near its apex as possible. It is a rare complication.

A very troublesome and painful incident is the onset of *epididymitis*. This may follow the passage of an instrument, but occurs quite independently of such manœuvres, sometimes when the patient returns home. It may be quite serious, leading to gangrene of the scrotum and even death from sepsis. It seems to be preventable by ligation of both vasa deferentia.

Some of the poorer results of prostatectomy when frequency continues, sepsis remains, and difficulty of micturition recurs are due to the enlargement being malignant in nature. Not uncommonly a prostate is found to be carcinomatous only when a microscopic examination is made. If malignant disease is suspected and the surgeon believes that nucleation is possible, it should be proceeded with. Growth of a carcinoma of the prostate is often very slow. Three, four, or more years' survival with great amelioration of symptoms at least during the early part of this period is not unusual.

PERURETHRAL OPERATIONS

The place which perurethral operations should take, and the prognosis associated with them, is a little difficult to assess. Brilliant results in adenomatous enlargement as well as with fibrous obstruction have been reported in America and some very good results by surgeons in this country. Nevertheless, it must be confessed that the enthusiasm with which this procedure was welcomed by English surgeons at its introduction has waned. Difficulties from secondary hæmorrhages and in the control of sepsis are not easy to surmount, so that it is probable that the risk of the urethral operation for simple adenomata is not materially less than that of the open method. There is a tendency to restrict its use to cases of bladder neck obstruction and the malignant prostate.

SPECIAL ARTICLES

MEDICINE AND THE LAW

The Bath Murder Case

THE conviction of Hinks in the Bath murder case, upheld on appeal, was largely due to medical evidence, and the main ground of appeal was that the judge at trial gave too little attention to the scientific witnesses called by the defence. Pullen, 81 years old, was found dead last December in the kitchen of his house. Hinks, his son-in-law living with him, said he heard a noise, went into the kitchen and found Pullen lying on his left side with his head and part of his shoulders in the gas-oven; two overcoats, he said, were draped over the front of the gas-stove and the trays had been removed from the inside of the oven. Hinks said he pulled the old man out by the feet and found Pullen had an apron held to his mouth. He turned off the gas and telephoned for the police and the ambulance men, volunteering to them the statement "you might find a bruise on the back of the head if you look where his head struck the floor." Dr. Scott Reid, the deceased's medical attendant, was reluctant to believe the story. "I know old Pullen," he said to Hinks, "and I don't think he could have done this in the way you describe." The aperture of the stove was 1 ft. 1½ in. across; the coats had not been drawn inwards by the insertion of the head and shoulders. Was it suicide or murder? The defence contended that Pullen was physically a fine old man, a good eater and well nourished, able to dress himself except for putting on his collar and tie. He had nearly been gassed, it was stated, in 1926, and he used to speak of it as a pleasant experience; "when I go, I shall go like that." The prosecution, on the other hand, said he was "tottery," constantly falling down and unable to pick himself up, incapable of the mental or physical effort to coördinate the elaborate actions of this supposed suicide, especially in the time at his disposal that night. He suffered, it was argued, from progressive senile degeneration and there had been a great change in his condition in 1933 between May, when he made a will, and September when, on a question of his executing a codicil, it was decided that he was quite unfit to understand the testamentary act. Before July a male nurse and a female nurse were employed to look after him; in July they were dismissed and Hinks gave up his work to take charge of the old man.

The Court of Criminal Appeal found the verdict was not against the weight of evidence and that the alleged misdirections of the jury were unimportant. If the judge at trial had not dealt fully with the medical evidence for the defence, it must be borne in mind that this, the latest evidence to be given, would have been freshest in the jury's mind. There was adequate evidence of motive. The family solicitor had found that Hinks, who had then been married for a few months to Pullen's daughter, was selling some of Pullen's property at Dorking against his own advice. The solicitor had refused to negotiate a settlement of part of the old man's estate on Hinks and had taken steps to protect the property by securing the appointment of a committee in lunacy.

Plainly the most significant medical evidence was that of the medical attendant who knew better than anyone else the old man's physical capacity. Much time was devoted at the trial to the bruise on the back of the head. The prosecution said that chemical tests indicated that the blood in the bruise showed no trace of carbon-monoxide poisoning; therefore the bruise, a severe one, was inflicted before death. They offered no theory as to the weapon used, if any, but they said the bruise disproved Hinks's story, since it could not have been caused by the head dropping 6 or 7 inches on to the linoleum floor after the gas-poisoning. The defence contested the conclusions and the value of the tests made several days after death. This was the part of the medical evidence which, on appeal, was said not to have been appreciated by the judge at trial and not to have been adequately stressed by him to the jury. The main issue, however, was whether Pullen was capable of squeezing his head and shoulders into the gas-oven after the preparations described. The jury evidently thought he was not. A curious feature of the case was that, on the night before death, Hinks had said he found Pullen in his bath with his head under water and his face black. Medical help being summoned, the doctor did not quite accept the story as consistent with Pullen's condition. The defence said the incident showed that Hinks had no design of murdering his father-in-law. Perhaps an alternative theory would have been that Hinks was already busy with the illusion of suicide.

It is interesting to note that Pullen's death was fully examined by the Bath coroner, the inquest not being interrupted (under Section 20 of the 1926 Act) by the initiation of criminal proceedings in another court. This fact, suggesting that the police authorities did not at first regard the case as strong enough to take up, shows that the coroner's inquest has by no means spent its force as an instrument for the investigation of crime and the detection of the criminal. Since the case has ceased to be sub judice a Bath newspaper has published details of Hinks's previous career which, had they been known to the jury at trial, would certainly have been fatal to his prospects of acquittal. On the other hand the *Law Journal* has twice referred to the verdict and the result of the appeal with a certain misgiving. While agreeing that the judges had strong grounds for not interfering with the verdict of the jury, it observes that the verdict of a jury is not infallible. Too much attention, it considers, was paid to the probable cause of death, and too little to the improbable circumstances which may have been the real cause.

Marriage Annulled for Insanity

Although the subsequent insanity of husband or wife is not yet a ground for divorce, the law will annul a marriage if either of the parties was insane at the time of the ceremony. This is because marriage is a contract and, as the court observed long ago in the Earl of Portsmouth's case, "the very essence of that most important engagement is consent; without soundness of mind there can be no legal consent." Last week Mr. Justice Bateson annulled a marriage on the petition of the husband, who alleged his own insanity at the time of the supposed contract. He had, it was proved, been mentally unfit for several months before October, 1932, when he went from Manchester to Nottingham and met a woman whom he had known for some time. They agreed to marry and were married next day by special licence. The pair went back to Manchester and lived together for a few days; a fortnight after the wedding the husband was admitted to a mental hospital. On eventual discharge from the hospital he remained under treatment and was now sufficiently recovered to be able to understand his petition though not yet fit to give evidence. The judge had to apply a test formulated in 1825 in Durham *v.* Durham: "was there a capacity to understand the nature of the contract and the duties and responsibilities which it creates?" Mr. Justice Bateson said the doctors had satisfied him that the petitioner might very well be, and in their opinion was, incapable of understanding what he was doing when he went through the ceremony of marriage; he was insane at the time and in the circumstances the marriage was a nullity and must be so pronounced.

The petition last week was more successful than that of the Earl of Durham in the case already cited. The Earl called three doctors to describe the mental state of Lady Durham, who after marriage became manifestly insane. The judge, Sir James Hannen, took into account her present condition, and asked himself if it was recent and sudden or whether it had been of slow growth and had already existed at the date of the marriage so as to invalidate the contract. He came to the conclusion that Lady Durham's mental illness did not exist until a visit she paid to Cannes after her marriage. The Earl's petition was therefore dismissed with costs. In the Portsmouth case the marriage was pronounced void because, though the husband was weak-minded rather than insane, there was an element of something like fraud in the conduct of other parties. The Earl of Portsmouth was brought up to London in 1814 by his medical attendant and was delivered over to his trustees, one of whom was Harrison, the family solicitor. A week later the Earl was married to one of Harrison's daughters; it was a clandestine wedding between a man of weak and deranged mind and the daughter of his trustee and solicitor. No such suspicious circumstances were present in the case decided last week, where the medical evidence was found sufficient to make the contract void *ab initio*.

IRELAND

(FROM OUR OWN CORRESPONDENT)

THE CUTS IN MEDICAL SALARIES

THE Temporary Economies Bill, affecting the salaries of the officers of local authorities, underwent a radical change last week in the Senate. Sir Edward Coey Bigger, formerly medical member of the Local

Government Board, introduced an amendment which provided for the exclusion from the scope of the Bill of all medical officers. Several senators supported him, and no one spoke against the amendment except the Minister in charge of the Bill, who gave as his principal ground of opposition that he did not like putting any one class of officers in a privileged position. He did not suggest that the present salaries were too high, and he agreed with other speakers that the dispensary medical officers had rendered, and were rendering, good service to the public. Although an identical amendment had been rejected in the Dáil the Senate adopted the amendment by 22 votes to 12. The only other amendment made by the Senate was a simple consequential one. The Bill as amended will now be returned to the Dáil which can agree or disagree with the Senate. Its action will depend largely on the attitude which the Minister may adopt. Hitherto he has not appeared to be over-enthusiastic for this particular clause of the Bill, and it is hoped that he may consent to the Senate's amendments, and leave the interests of medical officers uninjured.

THE IRISH MEDICAL ASSOCIATION

The annual meeting of the Irish Medical Association will this year again be held in Dublin, probably in the last week of June. In future years it will be held alternately in Dublin and the provinces. It is intended this year to widen the scope of the annual meeting by including a scientific session as well as a business section. Arrangements are being made to hold two scientific discussions on matters of interest to general practitioners as well as to physicians and surgeons. The association is reviving an old custom—unobserved since before the war—of holding a dinner on the evening of the annual meeting. It is understood that the present president and vice-president, Dr. Robert J. Rowlette and Mr. Charles J. MacAuley respectively, have consented to accept nomination by the council for another year of office.

MEDICAL ORGANISATION IN THE IRISH FREE STATE

At many times in history the question has been mooted of a unification of medical organisations in Ireland by the amalgamation or coördination of the Irish Medical Association with the British Medical Association. It has often been pointed out that two organisations acting independently, even if usually harmoniously, were less effective than a single organisation. Until a few years ago it appeared as if no form of coördination were possible except the absorption of one association by the other, a proposal which, if made, would have roused bitter opposition. A few years ago, however, to avert analogous cases to that of Ireland in Australasia, in South Africa, and in Canada, the British Medical Association altered its constitution so as to permit of autonomy in the Dominions concerned while retaining a close association with the British Medical Association. It is believed that a somewhat similar arrangement might be feasible in regard to the Irish Free State, and it is understood that conversations have been begun between representatives of the two associations, but it is still too soon to form an opinion as to their outcome.

Last week in Dublin a conference was held between delegates from the poor-law medical officers in several countries to discuss the question of medical organisation. A suggestion had been made that the dispensary medical officers should form an independent association, and the conference was originally planned to forward such a project. Before the conference was summoned, however, it was clear that opinion in the service was against an independent association. The conference was well attended, and it discussed several matters of importance to the poor-law medical service. It unanimously passed a resolution strongly in favour of the union of the British Medical Association and the Irish Medical Association. A resolution was also passed requesting the General Council of Medical Associations to appoint a committee consisting of six poor-law medical officers to study the position of the poor-law service and formulate a programme of reforms.

UNITED STATES OF AMERICA

(FROM AN OCCASIONAL CORRESPONDENT)

STERILISATION OF THE UNFIT

In its annual report for the year ending Feb. 13th, 1934, the Human Betterment Foundation of Pasadena, California, reviews the progress of sterilisation in the State of California since its first study of the subject in 1926. The State Eugenic Sterilization Law was passed 25 years ago. Up till the end of 1933 no less than 9782 persons have been sterilised, of whom 578 were operated upon in the last calendar year. These figures do not include sterilisation by private physicians of individuals at their own request, the number of these being unknown. Experience has shown that sterilisation is regarded as a protection and not as punishment, that it carries no stigma and does not affect the sex life in any way except to prevent reproduction. Dealing with the objection sometimes raised that the effect of a vasectomy, in sterilisation of the male, is permanent and may be regretted in cases of mistaken diagnosis or if the patient should change his mind, it is reported that a careful survey has shown that with proper technique operative restoration of fertility is not only possible but has been accomplished. Medical officers, probation and parole officers, and social workers all appear to be well satisfied with the operation of the law. It is stated that the policy of sterilising the unfit has been followed by a marked decrease in the number of sex offences. This is no doubt due to the possibility afforded to many to live a normal sex life to whom marriage would necessarily have been forbidden if they had not been sterilised.

AN INSTITUTE OF HUMAN RELATIONS

Mr. Paul Popenoe, who is secretary of the Foundation, also devotes a large share of his time to the direction of the Institute of Human Relations which is housed in three rooms of an office building in down-town Los Angeles (331–3, Consolidated Building). The institute provides advice to all-comers on every conceivable aspect of marriage, and in four years has been consulted by 10,000 applicants. Some of these come of their own initiative, or as a result of reading one of the institute's educational posters; a few are referred by doctors or clergy, while many are sent by the nine social agencies of the city including the Children's Protective Association, the Children's Home Society, and the Court of Domestic Relations. Analysis of the requirements of the first 10,000 clients has given the following table:—

Family maladjustment	1177	Education ..	.. 3517
Premarital consultations	1048	Child welfare	.. 753
Heredity ..	.. 184	Legal ..	.. 51
Sex problems	.. 2914	Miscellaneous	.. 356

The institute has a large volunteer corps of consultants in medicine, psychology, domestic science, Government Board. provided for the Bill of all medical of him, and no one except the Minister as his principal gr not like putting any position. He did salaries were too h speakers that the rendered, and were public. Although a rejected in the Dáil ment by 22 votes to made by the Senate The Bill as amende Dáil which can agre Its action will depen the Minister may appeared to be over- clause of the Bill, and to the Senate's amen of medical officers uni

THE IRISH M

The annual meeting tion will this year aga in the last week of be held alternately i It is intended this ye annual meeting by in- well as a business sec made to hold two sci of interest to general physicians and surgeon an old custom—unobs of holding a dinner o meeting. No credit is … reluctance to … road. In fact, … progress on the … of the point … in his own … necessary … lacks it. …

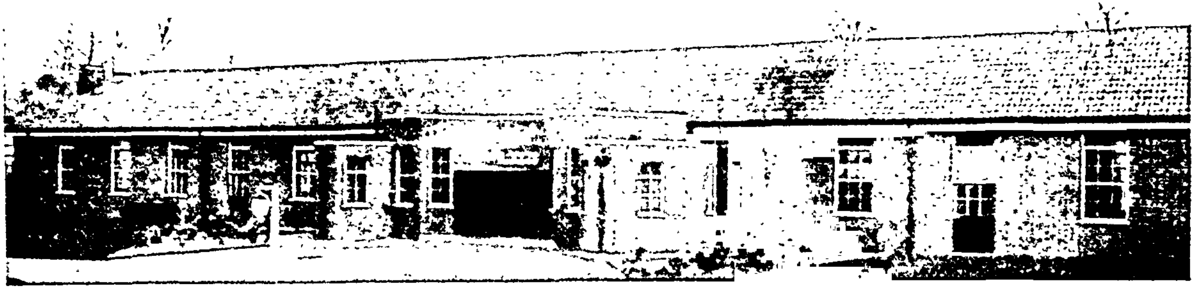

FIG. 1.—An "acute" ward block.

the premier award in the open architectural competition of 1931, in which 161 sets of plans were submitted. The administrative building is situated centrally, and the six ward blocks are placed symmetrically in terrace formation on the upper half of the sit. The ward blocks are of the one-storey type, save that in each of the two convalescent blocks a day room is formed over the centre at first-floor level. The buildings are completed in a good quality brick of pleasing shade. The grounds are suitably laid out and include two nurses' tennis-courts.

ADMINISTRATIVE BUILDING

The administrative block proper, the staff homes, and the kitchen department are grouped into one building. The building may thus be considered in three portions.

The front one-storey portion comprises the administrative section and contains: main entrance hall, doctor's office, matron's office, waiting rooms, suite for an assistant resident medical officer, matron's suite, small service pantry for these two suites, deputy matron's quarters, laboratory, dispensary and drug store, sanitary arrangements for visitors and staff.

The middle three-storey portion comprises the nurses' home and the domestic staff home. The nurses' home includes a spacious recreation room, dining hall and pantry, lecture room (with fitted blackboard and equipped with desks), 36 bedrooms, and the necessary sanitary arrangements. The domestic staff home comprises a large recreation room, dining hall with pantry, cook's quarters, 24 bedrooms (on second floor), and the necessary sanitary annexes. All sisters' and nurses' bedrooms are fitted with lavatory basins with hot and cold water.

The back portion of the administrative building consists of the kitchen and stores department. The latter comprises: kitchen, sculleries, larders, refrigeration chamber, service pantry, various stores, and mending room. The kitchen is fitted with electric ovens, and there

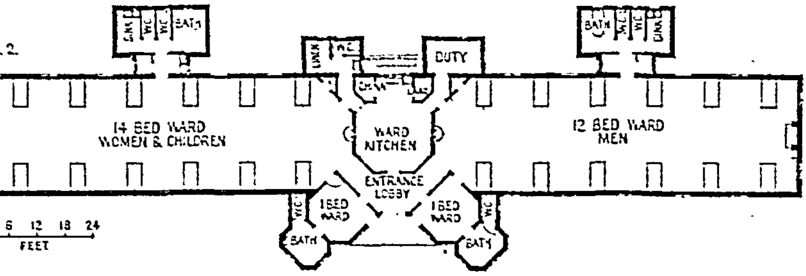

FIG. 4.

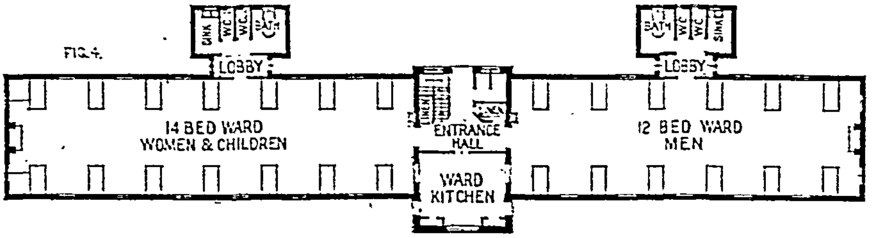

FIG. 5.

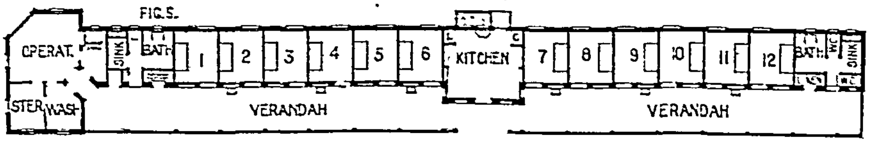

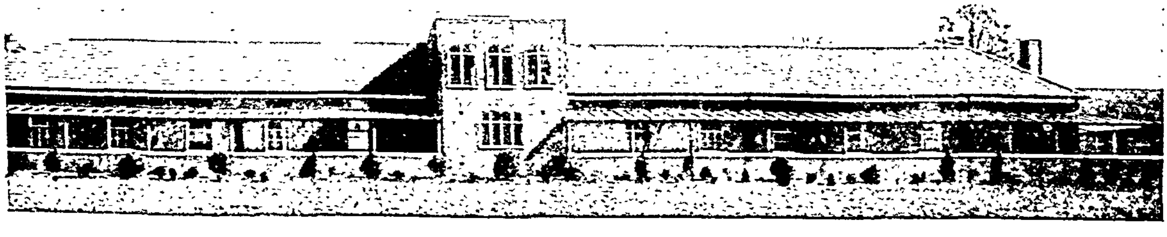

FIG. 3.—One of the "convalescent" ward blocks.

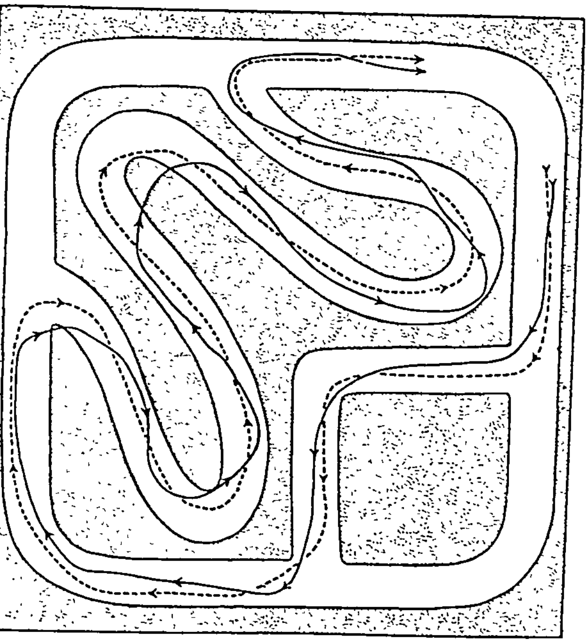
of moving towards the stationary one along a track graduated in linear measure. A button held in the hand has to be pressed to stop the approximation of one post to another, when the distance between them is deemed equivalent to the width of the screen. Several tests are made at each width of screen and the average is taken.

Judgment of speeds.—Two red objects on tracks are set at different speeds so that one overtakes or passes the other at a point hidden from the observer's view by a wooden screen suitably graduated in numbers. His task is to estimate behind what number the passing or meeting will take place. He is allowed 12 estimates in each case.

PERFORMANCE TESTS

The driving test proper, which consists of the manipulation of the controls and steering wheel of a stationary car, while a projector moving over a



IG. 2.—The dotted line represents a typical route over the track made by a good driver; the black line is the route of a bad driver. Even the good driver has cut one of the corners.

odel landscape throws a moving picture on the reen, giving an illusion of actual driving.

The car is fitted with unusual controls, so that all those sted would be equally unfamiliar with their manipula- on. There is no clutch or gear lever; the left foot is ed for foot brake and the right for the accelerator. The ack projected on the screen can be varied by the observer will, from a fairly straightforward run to the set of uous curves depicted on Fig. 2, and these can taken in either direction. The road to be travelled s a patch of grass on either side so that one who cuts e corners too sharply is liable to find himself off the road, thout "crashing" into the trees or hedges. The eering wheel has an unusually narrow lock—i.e., a very all movement produces a considerable deflection in ection.

Watched from behind the screen, the miniature track ojected is seen to be made of "grass" of green celluloid, d trees and bushes constructed cleverly of wisps of ing and horsehair. The driver is allowed ample time say 10 minutes—to accustom himself to the strange ntrols before the record of his progress is started. This sists of a tracing of his course in the form of a dotted e which records his pace as well as his direction, since pen produces ten dots every second. Variations in rate of progress therefore show in the relative distance the dots apart—for example, on the straight or round ners on the moving track.

The *confidence, road behaviour,* and *manipulative* power of a driver are estimated from a study of his record on the track.

No credit is given for excessive caution—i.e., reluctance to drive at reasonable speed on a straight road. In fact, the difference between the rate of progress on the straight and when cornering is one of the points noted, the driver who has confidence in his own abilities to slow down in good time when necessary being assessed higher than one who evidently lacks it. Much importance is attached to proper cornering, though even really good drivers are usually found to have cut one or two of the many difficult corners on the track. For the benefit of those who may feel inclined to submit themselves to these tests it may be added that only straightforward driving is required of candidates. No other vehicles are on the road, and no unexpected emergencies, other than corners, need be anticipated. The sudden appearance on the track of a cyclist or car was at one time part of the test, but it has been discontinued since the personal element on the part of the observer who timed its incidence could not be excluded. Since the test is first and foremost a comparative one, any variation of this sort would tend to invalidate the results.

THE TESTS AS A WHOLE

A very large number of statistics would be required to prove definitely that the record of accidents incurred by drivers successful in these tests is significantly less than that of those whose response was relatively unsatisfactory. But such evidence as has been accumulated at the Institute points to this conclusion. The psycho-physical tests appear to us to be peculiarly well fitted to their purpose, especially the first three tests described above. Our representative, a doctor with driving experience extending over 25 years, was unable to complete the road tests, being one of the very few—less than 2 per cent.—who find that nausea is induced by the attempt to follow a track under the conditions offered. The factor responsible for this rare disability has not yet been ascertained. Without going so far as to suggest that all tests of behaviour on the actual highway, though their value is admittedly limited, should be superseded by those described above, we warmly endorse the plea made by Sir Ernest Graham-Little in the *Times* of April 23rd for the enlistment of the help of the industrial psychologist in planning tests suitable for mass application.

THE NEW ISOLATION HOSPITAL AT COVENTRY

THE opening on Monday last at Coventry of a new hospital of 148 beds for the isolation of infectious disease is an event of interest to those engaged in hospital administration. We are indebted to the medical officer of health, Dr. Arthur Massey, for the following account.

The site on which the hospital stands is 1¾ miles from the centre of the city; it comprises 16 acres, while 10 further acres of adjoining land have been reserved for future extension. The situation is open and the gentle slope gives a southerly exposure. The subsoil is of marl, clay, and sand. The buildings have been erected to the plans which won for their author, Mr. Stanley Atkinson (of Messrs. Wimperis, Simpson, and Guthrie, architects, London),

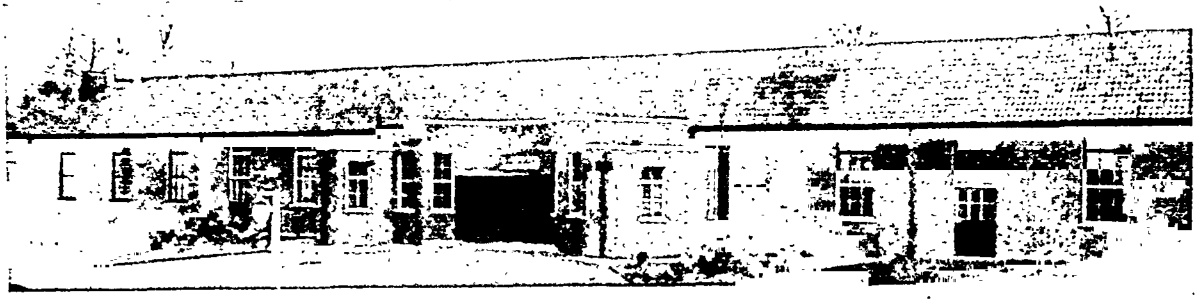


FIG. 1.—An "acute" ward block.

the premier award in the open architectural competition of 1931, in which 161 sets of plans were submitted. The administrative building is situated centrally, and the six ward blocks are placed symmetrically in terrace formation on the upper half of the sit. The ward blocks are of the one-storey type, save that in each of the two convalescent blocks a day room is formed over the centre at first-floor level. ADMINISTRATIVE BUILDING

The administrative block proper, the staff homes, and the kitchen department are grouped into one building. The building may thus be considered in three portions.

FIG. 4.

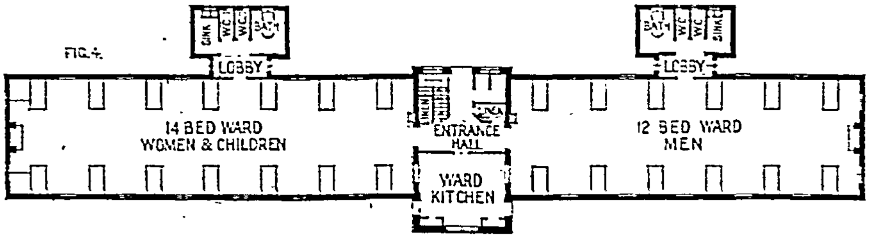

FIG. 5.

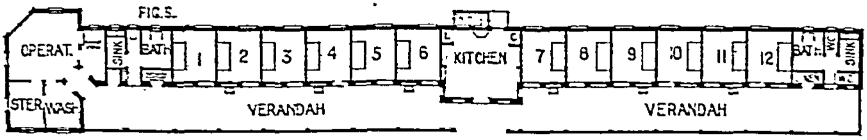

The front one-storey portion comprises the administrative section and contains: main entrance hall, doctor's office, matron's office, waiting rooms, suite for an assistant resident medical officer, matron's suite, small service pantry for these two suites, deputy matron's quarters, laboratory, dispensary and drug store, sanitary arrangements for visitors and staff.

The middle three-storey portion comprises the nurses' home and the domestic staff home. The nurses' home includes a spacious recreation room, dining hall and pantry, lecture room (with fitted blackboard and equipped with desks), 36 bedrooms, and the necessary sanitary arrangements. The domestic staff home comprises a large recreation room, dining hall with pantry, cook's quarters, 24 bedrooms (on second floor), and the necessary sanitary annexes. All sisters' and nurses' bedrooms are fitted with lavatory basins with hot and cold water.

The back portion of the administrative building consists of the kitchen and stores department. The latter comprises: kitchen, sculleries, larders, refrigeration chamber, service pantry, various stores, and mending room. The kitchen is fitted with electric ovens, and there

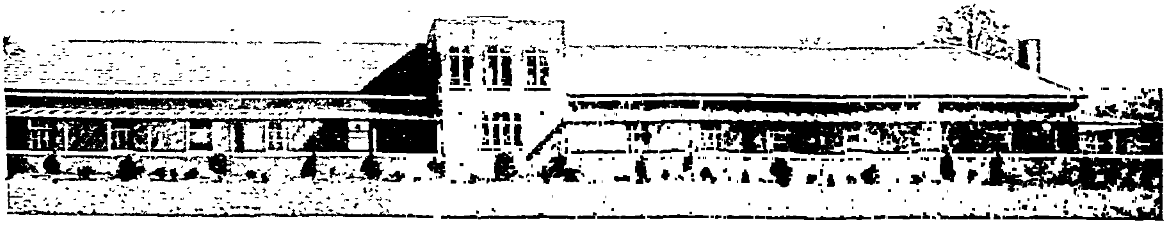

FIG. 3.—One of the "convalescent" ward blocks.

are electrically driven machines for various culinary processes. The prepared meals are delivered from the central kitchen to the wards, &c., in trolleys fitted with electrically heated containers.

The administrative building is sufficiently large to meet possible future extension of the hospital proper.

The hospital proper has 148 beds, distributed as follows: 28 beds in each of the three "acute" ward blocks, 26 beds in each of the two convalescent ward blocks, and 12 beds in the cubicle ward block.

THE "ACUTE" WARD BLOCKS

In each of the "acute" blocks there are two main wards containing 14 beds and 12 beds respectively and two single-bed wards. It will be observed (Fig. 1) that the two extensions containing the single-bed wards are located in the front of the block—one at each side of the central entrance—giving relief to the front elevation.

Each of the single-bed wards (Fig. 2) is self-contained—i.e., with its own bathroom, containing bath, lavatory, and w.c. Besides having access from the main ward, each single-bed ward has access from the lobby in the general entrance to the block and also direct access from outside. This enables the single-bed ward to be put to various uses; it might be used for a paying patient; it can be used for an especially severe case of the same disease as is under treatment in the main ward adjoining; or again it can be used for a case of a different disease from that under treatment in the main ward adjoining.

The two main wards are of such dimensions that there is a floor space of 144 sq. ft. per bed and a wall space of 12 ft. linear per bed. The wards are 12 ft. high. The two sanitary annexes are located at the rear of the block; each is placed midway along the posterior wall of the ward it serves, and contains bathroom, two w.c.'s, and a sluice room with bedpan steriliser, &c.

The nurses' ward-kitchen in each block is placed centrally, and leading from it at the rear are a sisters' duty room, linen room, and a room containing lavatory and w.c. for staff.

The arrangement whereby simultaneous observation of the two main wards is obtained from the central ward-kitchen is interesting. Observation of the single-bed ward on each side is enabled by two opposite windows which give a view across the intervening part of the lobby.

THE CONVALESCENT WARD BLOCKS

In each of the two convalescent ward blocks (Fig. 3) there are two main wards containing respectively 14 beds and 12 beds. There are no single-bed wards in these blocks. The entrance to the block is placed at the rear, while the central ward-kitchen faces to the front. A day room, approached by stairs from the entrance hall, is formed over the central part of the block at first-floor level.

Along the front of each ward a spacious verandah (not shown on the plan—Fig. 4) is provided; each verandah has access both from the ward-kitchen and from the ward it serves. The verandahs are comparatively low and very "deep" from front to back, and there is a "footing" wall in front; these are simple but indispensable points in a verandah which is to give adequate protection from the weather.

THE CUBICLE BLOCK

The cubicle block (Fig. 5) contains 12 beds, each of which is placed in a separate cubicle 12 ft. by 10 ft. The block also includes a nurses' ward-kitchen, stores, and two sanitary annexes each containing bathroom, one w.c., and a suitably equipped sluice room.

The sanitary annexes are placed one at each end of the block. Along the front of the whole block is an adequate verandah. On the latter and affixed at intervals to the outer aspect of the front wall of the block are six lavatory basins—three on each side of the central entrance to the block. These are, of course, to enable the physician, passing along the verandah from cubicle to cubicle—i.e., from one type of infection to another—to perform the necessary hand ablutions en route. In connexion with these externally placed basins, the water-supply pipes and the waste-pipes are so placed as to afford protection from the possible effects of frost—an elementary but noteworthy point.

From the central ward-kitchen, through observation of the 12 cubicles—six on each side—is enabled by means of glass panels in the dividing walls. In this connexion the perspective view of the cubicles is notably improved by the scheme of their internal decoration; six of the cubicles are finished in one colour and six in another, the cubicles of one colour alternating with those of the other. This simple expedient clearly "picks out" the individual cubicles as they are seen from the ward-kitchen.

The small operating theatre is attached to one end of the cubicle block. It contains a theatre, sterilising room, wash-up room, and blanket store.

MATERIALS AND TECHNICAL SERVICES

The floors of all wards are of "jarrah" wood boarding (Australian). The floors of lobbies, ward-kitchens, sanitary annexes, operating theatre unit, and the like are of terrazzo. The doors in the wards are of Canadian pine and the window frames of metal. The walls are rendered in plaster and finished with best washable paint. All corners and joints between floors and walls are well rounded. The internal decorations of the wards are carried out alternately in shades of sunshine yellow and pale green, while the vestibule of each ward block is finished in aluminium. In the scheme of electrical lighting, artistic lamp fittings are a feature, and in all wards there is a shaded wall light to each bed. A system of panel heating gives an adequate and even distribution of heat in the wards.

The technical services are grouped together in the power block. The laundry contains three separate receiving rooms for staff linen, patients' linen, and foul linen respectively. A full-sized steam disinfector is installed. The boiler house contains the heating and hot-water supply plant, and a small engineer's workshop. Adjacent to the boiler house is a water-softening plant. Garage accommodation is provided for three motor ambulances and for three other vehicles. Complete inter-communication between the buildings is secured by a system of internal telephones. A fire alarm system gives direct contact with the city fire station. The mortuary, attached to the power block, has accommodation for six bodies, and includes a post-mortem room and a viewing room.

COST

The cost of the hospital (excluding site) will be in the region of £113,000. The land comprising the site has been in the possession of the corporation for many years; the portion now occupied by the hospital is valued at £8000. This works out at about £820 per bed. The new hospital supersedes the old city hospital of 102 beds, which has been sold by the corporation to the Coventry and Warwickshire Hospital, to which it is adjacent.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN. The report for 1933 states that, notwithstanding the additional accommodation, there is still a waiting-list. There is an even more pressing need for a ward for children under three years of age, and the provision of pay-beds will have to be considered seriously "when times are more propitious." The out-patient department is congested, but the cost of rebuilding the hospital to incorporate the in- and out-patients' departments would be £60,000. In-patients last year contributed £968 and out-patients £1779; the excess of total income over total expenditure was £2171.

are electrically driven machines for various culinary processes. The prepared meals are delivered from the central kitchen to the wards, &c., in trolleys fitted with electrically heated containers.

The administrative building is sufficiently large to meet possible future extension of the hospital proper.

The hospital proper has 148 beds, distributed as follows: 28 beds in each of the three "acute" ward blocks, 26 beds in each of the two convalescent ward blocks, and 12 beds in the cubicle ward block.

In-patients last year contributed £968 and out-patients £4779; the excess of total income over total expenditure was £2171.

PANEL AND CONTRACT PRACTICE

Vexed Points in Certification

CERTIFICATION continues to receive attention from the approved society side, as it may well do, for on its adequate performance depends stability for their funds. At a recent conference between representatives of the Insurance Acts Committee and of approved societies a consensus of opinion was reached in relation to certificates given to pregnant women.

(*a*) That a medical certificate shall be held to be inadequate if it certifies the incapacity for work of the insured person on the ground of pregnancy alone.

(*b*) That a medical certificate shall be held to be inadequate if it certifies the incapacity for work of the insured person on the ground of pregnancy even with an indication of the period of pregnancy.

(*c*) That a medical certificate shall be held to be adequate if it certifies the incapacity for work of the insured person on the grounds of pregnancy and some disabling associated condition.

(*d*) That a medical certificate shall be held to be adequate if it certifies the incapacity for work of the insured person on the grounds of pregnancy, plus an indication of the period of pregnancy, and plus the character of the employment of the insured person.

DIAGNOSIS

The expression on the certificate of the nature of the incapacity is also under review. Societies complain that medical practitioners do not often give them sufficient information as to what is the matter with a patient; they receive certificates week after week for the same symptom, such as diarrhœa. This may be the correct cause of an insured person being unable to work, but it does not enable the society to form an opinion whether the case is likely to be a long or short claim upon its funds, nor can its sickness visitor decide whether home conditions are such that the member is taking proper care of himself or that the doctor's instructions are being carried out. Practitioners may be roughly grouped into two classes; those who frequently change the name of the incapacity entered up on the certificate, according to the condition of the patient, and those who do not.

For example, a doctor in the former group might issue a series of certificates week by week to the same patient, such as pyrexia, bronchial catarrh, influenza, pleurisy, pneumonia, emphysema, *discharging sinus, debility following*, &c. The risk he used to run was from the society's official concluding "this doctor obviously does not know what is the matter with this case: the diagnosis keeps changing—better send it to the regional medical officer." On the other hand the doctor who starts with the certifying a case of influenza as influenza, and repeats this as the cause of incapacity, runs the risk of the official saying "influenza does not as a rule last more than three weeks, something must be wrong here—better send it to the regional medical officer."

Probably in these days, with more experienced officials inspecting and scrutinising certificate forms, it is better to change the diagnosis of the cause of incapacity according to the stage of the illness rather than to adopt the second method of always using the same term.

PROGNOSIS

Society representatives report that extraordinarily few certificates ever have filled up on them the space provided for remarks or the date on which the patient should come to see the doctor again. It is thought that the use of this latter provision might considerably reduce the amount of money paid out in sickness benefit. Patients are apt to attend weekly and unless told on Monday to come again on (say) Wednesday, when they might probably be given a final certificate, they do not turn up again until the following Monday when, if they then get a final certificate, they will be be receiving about five days pay more than if they had been signed off as soon as thought to be fit for work. It has been suggested, though never seriously considered by either side, that possibly some wording might be added to the present certificate form under which the doctor might be asked in the first intermediate certificate to say approximately how long the illness would be likely to last, in such terms as: "You should in all probability be fit to resume work in —— days time." This would have the effect of putting the certifying doctor on his mettle to estimate as accurately as possible the severity of the trouble. It would inform the society as to how serious the doctor thought the incapacity was; the patient would realise quite early in trivial cases that the doctor did not think there was much the matter and, with some patients very loyal to their doctors, they would often do their utmost to be fit to time so as not to let their medical man down with the approved society.

The Post-office form of certificate for the employee contains a somewhat similar form of words. There it works smoothly and is found helpful to officials administering sick funds. No one could of course be accurate in such estimation of duration of incapacity and mistakes would be certain to occur in every doctor's prognosis, but results reviewed in aggregate would indicate the careless certifier, the percentage of his errors being much above the average.

FITNESS FOR HOUSEWORK

Recently Mr. Parkinson asked the Minister of Health in the House of Commons if he has authorised the decision that when an insured person who is in receipt of National Health Insurance benefits is certified by a medical officer as being able to do housework, though unable to follow her usual occupation, her benefits shall cease even though she intends to resume her own occupation as soon as her health will permit. The reply of the Minister is illuminating. He said there was no general decision that an insured woman who, though unable to follow her usual occupation is able to do housework, is to be treated as not entitled to sickness or disablement benefit. An approved society would not ordinarily regard such a woman as disentitled to benefit pending her early return to her normal employment. But in the case of a woman who is the domestic head of a household, and for whom accordingly the performance of household duties is in the nature of an alternative to her industrial employment, fitness for the former as well as for the latter form of work would probably be taken into consideration. Every case was to be considered on its merits and any woman who is dissatisfied with the decision of the society is entitled to appeal in accordance with the rules.

This question of housework is frequently raised by approved societies when sending cases to the regional medical officer. Insurance practitioners are not asked to certify on this question, they certify whether the insured person is fit to return to her normal employment. The position is not without difficulty for both parties, and it frequently arises on so-called Class K cases where a woman with employment ceases work on marriage and never intends to return to that employment. Some incapacity arises for which she claims a financial benefit under the

Act; what standard of employment is to be considered as applicable in such a case? Certainly not the last occupation, because that is finished for good; probably the housework standard is the fairest—the ability to do unaided the ordinary household duties of a working-class home. It will be noted in the Minister's reply that he suggests to any one dissatisfied that she should appeal. The result of such an appeal would be interesting. The decision on payment of financial benefit rests with the society, which would have to justify its decision before the appeal tribunal.

Temporary Residents

Dr. W. L. HARDMAN (Grange-over-Sands) writes: "Having read the note in THE LANCET of April 14th (p. 813) on remuneration for the temporary residents in a convalescent home, I thought it might interest you to know the point of view of a doctor who is distinctly dissatisfied with the rate of pay for these patients. This afternoon I have seen 25 patients, four of whom I considered needed treatment, and whose cards I took. For this work (2 hours) I receive 2s. 2d. or 6½d. each. I have to see all the new arrivals in case they are ill while resident there, but cannot take their cards, as evidence of treatment has to be given before pay is made. The other night at 10.30 P.M. I had to see a man and take him to hospital (16 miles away), arriving back at 2 A.M.; there is no appearance of receiving any extra pay for this man—just his 6½d. Quite often one has to see a man whose card one has not had in an emergency. As all these men (or women) have to be seen, I think the rate of pay should be higher."

OBITUARY

FREDERIC NEWTON GISBORNE STARR, C.B.E., M.D. Toronto, F.A.C.S.

THE death is announced by telegram as having occurred on April 21st of Dr. Frederic Newton Gisborne Starr, emeritus professor of surgery in the University of Toronto. His reputation as a surgeon was a distinguished one in Canada, in the United States, and in this country.

Prof. Starr was born in 1867 at Thorold, Ontario, the son of the Rev. Joseph Starr, and received his education at the High School, Toronto, and at the University in the city. He graduated as M.B., C.M. in 1889 and specialised in surgery from the beginning of his career, the greatest part of which was spent in Toronto. After holding numerous resident posts he was appointed surgeon to the General Hospital, Toronto, and in succession to the Hospital for Sick Children and to the Women's Hospital, and alike as teacher and practical exponent was recognised as a leader in his science. He held a particularly prominent place in medical organisation, his management of affairs being notable. He was for an extended period general secretary of the Canadian Medical Association, and was later a member of the executive of that body, becoming finally president in 1927. He served on the Council of the College of Physicians and Surgeons of Ontario from 1907 till 1911, and was president of that corporation in 1931–32. In the latter year he was elected vice-president of the American Surgical Association, while he was also vice-president of the American College of Surgeons, and during a meeting in Canada of the British Medical Association was chosen as a vice-president of that body. During the war he served with the R.A.M.C. in France with distinction, being mentioned in despatches and receiving the C.B.E. at the termination of hostilities. The figure of no Canadian was more familiar to British surgeons than his.

Prof. Starr married in 1904 Ann Callander, daughter of Mr. G. F. MacKay, of New Glasgow, Nova Scotia, but there was no child of the marriage. He was as widely known in Toronto society as he was in the academic world, being a familiar figure in the sporting and social clubs and associations of the city. His death is deeply regretted.

RICHARD LLEWELLYN JONES LLEWELLYN, M.B. Lond.

THE death is announced as occurring on Thursday, April 19th, of Dr. Richard Llewellyn Jones Llewellyn, who was well known in association with the treatment of rheumatism and allied conditions. He died in his sleep.

Dr. Jones Llewellyn was the son of an officer in the R.A.M.C., Major Morris Jones, of Aberystwyth, and was educated at Epsom College, University College, London, and the University of Wales. He qualified in 1894 as L.S.A., and in the following year graduated as M.B. Lond., taking also the English double qualifications. After being surgical assistant in the out-patient department at University College Hospital, he was for a time a resident medical officer in the Durham County Asylum, after which he started in medical practice in Aberystwyth. Later, and being by this time particularly interested in the numerous problems associated with arthritis and allied rheumatoid conditions, he commenced practice as a specialist in those disorders at Bath, and was appointed physician to the Royal Mineral Water Hospital at Bath. He now wrote voluminously on the subject, among his earlier contributions to medical literature being a book written in association with his brother, Dr. A. Bassett Jones, of Llandrindod, on fibrosis and neuritis, muscular rheumatism, and sciatica, a work which met with considerable approval and went into a second edition. Other contributions from his pen on the same subjects appeared in Latham's and English's System of Treatment, while he also wrote a treatise on gout, which was translated into French. Llewellyn possessed a picturesque and forcible style and his messages were always clearly delivered.

During the war Llewellyn, as a member of the Central Appeal Tribunal of the Ministry of Pensions, continued to impress upon the profession and the public the gravity of rheumatism as a menace to national efficiency, developing his arguments in a book on the principles which should regulate the evaluation of pensions, and writing and speaking much on his thesis and on malingering. The book was written in collaboration with his brother and the late Mr. W. M. Beaumont, the ophthalmologist. Llewellyn was a member of the Conference on Chronic Arthritis and Allied Rheumatoid Conditions convened by the Medical Research Council, and took an active share in starting an inquiry into the systematic prevention and relief of diseases in children. He held office in the section of physical medicine of the Royal Society of Medicine and was also president of the balneological and clinical section. Recently he had become interested in the possible association between rheumatic symptoms and certain dermatological conditions, and on the agenda for the next meeting of the Medical Society of London is the announcement of a paper by him (which will be read by Dr. D. F. Fraser Harris) on the skin in relation to rheumatism in childhood and after puberty.

Dr. Llewellyn, who took the additional surname of Llewellyn on that occasion, married in 1911 the Hon. Avis M. Blennerhasset, only child of the fourth Lord Headley and widow of Mr. D. H. Crosse.

ANDREW McFARLANE, M.D., M.R.C.P., D.P.H.

THE death occurred recently of Dr. Andrew McFarlane, who had recently been appointed medical officer of the Scottish Board of Health, and who had previously made his mark by his organising work as deputy medical officer, Darlington.

Andrew McFarlane, the son of James McFarlane, J.P., was born at Leadhills in 1898, and educated at Biggar Grammar School and the University of Edinburgh. He graduated as M.B., Ch.B. with honours in 1922, proceeded to the M.D. degree in the following year, took the M.R.C.P. Edin. in 1926, and the D.P.H. Edin. in 1927. His early professional life was a full one, for after filling the appointment of house physician to the Edinburgh Royal Infirmary, he was clinical tutor at the infirmary for a year. Next followed one year as R.M.O. at the Ministry of Pensions hospital, while later he was medical officer to the Tuberculosis Hospital in Edinburgh, and served as clinical assistant in the venereal department of the Royal Infirmary and at the Edinburgh Tuberculosis Dispensary. He was now for a brief time assistant medical officer to the Surrey county council, but in 1929 became deputy medical officer at Darlington, holding the post of assistant medical officer for education purposes and medical officer for venereal diseases. His work received the highest commendation from his superior officer, and when he decided to apply for the vacant post of medical officer to the Scottish Board of Health he had in his support a fine record of academic and practical success. In this last appointment he unfortunately never had any opportunity of displaying his talents, for illness prevented him from taking up the post, and after more than one unsuccessful operation he died at the early age of 36.

DAVID LECHMERE ANDERSON,

L.R.C.P. & S. Edin., D.P.H. Edin. & Glasg.

WE regret to announce the death of Dr. David Lechmere Anderson, the well-known medical officer of health for Doncaster, which occurred on Wednesday, April 18th, at his home in that town. Although his death was not expected he had been in bad health for several weeks.

Dr. Anderson received his medical education in Edinburgh and took the double diploma of the Edinburgh Colleges in 1883, being then only just of age. He was a promising student and a medallist of the University of Edinburgh. He was for a period in general practice but, deciding to devote his time to State medicine, became M.O.H. for the borough of Peterhead and Ellon. In 1902 he was appointed M.O.H. for Doncaster, where in virtue of his office he was also medical inspector of schools and medical superintendent of the infectious diseases hospital, while he was also certifying factory surgeon. It was in relation to his interest in industrial disease that his best piece of work was done, when he made an inquiry into the possibility of reducing the amount of miners' nystagmus in the coal-fields. The inquiry was published in the *British Medical Journal* in 1920, and Anderson went closely into the relation of age as a factor in the production of miners' nystagmus, inquired into causation and the influence of heredity, and closed with a practical suggestion for the standard of admission to pit life judged by the normality of vision. He suggested that no youth should start work in a mine with imperfections of vision, while he attributed the disease, as others did, mainly to the bad lighting of the galleries in the coal-fields coupled with the abnormal postures which it was necessary for the miners to adopt. Dr. Anderson showed versatility, also, by contributing not only with frequency to the press upon health subjects but by writing serial fiction under the name of David Lechmere. He was a recent widower, but leaves a son in the medical profession.

NORMAN LAVERS, M.D. Brux., L.R.C.P. Lond., M.R.C.S. Eng.

BY the recent death of Dr. Norman Lavers, medical superintendent of Bailbrook House, Bath, the profession has lost a practitioner well known for his practical work as a medico-psychologist. A Tasmanian by birth, he received his medical training at Guy's Hospital medical school and qualified with the English double diplomas in 1896, proceeding later to the M.D. Brux. His professional life was spent in the institutional treatment of nervous disorders. His first post was as resident at Camberwell House, London, and after service there as senior medical officer he was appointed medical superintendent of the Canterbury City and Borough Asylum. He showed himself particularly interested in the neurological problems presented by his charges, and wrote shrewdly on the clinical aspects of functional disorder. He was then appointed superintendent of Bailbrook, Bath, and during the war held a temporary commission in the R.A.M.C., becoming consultant in nervous disorders to the Bath War Hospital. He had retired from professional work at the time of his death, but he held the post of medical superintendent of Bailbrook for over 20 years and earned a reputation for sound and scientific work.

BIRMINGHAM'S SPECIALIST HOSPITALS.—The annual reports are now published of the Birmingham and Midland Eye Hospital, the Birmingham and Midland Ear and Throat Hospital, and the Birmingham and Midland Skin Hospital. Last year the Eye Hospital treated 44,350 new out-patients, of whom over 26,000 were casualty cases. There were 1611 in-patients in the public wards and 117 private patients. The public patients showed a reduction of 234, which is attributed mainly to fewer cases of infantile ophthalmia. The follow-up work in connexion with cases of ophthalmia neonatorum continues to be attended with marked success. It was stated at the annual meeting that the time cannot be far distant when a complete rebuilding scheme will have to be considered, and that the nurses' home must shortly be rebuilt. The Ear and Throat Hospital is also in need of larger accommodation. The Skin Hospital is to have a new in-patient department at 35, George-road, Edgbaston, formerly a nursing-home. The existing house is to be utilised as a nurses' home, and the wards and their accessories will be housed in a new three-floor block. There will be 14 beds and a private ward for men, a similar number for women, with three private wards, a 16-bed ward, and three private wards for children. The present in-patient accommodation will thus be increased by 29 beds; the existing premises in John Bright-street will continue to be used as the out-patient department.

CORRESPONDENCE

THE BLOOD-BRAIN BARRIER IN INFECTIOUS DISEASES

To the Editor of THE LANCET

SIR,—I have been much interested in Prof. Friedemann's paper, especially in regard to the mode of action of diphtheria toxin. Like Dr. Goodall, I had not expected to find the ultimate action of diphtheria toxin ascribed to an effect on the brain or higher centres, and I am in complete agreement with him that all clinical observation points to a peripheral action. I cannot however go all the way with him in thinking that circulatory changes are chiefly peripheral, if by that, as I rather gather from his preceding remarks, he means chiefly vascular. The profound disturbances in heart rhythm, and the gross degenerative changes noted in both contractile and conductile tissues on histological examination, in my opinion point to a direct primary action of the toxin on the heart itself. While there can be no doubt that the changes in the peripheral circulation are also important, I must agree with Warthin that the essential lesion in the majority of cases of heart failure in diphtheria is in the myocardium itself. I am, Sir, yours faithfully,

ALEX. JOE.

North Western Hospital, Hampstead, N.W., April 23rd.

SAFE MILK

To the Editor of THE LANCET

SIR,—I congratulate Major Lings on the outspokenness of his letter in your last issue in regard to loose milk delivery. In view of the Government's proposal to grant funds for milk publicity and for the encouragement of milk production, I think it is very important that the equally vital distributive link in the chain of supply should not be overlooked. It is obviously sound to synchronise steps for the improvement of supplies on the farm, in order to restore public confidence in milk, with propaganda for its increased consumption; but it is equally advisable to ensure that any raising of production standards is not neutralised by a reverse tendency in the distributive sphere.

At the moment one finds in almost every town retailers of raw milk and pasteurised bottled milk working side by side on exactly the same margin, despite the fact that an extra expenditure of at least 2*d.* to 2½*d.* a gallon is incurred by the second class of distributor in respect of processing and bottling undertaken with a view to rendering supplies as safe and reliable as possible. This is obviously quite inequitable and, in view of the Board's demand for still further reductions in the margin, can only mean that unless some discrimination is made there will be a tendency for the standard of distribution to retrogress rather than progress.

Now that the industry is highly organised, there appears to be no insurmountable difficulty, however, in arranging for the margin to be fixed on the basis of the distributing costs of raw milk, while firms who supplied pasteurised bottled milk received a rebate from the Board adequate to cover the average costs of this service. The retail selling price would of course remain the same in both cases. The Board would then receive a better average return on liquid milk sales as a whole, since instead of a margin of 1*s.* on all milk, 9½*d.* only would be allowed, subject to a rebate as above, while a higher standard of distribution would be encouraged for the good of the industry as a whole.

Unless and until there is a definite inducement for the retailer to turn over from the unhygienic system of loose milk delivery, I am dubious whether funds voted for improving the milk-supplies of the country will achieve their object—increased public confidence. And, unless the latter can be achieved, expenditure on advertising will certainly not bring the results which would otherwise accrue.

I am, Sir, yours faithfully,

Shalford, Surrey, April 20th. VALDER GATES.

THE RECOGNITION OF CHIROPODY

To the Editor of THE LANCET

SIR,—In the leading article of the last issue of THE LANCET, on the recognition of chiropody, Sir Henry Brackenbury is reported as saying: "What was he to do if a patient came to him with a bunion which he did not care to treat? He considered it common sense that such sufferers should go to the chiropodist."

I feel sure that the medical profession welcomes the recognition of chiropody, which by the definition agreed upon includes the treatment of all superficial excrescences occurring on the feet, such as corns, warts, callosities, and bunions. It would, however, be a pity for a medical man to advise chiropody in the case of a patient suffering from a bunion without considering the merits of the case; for the various treatments given by chiropodists for bunions are palliative and fail to get to the root of the trouble. There are alternative lines of treatment and it may require considerable experience to decide which is the most appropriate.

We meet cases in which chiropody has failed, not because it was badly done, but because it was not the right treatment; and it will be a pity if chiropodists are to be saddled with the care of such cases, for failure will bring their methods into disrepute.

I am, Sir, yours faithfully,

Portland-place, W., April 23rd. A. T. FRIPP.

TOBACCO SMOKING AND DUODENAL ULCER

To the Editor of THE LANCET

SIR,—In reply to Dr. Askey there is, I think, no doubt that the smoking of a given amount of tobacco on an empty stomach produces a much greater "nicotine effect" than the smoking of an equal amount of tobacco after a meal. This phenomenon is common to all forms of smoking and is not peculiar to cigarette smoking. The normal mode of entry of nicotine into the system is by its distillation from the hot tobacco into the mouth, where it dissolves in the saliva, is swallowed, and finally is absorbed into the blood from the stomach or small intestine or both. When the stomach is full the nicotine-saliva is diluted by the gastric contents and possibly some of the nicotine is destroyed by the digestive juices, consequently the amount of nicotine absorbed is less.

That the swallowing of tobacco dust by the cigarette smoker materially adds to the amount of nicotine absorbed seems to me very unlikely, for if it did we should expect to find cigarette smoking producing a greater nicotine action than the smoking of an equal quantity of tobacco in a pipe, whereas the reverse is true; but this does not mean that the swallowing of tobacco dust is unimportant, for if tobacco itself is swallowed there may be toxic substances other than nicotine present in the gastric "brew." If this latter hypothesis is correct one would expect to find a high incidence of duodenal ulcer among tobacco chewers, but whether or not this is so, I do not know.

I agree that the question of smoking before meals should be investigated, though I do not see why breakfast especially should be incriminated. My own view is that for the prospective duodenal ulcer patient ordinary (non-inhaling) cigarette smoking is possibly harmful, inhalation of cigarette smoke is harmful, and inhalation on an empty stomach is very harmful.—I am, Sir, yours faithfully,

O. A. TROWELL.

Dept. of Physiology, University of Liverpool,
April 23rd.

PARAPHARYNGEAL ABSCESS

To the Editor of THE LANCET

SIR,—On p. 878 of your current number you print an abstract of an article by MM. J. Piquet and P. Coumouma on lateral pharyngeal abscess. This is, I feel sure, the condition I described four years ago in your columns (1930, i., 792) as "parapharyngeal abscess." As the authors point out this is not a peritonsillar abscess, but is situated externally to the wall of the pharynx. They state that it arises in the lymph glands about the carotid sheath; but I still maintain that although cervical gland suppuration may occur in some cases, the essential feature is "a suppuration in the bucco-pharyngeal aponeurosis behind the palato-pharyngeus muscle and posterior faucial pillar. It tends to point in the pharynx about the level of the lower pole of the tonsil, in the potential gap between the palato-pharyngeus muscle in front, the lower border of the superior constrictor above, and the stylo-hyoid ligament (with the middle constrictor) behind." And it can be readily opened in this situation—far more readily than by the external route that MM. Piquet and Coumouma advocate for adults—the internal route being kept for children. It is an important condition to recognise, owing to its immediate relations with the great vessels of the neck, which have been eroded in several recorded cases: and it can be readily distinguished clinically from peritonsillar abscess—reserving this term for suppuration between the capsule of the tonsil and the sinus tonsillaris.

I am, Sir, yours faithfully,

Clifton, Bristol, April 20th. E. WATSON-WILLIAMS.

BROMIDE OF STRONTIUM IN EPILEPSY

To the Editor of THE LANCET

SIR,—Many years ago I wrote a letter to THE LANCET (1912, i., 1644) with reference to the treatment of epilepsy with bromide of strontium. Experience since then has confirmed me in the belief that the treatment of epilepsy with this salt is far superior to that with other bromides. The dose of ʒi. for adults is well borne and does not cause depression. I have had many cures by its use. Details of all these cases are in my case book, which I should be happy to submit to any competent authority for consideration.

As I am in my 79th year, I am anxious that this form of treatment should not be lost sight of, but be carried on by others.

I am, Sir, yours faithfully,

M. R. CALLENDER,
Surgeon.

Bridgwater, April 16th.

SURVIVAL AFTER 600 GRAINS OF ASPIRIN

To the Editor of THE LANCET

SIR,—In view of the fact that the largest dose of aspirin taken without fatal result appears to be 485 grains, as recorded in Martindale's Extra Pharmacopœia, it is of interest to report a case of attempted suicide in which 600 grains of aspirin failed to have the desired result. A man aged 48 years, after a drinking bout, swallowed 120 five-grain tablets at midnight. An hour and a half later he became violently sick and continued to vomit until about 11 o'clock the following morning. When I first saw him at 7 P.M. on the same day he was comparatively comfortable and required no active treatment. His symptoms had been, at first, a very acute but transitory attack of perspiration and then the intensive vomiting, which no doubt saved his life. He was still complaining of a "rushing feeling" in his head and neck. Against advice he was up and about his work in a couple of days.—I am, Sir, yours faithfully,

Edinburgh, April 17th. S. LIPETZ.

MORTALITY AFTER PROSTATE OPERATIONS

To the Editor of THE LANCET

SIR,—Sir Francis Shipway has been good enough to point out to me that, in my two letters (THE LANCET, 1931, i., 1423, and ii., 325) reporting a series of 402 cases of prostatectomy operated on under a combination of a very small amount of spinal and general anæsthesia, I had omitted to mention whether the short or the longer operation was used. To make the report more complete I should like to say that in all these 402 cases it was the short operation, without exposing the bladder, which was used. In my experience the above-mentioned method of anæsthesia is also the best for the longer operation but a little more of the spinal anæsthetic must be used. I am, Sir, yours faithfully,

London, April 20th. H. M. PAGE.

A BUDGET REACTION.—We have received from a group of co-signatories, partly medical, a letter criticising the Budget, in that the Chancellor, "has failed to apply his first principle of using his surplus to relieve those classes who suffered most when the crisis was acute. . . The Children's Allowance still stands at 2s. a week; the Means Test is still enforced; while the cost of Statutory Benefit to the unemployed is still borne to a large extent by working class families." As a protest the writers have decided to send a part of the benefit accruing to them from the reduction in the income tax to the following two organisations: the Committee against Malnutrition, 19c, Eagle-street, London, W.C.1, and the Children's Minimum Committee, Thames House, Millbank, London, S.W.1. They hope that the example will be followed by others.

GOLDEN-SQUARE THROAT HOSPITAL.—At the annual meeting last week it was reported that although the year's income had fallen by £3465, expenses had also been reduced and the year ended with a small credit balance. It has been decided to reduce the number of private wards and to form them into a single wing. The remainder of what were previously private wards are to be devoted to contributory patients under special conditions. It is hoped that this will stimulate further use of the private wards and help the revenue of the hospital.

PUBLIC HEALTH

List of Special Schools

THE list of special schools issued by the Board of Education is indispensable for the medical officer seeking accommodation for an abnormal child, whether deaf, blind, epileptic, crippled, delicate, mentally defective, tuberculous, or otherwise defective. This information is given in Part I.; Part II. contains a list of institutions providing higher education for blind, deaf, defective, and epileptic children; Part III. enumerates the recognised nursery schools. The number of schools has not materially altered since the last edition of the list (see THE LANCET, 1930, ii., 308); there are a few additions resulting from adaptation of buildings taken over from the old poor-law and considerably more nursery schools. As before, a school maintained by one authority in the area of another authority is entered under the latter, but is also given under the authority maintaining it—e.g., the L.C.C. residential school for the deaf at Anerley is entered under Kent (Penge), but is also given under the London special schools. A glance through the list still reveals the great lack of accommodation for the epileptic and the children with combined defects, otherwise in many areas the provision is nearly adequate. The booklet may be obtained from H.M. Stationery Office or through any bookseller (Pp. 48. 9*d*.).

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED APRIL 14TH, 1934

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 3 (last week 6); scarlet fever, 2652; diphtheria, 1000; enteric fever, 24; acute pneumonia (primary or influenzal), 1485; puerperal fever, 61; puerperal pyrexia, 129; cerebro-spinal fever, 28; acute polio-myelitis, 1; encephalitis lethargica, 10; dysentery, 10; ophthalmia neonatorum, 87. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on April 23rd–24th was as follows: Small-pox, 11 under treatment, 1 under observation (last week 1 and 7 respectively); scarlet fever, 1579; diphtheria, 1703; measles, 3420 (last week 3648); whooping-cough, 302; puerperal fever, 37 mothers (plus 12 babies); encephalitis lethargica, 259; poliomyelitis, 4; "other diseases," 116. At St. Margaret's Hospital there were 16 babies (plus 6 mothers) with ophthalmia neonatorum.

Deaths.—In 118 great towns, including London, there was no death from small-pox, 2 (0) from enteric fever, 155 (63) from measles, 22 (6) from scarlet fever, 48 (13) from whooping-cough, 41 (8) from diphtheria, 46 (14) from diarrhœa and enteritis under two years, and 111 (24) from influenza. The figures in parentheses are those for London itself.

Measles is again slightly on the wane. This week there were 11 fatal cases in Liverpool, 8 in West Ham, 7 in Middlesbrough, 6 in Barnsley, 5 each in Newcastle-on-Tyne and Salford, 4 in Dagenham. Bournemouth and Salford each reported one death from enteric fever. Whooping-cough caused 12 deaths in Liverpool, 3 each in Sheffield and Birmingham. Fatal cases of influenza were widely distributed among 48 great towns, the highest number of deaths being reported from Birmingham 15, Liverpool 10.

The number of stillbirths notified during the week was 303 (corresponding to a rate of 42 per 1000 total births), including 41 in London.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Bills Advanced

IN the House of Commons on Friday, April 20th, the Registration of Births, Deaths and Marriages (Scotland) (Amendment) Bill passed the report stage and was read the third time.

The Workmen's Compensation (1925) Amendment Bill (which provides for the security of colliery workers in respect of claims for workmen's compensation in cases where the employers become bankrupt) was read the third time.

On Monday, April 23rd, the Birmingham United Hospital Bill was read a second time.

HOUSE OF COMMONS

WEDNESDAY, APRIL 18TH

Foreign Milk and Milk Products

Mr. WILLIAM MORRISON asked the Minister of Agriculture the actual restrictions now in force with regard to the importation of foreign skimmed and full-cream condensed milk, sterilised cream, and milk powder.—Dr. BURGIN (Parliamentary Secretary to the Board of Trade) replied: The foreign governments mainly concerned with the export of condensed milk, milk powder, and cream to the United Kingdom have been asked by His Majesty's Government to make reductions as follows in such exports as from April 1st, the reductions proposed being in each case based on the imports during the same months of the year previous to the introduction of the voluntary arrangements—namely, June, 1932, to May, 1933:—

Condensed skimmed milk.—Reduction of 22½ per cent. for the quarter ending June 30th.

Cream.—Reduction of 30 per cent. for the quarter ending June 30th.

Condensed whole milk and milk powder.—Reduction of 20 per cent. for the time being. The Government has every hope that these proposals will be agreed to.

Imports of condensed milk, milk powder, and cream from foreign countries are also subject to the following customs duties: Condensed whole milk and milk powder, unsweetened, *six shillings* per cwt.; *condensed whole milk*, sweetened, five shillings per cwt., in addition to any duty payable on the sugar content; condensed skimmed milk and milk powder, sweetened, 10 per cent. ad valorem, or the duty payable upon the sugar content, whichever is the larger; cream, 10 per cent. ad valorem.

THURSDAY, APRIL 19TH

Children and Health Insurance

Mr. RHYS DAVIES asked the Minister of Health what reply had been returned to the representations he had received expressing the desire that young persons should, on entering employment after leaving school, be brought within the scope of national health insurance as in the case of young persons under the provisions of the Unemployment Bill now before Parliament.—Mr. SHAKESPEARE (Parliamentary Secretary to the Ministry of Health) replied: My right hon. friend has promised to give the matter careful consideration, but has been obliged to point out the serious financial difficulties which make it impracticable to adopt the proposal at the present time.

Mr. DAVIES: Is the hon. gentleman aware that employers in many parts of the country dismiss boys and girls from their employment when they arrive at the age of 16 because of the contribution to the national health insurance scheme; and in view of the fact that the Unemployment Bill gets over that difficulty in respect of unemployment insurance, will the hon. gentleman look into the subject once more?

Mr. SHAKESPEARE: We have it in mind.

Poor Relief in England and Wales

Mr. **Tom Smith** asked the Minister of Health the number of persons in receipt of poor relief in England and Wales on the last available date, giving separate figures for men, women, and children, and comparable figures for the same period during the past three years.—Mr. **Shakespeare** replied: The total numbers of persons (men, women, and children) in receipt of poor relief in England and Wales (excluding rate-aided patients in mental hospitals, persons in receipt of domiciliary medical relief only, and casuals) on Saturday, March 24th, 1934, and on the corresponding days in 1933, 1932, and 1931 were 1,413,780, 1,357,236, 1,188,077, 1,038,432 respectively. The weekly returns from which these figures have been obtained do not distinguish the numbers of men, women, and children. These particulars can only be obtained from the annual returns as to poor relief on Jan. 1st, and the figures are as follows:—

—	Total persons in receipt of poor relief (excluding rate-aided patients in mental hospitals).			
	Men.	Women.	Children.	Total.
Jan. 1st, 1931 .	288,825	372,237	353,871	1,014,933
,, 1932 .	332,287	406,844	403,894	1,143,025
,, 1933 .	406,708	470,733	498,204	1,375,645
,, 1934 .	420,686	481,661	500,378	1,402,725

Effect of Fire Maroons on Nervous People

Mr. **Hutchison** asked the Home Secretary whether, in order to put an end to the obsolete system of summoning fire brigades by firing maroons whereby much suffering was caused to nervous people, he will circularise local authorities recommending the installation of telephones to ensure that the brigade presented itself promptly on an outbreak of fire.—Sir **John Gilmour** replied: The objections to maroons or sirens as a means of summoning a fire brigade are, I think, generally recognised, but neither I nor my right hon. friend the Minister of Health would feel justified in urging on the smaller brigades the expenditure which the provision of telephones or bells to firemen's houses would entail.

Imports of Milk and Milk Products

Mr. **William Morrison** asked the President of the Board of Trade how much was imported from foreign countries in the months of March, 1933, and March, 1934, of the following substances: skimmed condensed milk, full cream condensed milk, sterilised cream, and milk powder.—Dr. **Burgin** replied: The following table shows the total quantity and declared value of the undermentioned commodities imported into the United Kingdom and registered during March, 1933 and 1934, as consigned from foreign countries.

Description.	March, 1933.		March, 1934.	
	Quantity.	Declared value.	Quantity.	Declared value.
	Cwts.	£	Cwts.	£
Condensed milk—				
Separated or skimmed ..	174,257	177,189	138,919	195,619
Whole	33,982	59,459	27,736	51,935
Cream: fresh ..	6,732	19,917	63	205
Other, including cream in air-tight containers			3,572	11,778
Milk powder ..	4,989	6,233	5,419	6,628

Note.—Particulars of the imports of sterilised cream, included under "cream" in the above table, are not separately recorded in the trade returns of the United Kingdom.

MONDAY, APRIL 23RD

Indian Medical Services

Dr. **John Williams** asked the Secretary of State for India whether the proposal made in the Council of State that recruitment to the Indian medical services should be by simultaneous competitive examination in India had been agreed to by His Majesty's and the Government of India.—Sir S. Hoa The resolution on this subject in the Counci was withdrawn after the Government spokes given reasons why the Government of India c accept it and after an undertaking had been give the debate would be forwarded to me. I have n received any observations from the Government of on the matter.

Dr. **John Williams** asked the Secretary of State India whether he would state the relative proportion Indians to Europeans now serving in the Indian Medica Service.—Sir S. **Hoare** replied: According to information available on March 1st the actual strength of the Indian Medical Service was 385 British officers and 240 Indian officers; 29 of the latter held temporary commissions.

Diseases of Animals Act

Mr. **Glossop** asked the Minister of Agriculture if he was aware that a large consignment of pigs from Sweden to Canada were going to be transhipped within the port of London: and whether steps would be taken to prevent any contravention of the Diseases of Animals Act, which prohibited the bringing of live pigs and other animals to this country from the Continent of Europe.—Mr. **Ormsby Gore** (First Commissioner of Works) replied: Yes, Sir. My right hon. friend has provisionally agreed to authorise this transhipment under conditions prescribed by him and no contravention of the Diseases of Animals Act will be involved.

TUESDAY, APRIL 24TH

Suicides through Gas-stoves

Mr. **Leckie** asked the President of the Board of Trade whether, in view of the increasing number of suicides through gas stoves, he would make inquiries as to the practicability of introducing into coal-gas at the place of manufacture some pungent or disagreeable chemical agent which would render it more difficult for anyone attempting suicide in this way to do so.—Mr. **Runciman** replied: The practicability of introducing irritant or odorous material other than that provided for in the Gas (Carbon Monoxide) Order of 1922 was considered by the Committee on Deaths from Gas Poisoning in 1930, but after reviewing the objections to such addition the Committee decided to make no recommendation in this respect. In accordance with another recommendation a central advisory committee was set up by the industries concerned and I am satisfied that this committee would acquaint me with any development which would render further action practicable.

Milk-supplies to Military Hospitals

Lieut.-Colonel **Heneage** asked the Financial Secretary to the War Office whether the contracts of the hospitals under his control required the purchase of certified, grade A, or ordinary standard milk.—Mr. **Duff Cooper** replied: Tenders are invited for fresh and for pasteurised milk for hospitals, but not for certified or grade A milk. The fresh milk has to comply with the Department's specification and is required to be not below the standard required by the Sale of Milk Regulations, 1901. Unless the cost is excessive, preference is invariably given to pasteurised milk, and this type of milk is being supplied to the majority of military hospitals under the existing contracts.

New Formulæ for Surgical Spirit

Miss **Horsbrugh** asked the Secretary of State for Scotland if he would state on behalf of which local authorities in Scotland he had received representations during the last six months concerning the drinking of methylated spirits and the necessity for further restrictions on its sale; and what action he proposed to take.—Mr. **Skelton** replied: During the last six months, representations in favour of legislation to prohibit or prevent the sale of methylated spirits or kindred spirits for human consumption have been made to my right hon. friend on behalf of the town councils of Aberdeen, Clydebank, Dundee, Edinburgh, Falkirk, Glasgow, Greenock, Inverness, Paisley and Stirling. As from March 15th, 1934, new formulæ for surgical spirit have been brought into operation by the ommissioners of Customs and Excise. It is hoped that ese will render surgical spirit undrinkable, and it is roposed to await the results of this experiment before onsidering whether further measures restricting the sale of methylated and surgical spirits are necessary.

Miss **Horsbrugh** asked if the hon. gentleman would take steps to restrict the sale of methylated spirit which would not be affected by the new formulæ for surgical spirit.

Mr. **Skelton**: I will consider that question.

Blood-tests as Evidence of Paternity

Sir **Francis Fremantle** asked the Home Secretary (1) whether he was aware that, in a recent case of disputed paternity, both parties agreed to accept a blood-test as evidence, and that the magistrates decided the case without such evidence; and whether he would consider the advisability of securing the admission of such evidence on the requisition of either party with retrospective effect, and (2) whether he was aware that blood-tests were accepted in several countries as normal evidence of non-paternity; that this evidence was found to be conclusive in one out of three cases of actual non-paternity; and whether he would take the necessary steps to make such proof admissible in the English courts.—Sir J. **Gilmour** replied: I am advised that if evidence with regard to a blood-test is available, such evidence is admissible under the existing law in this country. Such difficulties as exist appear to be rather of a practical than of a legal character and to arise from the fact that the cost of arranging for such a test would fall on the man concerned and that he would have to secure the coöperation of the woman. I am giving my careful consideration to the whole matter, but if there were any question of compelling persons to submit to a blood-test, legislation would be required for this purpose.

Sir F. **Fremantle** asked if it would be possible for the Home Office to make the fact known to the magistrates of the country that they might accept this evidence, which at present they were refusing.

Sir J. **Gilmour**: I think there is no question that the magistrates are fully aware of that point.

Sir F. **Fremantle** asked whether in cases where magistrates had refused such evidence it would be possible for the case to be reopened.

Sir J. **Gilmour**: No sir. It would be for the magistrates to sum up what was the value of such evidence.

Slum Clearance and Rehousing

Sir **Percy Harris** asked the Minister of Health how many persons in England and Wales displaced by slum-clearance schemes during the last 12 months had been rehoused.—Mr. **Shakespeare**, Parliamentary Secretary to the Ministry of Health, replied: The rehousing accommodation provided during the year ended March 31st, 1934, to replace houses demolished under the Housing Act, 1930, or to abate overcrowding in Improvement areas, was sufficient for the accommodation of 42,888 persons.

MEDICAL NEWS

University of Cambridge

The title of the degree of M.D. has been conferred on Dr. Kathleen Muir.

University of London

At recent examinations the following candidates were successful:—

DIPLOMA IN PSYCHOLOGICAL MEDICINE

With Special Knowledge of Psychiatry.—Winifred M. Burbury, M.B., B.S., A. B. Carter, Bernard Cates, M. S. Jones, and W. G. Rees.

With Special Knowledge of Mental Deficiency.—R. M. Bates.

Part A.—R. W. Maxwell, Grace H. Thomson, W. P. Berrington, Neil McDiarmid, W. E. McIlroy, and David Prentice.

At recent examinations at the London School of Hygiene and Tropical Medicine the following candidates were successful:—

D.P.H.

Part I.—O. M. T. Ansari, W. H. Crichton, F. R. Dennison, H. A. Dirckze, Margaret L. Foxwell, Muriel O. Gibson, G. S. C. de S. Gunesekera, Ellen G. Heycock, F. E. Lipscomb, F. J. G. Lishman, G. H. Lowe, G. P. McC. Marshall, K. J. G. Milne, D. D. Payne, Ethel A. Perrott, C. D. Preston, Alison J. Rae, Llywelyn Roberts, L. B. E. Seneviratne, Mary Sutcliffe, L. G. W. Urich, and S. L. Wright.

Three lectures on experimental vertebrate embryology will be given at University College, Gower-street, W.C., at 5.15 P.M. on May 22nd, 24th, and 25th by Prof. W. Vogt of Zurich. Prof. J. P. Hill, F.R.S., will take the chair at the first lecture. Admission will be without ticket.

Geoffrey Duveen Travelling Studentship.—Applications are invited from medical graduates of the University for this studentship. It is of the value of £450 per annum, and it will be awarded to a research worker in oto-rhino-laryngology. Applications should reach the academic registrar of the University, South Kensington, S.W.7, before June 11th.

Research Funds.—Applications are invited for grants from the Thomas Smythe Hughes and Beaverbrook medical research funds, which are allocated for the support of original medical research. Grants may also be made from the Dixon fund for assisting scientific investigations. The latest date for application is May 15th, and particulars may be had from the academic registrar.

Royal Institute of Public Health

The final programme of the annual congress, to be held in Norwich from Tuesday, May 15th, to Whit-Sunday, the 20th, has now been issued. Application for membership should be made to the hon. secretaries of the institute, 23, Queen-square, London, W.C.1.

Society of Apothecaries of London

At recent examinations the following candidates were successful:—

Surgery.—A. E. Ginn, Guy's Hosp.; G. W. Hardy, St. Mary's Hosp.; R. G. Joyce, St. Bartholomew's Hosp.; H. Murkus, Univ. of Birmingham; D. Rocyn-Jones, Welsh National School of Medicine.

Medicine.—S. Grodd, St. Mary's Hosp.; H. G. Howitt, London Hosp.; L. A. Lewis, King's College Hosp.; T. Morgan, Guy's Hosp.; F. D. Paterson and J. H. Playne, St. Mary's Hosp.; P. H. Willcox, Univ. of Cambridge and St. Mary's Hosp.

Forensic Medicine.—P. T. M. Clarke, Middlesex Hosp.; S. Grodd, St. Mary's Hosp.; B. S. Minden, St. George's Hosp.; J. R. Owen, Univ. of Cambridge and St. Mary's Hosp.; F. D. Paterson, St. Mary's Hosp.

Midwifery.—J. A. Carter, Univ. of Cambridge and London Hosp.; S. Klein, Univ. of Vienna and St. Mary's Hosp.; J. E. T. Munn, St. Mary's Hosp.; C. W. O'Donoghue, London Hosp.; F. D. Paterson, St. Mary's Hosp.; D. Walton, Univ. of Manchester; J. P. Walsh Conway, Charing Cross Hosp.

The following candidates, having completed the final examination, are granted the diploma of the society entitling them to practise medicine, surgery, and midwifery: S. Grodd, T. Morgan, F. D. Paterson, J. H. Playne, J. P. Walsh Conway, and P. H. Willcox.

University of Glasgow

On April 21st the following degrees were conferred:—

M.D.—I. M. Christie and Harold Fairbairn (with high commendation); James Flind, S. I. A. Laidlaw, and Peter Shannon (with commendation); Alexander Duff, G. G. Macphee, N. McE. Montgomery, Archibald Ogg, Thomas Paton, H. S. Russell, A. G. Smith, Jean W. Symington, and R. N. Walker.

M.B., Ch.B.—E. W. Walls (with honours); Adam Muir (with commendation); J. M. Anderson, C. Arak, A. Cameron, D. Campbell, J. Campbell, W. Clark, J. M. Cook, R. G. H. Cunningham, Elizabeth M. Deighton, J. C. Fitch, C. M. Fraser, W. Gibson, J. Gilmour, W. Guthrie, Jean A. Holburn, A. S. Hutcheson, A. B. Kabnick, J. Kelly, S. M. Laird, C. M. Lamont, Jean H. M. Laurie, Magdalene Linton, S. Loman, A. M. McArthur, A. D. MacArthur, K. MacColl, Jeanie J. Macdonald, Maud P. MacDougall, S. W. MacDougall, D. Macfarlane, P. A. M. Macgregor, J. Mackenzie, M. J. McLaughlin, W. B. McLean, J. McPheat, T. J. R. Miller, N. Morison, W. W. Muir, J. Murray, S. S. Naftalin, J. S. Norwell, G. A. F. Quinnell, H. J. Reid, Jessie V. M. Robb, W. Rodger, R. L. Roxburgh, J. B. Shiel, E. I. Smith, Margaret B. Steel, J. N. R. Stephen, J. W. Strachan, J. C. Taylor, R. B. Taylor, Kathleen M. Warren, H. Weir, G. Wotherspoon, D. D. Young, and B. Zahb.

Queen's University Club, London

The annual spring dinner of this club will be held at the Dorchester Hotel, W., on Thursday, May 3rd, at 7.30 P.M., with Prof. R. M. Henry in the chair. Members may obtain tickets from the hon. secretaries at 101, Harley-street, W.1.

A Department of Industrial Medicine

The University of Birmingham has decided to institute a department of industrial hygiene and medicine, and arrangements are being made for its opening next October. The function of the department will be to undertake research in the application of medicine to industry, and to offer a special training to doctors who are whole- or part-time medical officers to industrial organisations or who wish to qualify for such posts. It is felt that Birmingham will be an ideal centre for such work, and the university will probably arrange to grant a diploma to those who complete the course of training successfully.

Dental Travelling Scholarship

Guy's Hospital dental school offers a travelling scholarship worth £250 to enable the holder to take out a course of at least six months' practical work in dental surgery at one or more colonial or foreign dental schools. Particulars were given in our advertisement columns last week (April 21st). Applications should be sent to the dean, Guy's Hospital dental school, London, S.E.1, not later than May 24th.

West End Hospital for Nervous Diseases

The Savill prize is offered biennially to a post-graduate student for a thesis on a neurological subject. Candidates must have attended the practice of the hospital, and must submit the subject of their choice to the examiners before May 31st. The thesis must be received by Nov. 30th. The value of the prize is £15, and communications should be addressed to the secretary of the hospital, Welbeck-street, London, W.1.

Hospital for Sick Children

A post-graduate course on diseases of children will be held at this hospital from April 30th to May 12th. Particulars will be given weekly in our Medical Diary. Applications should be addressed to the secretary of the hospital, Great Ormond-street, London, W.C.1.

Clinical assistants.—There are a few vacancies at the hospital for clinical assistants to the physicians to out-patients. Practitioners registered in Great Britain who are willing to give their services for a few hours on one or two mornings each week should communicate with the secretary of the hospital.

Light and Heat Exhibition and Conference

In connexion with the Hospital Equipment Exhibition and Conference which will be held this year at Grosvenor House, London, W., there will be a section devoted to light, heat, and massage in relation to medicine and surgery. The exhibition will be opened on April 30th, at 2 P.M., by Princess Marie Louise, and later in the same day papers will be read by Dr. William Brown, on the healing touch (2.30 P.M.), and Sir W. Arbuthnot Lane, on diet and race (6.30 P.M.). Speakers on subsequent days will be Mr. J. D. Magor Cardell (May 1st), Sir Kenneth Goadby, Mr. Cecil Voge, Ph.D., and Mrs. Marie Stopes, D.Sc. (May 2nd), Dr. J. Russell Reynolds and Mr. G. W. C. Kaye, D.Sc. (May 3rd), and Dr. C. W. Buckley and Dr. F. Howard Humphris (May 4th).

Royal Sanitary Institute

Sir Hilton Young, the Minister of Health, will address a special session of the health congress of this institute, which is to be held at Bristol from July 9th to 14th. The title of his address will be Some Aspects of the Housing Question. It is expected that 1400 persons will be present at the congress, and an elaborate programme has been prepared. In the health exhibition connected with the meeting will be found appliances, foods, and other exhibits illustrating municipal activities and the hygiene of the home. Particulars may be had from the secretary of the institute, 90, Buckingham Palace-road, London, S.W.1.

As a memorial to the late Prof. A. Bostock Hill, M.D., the council has decided to offer for annual award a challenge shield for the best celebration of Health Week in the Empire, outside the British Isles. Health Week this year will be from Oct. 7th to 13th, and overseas centres wishing to enter the competition must submit reports by Dec. 31st.

Royal Eye Hospital

This hospital in St. George's Circus, Southwark, closed 1933 with a credit balance of £1236. There were increases in annual subscriptions and donations, but they are still inadequate. The report emphasises the need for a rebuilding scheme estimated to cost £150,000. It is intended shortly to issue a public appeal.

Medical Diary

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, May 1st.

Orthopædics. 5.30 P.M. Annual General Meeting. Cases at 4.30 P.M.

Special Meeting of Fellows. 8 P.M. Demonstration by Dr. Russell Reynolds on X-ray Cinematography. Dr. Robert Janker (Bonn) will also show films. Admission by ticket only.

WEDNESDAY.

History of Medicine. 5 P.M. Annual General Meeting. Dr. Herbert R. Spencer: The History of Ovariotomy.

Surgery. No meeting of the Section on this day.

THURSDAY.

Tropical Diseases and Parasitology. 8 P.M. Special Meeting to consider regulations of the section. 8.15 P.M. Annual General Meeting. Dr. H. S. Stannus: The Hyperostoses of the Face and Cranium (Epidiascope).

FRIDAY.

Otology. 10 A.M. Annual General Meeting. Cases at 9.30 A.M. Dr. Albert A. Gray: The Otosclerosis Problem (Dalby lecture). Demonstration: Valve Amplifier Hearing Aids (Audiograph).

Laryngology. 5 P.M. Annual General Meeting. Cases at 4 P.M.

Anæsthetics. 8.15 P.M. Annual General Meeting. 8.30 P.M. Dr. R. J. Minnitt: Self-administered Analgesia for the Midwifery of General Practice (illustrated by film).

Obstetrics and Gynæcology. Members of this Section invited.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, May 4th.—8.30 P.M. (at the West London Hospital). Mr. A. Tudor Edwards: Malignant Disease in the Chest.

BIOCHEMICAL SOCIETY.

SATURDAY, May 5th.—2.30 P.M. (in the Department of Biochemistry, Oxford). Communications and Demonstrations.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W. TUESDAY, May 1st, and following Thursday.—5 P.M., Dr. C. H. Andrewes: Viruses in Relation to the Ætiology of Tumours (Oliver-Sharpey lectures).

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.

MONDAY, April 30th, to SUNDAY, May 6th.—MAUDSLEY HOSPITAL, Denmark-hill, S.E.5. Course in Psychological Medicine. Afternoons.—ST. JOHN'S HOSPITAL, Leicester-square, W.C. Course in Dermatology. Afternoons.—CITY OF LONDON HOSPITAL, Victoria-park, E. Course in Cardiology. All day, Sat. and Sun.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W. Dr. A. E. Clark-Kennedy: Lecture on Auricular Fibrillation, at 2.30 P.M., on Tues. Thurs., at 4 P.M. The Skin in Relation to Rheumatism in Childhood and After Puberty, read by Dr. F. Fraser-Harris on behalf of the late Dr. Ll. J. Llewellyn.—PANEL OF TEACHERS. Individual clinics in various branches of medicine and surgery are available daily by arrangement with the Fellowship of Medicine. Courses of instruction, clinics, &c., arranged by the Fellowship of Medicine are open only to Members and Associates.

ST. PAUL'S HOSPITAL, Endell-street, W.C.

WEDNESDAY, May 2nd.—4.30 P.M., Mr. Kenneth Walker: Functional Disorders of the Genito-Urinary System.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.

MONDAY, April 30th. to SATURDAY, May 5th.—Third Week of Intensive Course in Laryngology, Rhinology, and Otology.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.

WEDNESDAY, May 2nd.—3.15 P.M. (at the Royal Chest Hospital, City-road), Dr. Peter Kerley: Radiology of the Cardiovascular System.

THURSDAY.—3.15 P.M., Dr. E. G. B. Calvert: Functional Disorders of the Gastro-intestinal Tract.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL, Denmark-hill, S.E.

THURSDAY, May 3rd.—4.30 P.M., Colonel L. W. Harrison: Prevention of Venereal Disease.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

(First of 2 Weeks' Course.)

MONDAY, April 30th.—10 A.M., Dr. Hutchison: Ward Visit. 11 A.M., Mr. Lloyd: Tuberculosis of Bones and Joints. 12 noon, Dr. Sheldon: Pulmonary Tuberculosis. 2 P.M., Dr. Thursfield: Ward Visit. 3 P.M., Dr. Nabarro: Immunisation against Diphtheria, Measles, and Scarlet Fever.

TUESDAY, May 1st.—10 A.M., Dr. Shires: Diseases of the Bones. 11 A.M., Dr. Cockayne: Ward Visit. 12 noon, Dr. Pearson: The Breast-fed Infant. 2 P.M., Dr. Frew: Ward Visit. 3 P.M., Dr. Payne: Diabetic Coma.

WEDNESDAY.—10 A.M., Dr. Gray: Diseases of the Skin. 11 A.M., Dr. Paterson: Treatment of Pneumonia. 12 noon, Mr. Addison: Ward Visit. 2 P.M., Dr. Hawksley: Diagnostic Use of the Blood Count. 3 P.M., Dr. Signy: Treatment of Septicæmia.

THURSDAY.—10 A.M., Dr. Wyllie: Cerebral Paralysis. 11 A.M., Mr. Tyrrell-Gray: Ward Visit. 12 noon, Dr. Sheldon: Rickets. 2 P.M., Dr. Thursfield: Ward Visit. 3 P.M., Mr. Crooks: Nasal Catarrh and Sinusitis.

FRIDAY.—10 A.M., Dr. Cockayne: Ward Visit. 11 A.M., Mr. Barrington-Ward: Ward Visit. 12 noon, Dr. Pearson: The Bottle-fed Infant. 2 P.M., Dr. Frew: Ward Visit. 3 P.M., Dr. Bruce Pearson: Treatment in Hay-fever and Asthma.

SATURDAY.—10 A.M., Dr. Paterson: The Anæmic Child. 11 A.M., Mr. Penman: Inflammatory Conditions of the Eye. 12 noon, Mr. Browne: Ward Visit.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.

DAILY.—2 P.M. Operations, Medical and Surgical Clinics.

MONDAY, April 30th.—10 A.M., Skin Clinic, Medical Wards. 11 A.M., Surgical Wards. 2 P.M., Gynæcological and Surgical Wards, Eye and Gynæcological Clinics.

TUESDAY, May 1st.—10 A.M., Medical Wards. 11 A.M., Surgical Wards. 2 P.M., Throat Clinic. 4.15 P.M., Lecture, Mr. Green-Armytage: Uterine Inertia and Uterine Spasm.

WEDNESDAY.—10 A.M., Medical Wards, Children's Ward and Clinic. 2 P.M., Eye Clinic.

THURSDAY.—10 A.M., Neurological and Gynæcological Clinics. 11.30 A.M., Fracture Clinic. 2 P.M., Eye and Genito-urinary Clinics.

FRIDAY.—10 A.M., Skin Clinic. 12 noon, Lecture on Treatment. 2 P.M., Throat Clinic. 4.15 P.M., Lecture, Dr. Konstam: Microcytic Anæmia.

SATURDAY.—10 A.M., Medical and Surgical Wards, Children's and Surgical Clinics.

The Lectures at 4.15 P.M. are open to all medical practitioners without fee.

ST. MARY'S HOSPITAL INSTITUTE OF PATHOLOGY AND RESEARCH, Paddington, W.

THURSDAY, May 3rd.—5 P.M., Sir Bernard Spilsbury: Applications of Physiological Principles to Medico-Legal Problems.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY, May 1st.—5 P.M., Dr. H. W. Barber: Alopecia Areata and Vitiligo.

WEDNESDAY.—5 P.M., Dr. H. Corsi: Diseases of the Nails.

THURSDAY.—5 P.M., Dr. S. E. Dore: Lantern or Epidiascope [illegible] Skin Diseases.

FRIDAY.—[illegible]: Skin Diseases due to Prot[illegible]

MANCHESTE[illegible]

TUESDAY, [illegible] B. Leech: Colitis.

FRIDAY.—[illegible]: Demonstration of Neuro-surgical Cases.

UNIVERSITY OF BIRMINGHAM.

TUESDAY, May 1st.—3.30 to 5 P.M. (at the General Hospital), Dr. E. W. [illegible]ment of Prostatitis. [illegible] Cases.

WEDNESDAY.—4 [illegible] of the Medical Fac[illegible] Adrian: The Activity of Nerve-cells. (Last of two Lectures.)

THURSDAY.—4 P.M., Dame Louise McIlroy: The Toxæmias of Pregnancy. (Last of two Ingleby Lectures.)

FRIDAY.—3.30 to 5 P.M. (at the Queen's Hospital), Prof. Bertram Lloyd: Surgical Cases.

LEEDS GENERAL INFIRMARY.

TUESDAY, May 1st.—3.30 P.M., Prof. A. M. Claye: Demonstration in Gynæcological Cases.

GLASGOW POST-GRADUATE LECTURES.

WEDNESDAY, May 2nd.—4.15 P.M. (at the Royal Hospital for Sick Children), Dr. S. Graham: Medical Cases.

Appointments

BAILEY, K. V., M.D. Manch., M.R.C.P. Lond., M.C.O.G., has been appointed honorary gynæcologist to the Stockport Infirmary.

BEAUMONT, E. V., M.B., B.S. Lond., Certifying Surgeon under the Factory and Workshop Acts for the Brandon District of the County of Suffolk.

KLETZ, NORMAN., [illegible] M.R.C.P. Lond., honorary assistant physic[illegible] Royal Infirmary.

STARKEY, J. W., M.[illegible] l., Medical Officer of Health, Colne, Lancs.

SUTHERLAND, DONALD MCKAY, M.D. Manch., F.R.C.S. Eng., honorary assistant surgeon to the Manchester Royal Infirmary.

Vacancies

For further information refer to the advertisement columns

Aberdeen Royc' [illegible]

Ashton-under-[illegible] £300.

Birmingham, [illegible]

Birmingham, Yardley Green-road Sanatorium.—Jun. M.O. At rate of £200.

Birmingham, Selly Oak Hospital.—Cas. O. At rate of £200.

Birmingham University.—Lecturer in Bacteriology. £400.

Bolingbroke Hospital, Wandsworth Common, S.W.—H.S. At rate of £120.

Bridgend, Glamorgan County Mental Hospital.—Jun. Asst. M.O. £350.

Cambridge, Addenbrooke's Hospital.—H.P. At rate of £130.

Cancer Hospital, Fulham-road, S.W.—Laryngologist.

Central London, Throat, Nose, and Ear Hospital, Gray's Inn road, W.C.—3rd Res. H.S. At rate of £75. Also Hon. Assts. in the Out-patient Dept.

Chichester, Royal West Sussex Hospital.—Sen. and Jun. H.S. £175 and £125 respectively.

Coventry and Warwickshire Hospital.—H.S. (Male). Also Cas. O. (Male). Both at the rate of £125.

French Hospital and Dispensary, 172, *Shaftesbury-avenue, W.C.*—Hon. Dermatologist.

Harrow U.D.C.—M.O.H. £1000.

Hospital for Sick Children, Great Ormond-street, W.C.—Physician to Out-patients. Also Surgeon; and Clin. Assts. to Physicians to Out-patients.

Ilford, King George Hospital.—Deputy Res. M.O. £200. Also H.S. At rate of £100.

Liverpool Port Sanitary Authority.—Asst. Port M.O. £700.

London County Council.—Asst. M.O. £600.

London Homœopathic Hospital, Great Ormond-street, W.C.—Res. M.O. £100.

Sunderland Royal Infirmary.—H.S. £200.

Swanley, Kent, White Oak Hospital.—Res. M.O. At rate of £200.

Swansea County Borough.—Asst. M.O. £500.

West London Hospital, Hammersmith-road, W.—Hon. Dermatologist. Also Hon. Asst. Anæsthetist.

Westminster Hospital, Broad-sanctuary, S.W.—H.S. to Spec. Depts. At rate of £104.

Will Edmonds' Clinical Research Fund.—Fellowship. £500.

Winchester, Royal Hampshire County Hospital.—Res. Surg. O. At rate of £200.

Windsor, King Edward VII. Hospital.—Hon. Asst. Surgeon.

Wolverhampton and Midland Counties Eye Infirmary.—H.S. £150.

Wolverhampton, Royal Hospital.—H.S. At rate of £100.

NOTES, COMMENTS, AND ABSTRACTS

BUDGET RELIEF ON SMALL INCOMES

Mr. W. T. Fry, income-tax consultant (13, Buckingham Palace-gardens, London, S.W.1), writes: "Although the Budget gave some measure of relief to income-tax payers the man with a small income is still overburdened. It is to be hoped that next year the Chancellor will be able to restore the abatements which were in force prior to the emergency Budget of 1931. Some idea of the position is given by the following figures, which show the tax payable on an earned income of £650 by a man with family responsibilities:—

	1933–34. £ s. d.	1934–35. £ s. d.	1930–31. £ s. d.
Single man with widowed mother to support	76 17 6	69 3 9	54 12 6
Married man	70 12 6	63 11 3	40 0 0
Do. with 1 child	58 2 6	52 6 3	26 10 0
Do. with 3 children	38 2 6	34 6 3	15 13 4

From the above examples it will be seen that the relief given by the Budget is very small, and for this reason it is essential that the return forms which are now being issued should be completed with the greatest care and all possible abatements claimed."

A SEVERE WINTER FOR ANIMALS IN CAPTIVITY

THE Zoological Society's country home at Whipsnade has been showing increasingly the extent to which non-native animals can live an open-air life in this country, but the spell of cold weather at the beginning of last winter was a trying time both there and in Regent's Park. At Whipsnade the chief losses were four alligators, two nylghaie, four Canadian beavers, two axis deer, a tiger, a bison, a sloth bear, a sarus crane, and an ostrich. The report does not state whether all these animals succumbed to the cold, and indeed the experiment of keeping monkeys at Whipsnade during the winter was highly successful. A colony of 25 rhesus monkeys, provided with sheltering barrels in an enclosure around a tall oak tree in Wallaby wood, kept in extremely good health all the winter, although they killed the tree by eating all the young shoots. Moreover the two young chimpanzees who had spent the summer at Whipsnade, in a caravan provided with electric heating, stayed out the winter there and seemed to enjoy the opportunity of sun and open-air exercise even in the cold weather. In Regent's Park the cold snap and the foggy weather which preceded it played havoc in the outdoor aviaries and carried off two birds, a white crane and a cinereous vulture, both of which had been over 32 years in the collection. There was indeed a sharp rise in the incidence of respiratory disease among all classes of animals during this period, although it is gratifying to see how low has become the mortality from tuberculosis. Last year it was only 3·9 per cent. among mammals in spite of a small outbreak among coatis. The highest monkeys have kept quite free. Taken all round, the annual death-rate among acclimatised animals is only 19 per cent. for mammals and 23 per cent. for birds, among a total population of 725 and 1479 respectively.

TUBERCULOSIS AND CANCER

Two years ago Dr. Thomas Cherry, of Melbourne, read a paper[1] at the centenary meeting of the B.M.A. describing some experiments he had made in mice, which suggested that the inoculation of small doses of virulent tubercle bacilli favoured the development of tumours and intestinal ulcers. These results threw light, he thought, on the way in which the increasing death-rates from cancer approximately balance the reduction of the rates from tuberculosis. In a recent paper[2] he shows that the causes of death of the mean population aged 15–25 enumerated in England at the four census periods 1841, 1851, 1861, and 1871 are now complete to old age and those of 1881 to the age of 65. In each of the four complete sections of the population, by simply adding the deaths from phthisis and cancer and dividing the sum by the number of deaths from all causes, there is obtained an almost uniform percentage, and at the age of 65 a corresponding uniformity is found in the five series. After deducting deaths from accident from the total deaths the percentages are: for 1841 series 21·70, for 1851 series 22·16, for 1861 series 22·8, and for 1871 series 22·22. It is difficult to believe, he thinks, that these practical identities are due to coincidence. At the recent Australasian Medical Congress, held at Hobart, Dr. Cherry discussed the reliability of the earlier certificates of death. In the material he used, the deaths from cancer do not become important before 1880, because the age-groups from 15 to 45, which contribute most of the deaths from phthisis, yield only a small proportion of those due to cancer. The actual figures up to 1880 include 16,000 deaths from cancer in men and 49,000 in women. The probable error in the female deaths Dr. Cherry regards much less than in the case of males because in women a far larger proportion of cancer occurs in accessible sites.

BRONCHOSPASM AND ASTHMA

WE have received a pamphlet on this subject from the British Felsol Co., Ltd., 15, Caroline-street, London, W.C., written to bring before the medical profession the value of Felsol in the treatment of asthmatic subjects. The composition of felsol powders (already given in THE LANCET, 1928, i., 534) is as follows:—

Phenyl-dimethyl-isopyrazolone	0·47
Phenyl-dimethyl-iodopyrazolone	0·03
Anilipyrine β	0·40
Caffeine	0·10
Ext. Visci. Alb.	0·01
Ext. Brachycladii	0·01

The powders can be prescribed by the medical man in accordance with the definite régime which he decides to adopt in the treatment of a case, the claim for felsol being that its administration relieves promptly the attack of asthma by its influence over bronchial spasm, so that only the most severe cases would require the injection of morphia.

A NOISE-EXCLUDING WINDOW

ON April 19th and 20th, by invitation of the Editor of the *Parthenon*, demonstrations were given at 43, Grosvenor-place, London, of a method of noise elimination, by which, without interference with ventilation, rooms may be made sound-proof. A specially fitted room was placed at the disposal of the inventor of a patent window by the Council of the Incorporated Association of Architects and Surveyors, the window being the design of Mr. E. T. Fisk, managing director of Amalgamated Wireless of Australia Ltd. Of louvre pattern, the panes of glass open outward, while inside the room each pane is covered by a sound-absorbing blind which can be adjusted as to the height and the angle of inclination. The intention was that the sound of outdoor traffic should ascend through the openings of the window panes and be partly absorbed and partly deflected back by the blinds. The room in which the demonstrations took place was constructed with "pioneer" partitions and a shipwright floor, both patent devices intended to isolate it from noise which might emanate from adjacent apartments; but the window was exposed to the roar of the traffic in Grosvenor-place. The noise was pronounced when the sound-absorbing blinds were drawn up, and when the door of the experimental room, which opened on a balcony, was unclosed. When the door was shut and the blinds were adjusted the sound died down to an almost unnoticeable murmur. The blinds obstruct light to some extent, but sufficient is admitted for most purposes, and as regards ventilation, the window, when open, is claimed to be as effective for keeping out noise as an ordinary window when closed. The Fisk window, when closed, seems to be more sound-proof than ordinary windows. The window can be left open in driving rain without water entering the room, and the amount of dust entering the apartment from outside in dry weather is appreciably reduced by its construction. The invention is also useful as a sunshade, and ventilation is under full control. Easy fitting and low cost are other advantages claimed which should be of attraction to business firms and offices, and hospitals might particularly benefit by the adoption of the Fisk window.

A METHOD OF APPLYING TANNIC ACID TO BURNS

Dr. ARTHUR H. BENNETT (Northwich) writes: "It may be of some interest to readers to hear of a very simple method which I use to apply tannic acid to burns. Messrs. Woolley and Sons, of Manchester, have prepared for me surgical lint impregnated with tannic acid and mercuric chloride in such proportions that, when the lint is thoroughly saturated with water, it contains a 2 per cent. solution of tannic acid and 1/2000 solution of mercuric chloride. This affords a simple and convenient means of applying tannic acid to a burn, as suggested by Mr. Mitchiner, both as a first aid and as a permanent dressing. I have successfully used this method in a number of cases and the results have compared very favourably with those of others treated with fresh solution made from tablets."

A PAINLESS DRESSING FOR BURNS

Dr. E. S. Dukes (Mangonui, N.Z.) writes: The present treatment of burns is anything but satisfactory; we must all have witnessed the agony of patients during the changing of a dressing, and we know how often an anæsthetic has to be given, or a prolonged soaking, before the change can be effected. All this can be avoided by a dressing of boric-acid ointment spread upon thin rubber cloth. This never sticks, there is next to no discharge, and its removal is so painless that a child need not be awakened. The waterproof is scalded before use, and the same piece can be used again after rinsing and scalding. The wounded surface need not be washed, a new dressing being applied immediately the old is removed.

A NOTEWORTHY GOLDEN WEDDING

Mr. J. Lionel Stretton, J.P., L.R.C.P. Lond., M.R.C.S., and his wife celebrated their golden wedding on Saturday, April 21st. Mr. Stretton was present at the golden wedding celebrations of his grandfather, Mr. William Weston Stretton, J.P., and of his own father, Mr. Samuel Stretton, J.P., whom he succeeded in practice. On Saturday last Mr. and Mrs. Stretton were joined by their three children with their families. At the annual meeting of the Kidderminster and District General Hospital, of which Mr. Stretton is consulting surgeon and president, he received last year a jubilee presentation on the occasion of his completing 50 years as a member of the honorary medical staff, and in recognition of long, devoted, and valuable services. Mr. Stretton's organising abilities resulted in valuable extensions to the hospital which were opened by the Duke of York in 1926. Last December Mr. Stretton was honoured by his own profession from all parts of Worcestershire with a dinner in celebration of his 21st year as chairman of the County of Worcester Local Medical and Panel Committee, when representatives of the Ministry of Health were present. On that occasion, paying a tribute to his wife, he said, "I have the comfort of a good wife, who has helped me in my duties for the hospital, and I feel it only right that on this occasion I should refer to them." We congratulate Mr. and Mrs. Stretton in the name of the medical profession upon having followed the example of two preceding generations by celebrating a golden wedding.

THE SERVICES

ARMY MEDICAL SERVICE

Maj.-Gen. H. C. R. Hime, K.H.P., late R.A.M.C., retires on retd. pay.

Col. O. Ievers, late R.A.M.C., to be Maj.-Gen.

Lt.-Col. P. Power, from R.A.M.C., to be Col.

ROYAL ARMY MEDICAL CORPS

Maj. & Bt. Lt.-Col. M. J. Williamson to be Lt.-Col.

TERRITORIAL ARMY

Lt.-Col. W. McK. H. McCullagh, late R.A.M.C., Mila., to be Maj., and relinquishes the rank of Lt.-Col.

Capt. W. H. Gratrix resigns his commn.

Capt. F. C. Lewis relinquishes his commn. and retains his rank.

Lt. R. H. Mortis to be Capt.

Lt. G. A. F. Holloway resigns his commn.

R. W. Hendry to be Lt.

TERRITORIAL ARMY RESERVE OF OFFICERS

Maj. J. D. Fiddes having attained the age limit retires and retains his rank, with permission to wear the prescribed uniform.

Capt. G. Eager having attained the age limit retires and retains his rank, with permission to wear the prescribed uniform.

Capt. D. G. Coutts, from Active List, to be Capt.

Lt. J. Simpson, from Active List, to be Lt.

INDIAN MEDICAL SERVICE

Lts. E. H. Lossing and M. Sendak to be Capts. (provl.).

Rattan Kumar Misra and Amar Nath Duggal to be Capts. (on prob.).

Capt. B. K. Silkand resigns his temp. commn.

ROYAL AIR FORCE

Flight Lt. R. L. C. Fisher is promoted to the rank of Squadron Leader.

Births, Marriages, and Deaths

BIRTHS

NOTLEY.—On April 15th, at 105, Rockingham-road, Kettering, the wife of Dr. J. W. Notley, of a son.

RICHARDSON.—On April 20th, at 112, Highfield-lane, Southampton, the wife of L. Aylwin Richardson, F.R.C.S., of a daughter.

MARRIAGES

KENNEDY—DALES.—On April 14th, at The Priory Church, St. Bartholomew-the-Great, Smithfield, John Kennedy, F.R.C.S.I., to Sheila Freeman, only daughter of the late John Freeman Dales and Mrs. Dales, of Pentre Derwen, Oswestry.

DEATHS

CARR-CALTHROP.—On April 17th, at Croyland, Grange-road, Ealing, Middlesex, Colonel Christopher William Carr-Calthrop, C.B.E., I.M.S., J.P., aged 8[illegible] years.

LLEWELLYN.—On April 19th, Richard Ll. [illegible] Llewellyn, M.B. Lond.

LLEWELLYN.—On April 20th, at 13, Westbourne-road, Penarth, Glamorgan, Thomas Richard Llewellyn, [illegible].R.C.S., L.R.C.[illegible]., Regional M.O., South Wales, aged 64.

SPENCE.—On April 20th, at 18, Upton-road, Watford, [illegible]ry Spence, M.B. Ch.B., aged 63.

WATSON.—On April 20th, at University College Hospital, James Watson, L.R.C.P., L.R.C.S., L.D.S.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

ARC LAMP CARBONS.—Messrs. Watson and Sons (Electro-Medical), Ltd., write: "An increased import duty on arc lamp carbons was imposed by the recent Budget, which will affect the prices of foreign-made medical carbons. It has been alleged that this will mean an additional burden on our hospitals, because they could not obtain British carbons equivalent to those manufactured abroad. We wish to emphatically state that British carbon manufacturers are in no way behind their foreign competitors in respect of either the quality or range of their products."

ADDRESSES AND ORIGINAL ARTICLES

THE HORMONES AND THEIR CHEMICAL RELATIONS*

BY E. C. DODDS, M.V.O., M.D., D.Sc., F.R.C.P. Lond.
COURTAULD PROFESSOR OF BIOCHEMISTRY IN THE UNIVERSITY OF LONDON; DIRECTOR OF THE COURTAULD INSTITUTE OF BIOCHEMISTRY AT THE MIDDLESEX HOSPITAL

LECTURE I

IN the year 1914 Simmonds of Hamburg described two cases of a disease which was ultimately to bear his name (Simmonds, 1914 and 1916). The typical history and post-mortem records may be taken from the work of Riecker and Curtis (1932).

One of the patients, a woman aged 41, complained of progressive weakness and loss of weight. There was no interesting point in either the family or personal history. The patient was married at the age of 20 and had one child, who was living and healthy at the time of consultation. Menstrual periods ceased at the age of 26, whilst at 30 she noticed a lack of sweating. About this time she became very anxious concerning her appearance, since she was obviously ageing very rapidly. The sense of weakness and weariness increased, and at the age of 36 the patient suffered what she termed a stroke, which left paralysis of the right side of the face together with deviation of the right eye. At the present time she suffered from a feeling of chilliness, weakness, poor appetite, and loss of memory. Altogether she had lost some 20 lb. On physical examination the skin was atrophic, dry, and cool. There were definite signs of syphilis, but the blood pressure and reflexes were normal. The basal metabolic rate was minus 28; hæmoglobin, 90 per cent.; and the urine was free from abnormality.

The post-mortem findings from a further series of cases quoted by Riecker and Curtis show in all cases destruction of the anterior lobe of the pituitary, either by tumour or inflammatory process, together with atrophic changes in the liver, pancreas, suprarenals, thyroid, and ovaries or testes. A detailed study of all the published cases shows that this is indeed a general syndrome commencing with a destruction of the anterior lobe of the pituitary followed by subsequent degeneration of the organs mentioned above.

My first task as Goulstonian lecturer is thus completed, in spirit if not literally; for Dr. Goulston in his bequest laid down that the lectures should be illustrated—

> "on some dead body if possibly it can be procured, which shall then and there be dissected for the disease treated of, and shall afterwards be buried."

Clinical study and gross morbid anatomy must be the starting point of all medical investigation, and it was clearly the wish of the founder of these lectures that the theories propounded in them should rest on this sound foundation. In Simmonds's disease we see incontrovertible evidence that destruction of the anterior lobe of the pituitary is attended with a slow degeneration of various organs, but more particularly of the gonads, the pancreas, suprarenal, and thyroid. Taking these fundamental observations as the basis of these lectures, it is proposed to push the dissection clearly wished for by Dr. Goulston to the very finest possible limits, and I hope to be able to show you that it is now possible to carry the dissection actually down to the stage of molecular structure. By this study we shall be able to visualise the type of key that the body manufactures to open and close its various locks; and I hope also to be able to show you that it is possible for the organic chemist to manufacture keys entirely of his own design with which he can open these natural locks. And from this research it is possible to prophesy that the organic chemist and the pharmacologist are entering an entirely new field of therapeutic research.

Functions of the Anterior Pituitary

It is difficult to arrive at the first historical connexion of the anterior lobe of the pituitary as a controlling factor in the whole of the body. One may divide the earlier experiments into firstly clinical observations, secondly a study of the effects of hypophysectomy, and thirdly the effect of the administration of extract of the anterior lobe.

That the pituitary gland as a whole was involved in certain general diseases has been known for many years. The first clinical observation was that of Marie (1888) in 1886, who succeeded in establishing a connexion between the disease acromegaly and the pituitary. He was under the impression that the disease was associated with hypofunction of the gland, but to-day the reverse is held to be true. The other great clinical step in establishing the relationship of the anterior lobe of the pituitary to other organs of the body has already been referred to—namely, the study of cases of Simmonds's disease.

Turning to the question of hypophysectomy, it was early demonstrated by Paulesco (1908) that the removal of the pituitary gland as a whole is followed by death in certain animals. This was confirmed later by Cushing and his collaborators (Reford and Cushing, 1909; Crowe, Cushing, and Homans, 1910). Cushing was also able to demonstrate that partial hypophysectomy resulted in an increase of subcutaneous fat and a cessation of sexual activity (Cushing, 1909). As the result of his researches Cushing and his co-workers were definitely able to refer the sexual control to the anterior lobe of the pituitary. The greatest advances in the subject, however, were made following the perfection of methods of hypophysectomy on small animals. The first experiments with rats were made by Smith (1927,[1] 1930) in 1927. These experiments indicated quite clearly that a condition of infantilism persists if the operation be performed before puberty, and if performed after puberty, cessation of the œstrus cycle together with atrophy of the ovaries resulted. There is now an extensive literature indicating the relationship between the anterior lobe of the pituitary and the sex organs as studied by this method.

The next step was made by a study of the effect of implants of the pituitary gland. In the year 1926 Zondek and Aschheim (1927) and independently Smith (1926 and 1927[2]) published the results of implants in animals. It was shown that the implantation of pituitary into a hypophysectomised animal induced growth of follicles together with corpus luteum formation. When implanted into immature normal females the ovaries became enlarged due to growth of follicles and the formation of corpora lutea; the uterus and vagina increase in size and œstrus appears. In immature male animals the results are not so striking, but with the continuation of grafts it is found that enlargement of the testes results, and, according to some, premature spermatogenesis occurs (Voss and Loewe, 1928). According to Moore and Price (1931), however, whilst they confirm the enlargement of the seminal vesicles and prostate, there is no evidence of premature spermatogenesis.

The final proof of the relationship of the anterior lobe of the pituitary to the sex and other organs is demonstrated by the preparation of the gonadotropic hormone from extracts of the anterior lobe of the pituitary. There appears to be little doubt that the first active extracts of the pituitary gland were obtained in Evans's laboratory in 1928 (Evans and Simpson, 1928, 1929). It was shown that these extracts were capable of inducing hypertrophy of the ovary and puberty in the immature female animal.

---

* The Goulstonian lectures for 1934, delivered before the Royal College of Physicians of London on March 6th, 8th, and 13th. Lectures II. and III. will appear in forthcoming issues.

Having established the historical foundation for the doctrine of the pituitary control of the sexual cycle, it will suffice to proceed with the description of the hormones according to the state of our knowledge at the present moment, since any attempt at historical or chemical sequence would prove too lengthy.

The present-day view is that the anterior lobe of the pituitary produces the *following hormones*: (1) growth hormone; (2) prolan (A and B); (3) thyrotropic hormone; (4) pancreaticotropic hormone; (5) adrenotropic hormone; (6) parathyrotropic hormone.

With the growth hormone we are not concerned at the present time.

Prolan

Prolan is the first link between the pituitary gland and the sex organs. It passes in the blood stream to the ovary and testes and there initiates changes which are responsible for the secondary sexual characteristics. The stimulation of the testes by prolan results in the production of its own internal secretion, the male sex hormone.

THE MALE HORMONE

The study of the male sex hormone dates back very considerably, and it is indeed difficult to be certain who made the first definite experiments.

As early as 1849 Berthold (1849) succeeded in producing the familiar comb and wattles in a capon by the transplantation of testis tissue. This experimental demonstration of the stimulating action of prolan upon testis function is a striking confirmation of the experiments quoted earlier, in which it was shown that implants of the pituitary gland in immature animals produced similar activation. Perhaps the most familiar investigation is that of Brown-Séquard (1889), published in the year 1889. This much quoted research must, I fear, be regarded in the light of modern knowledge with much suspicion. It will be remembered that Brown-Séquard, then an old man, injected a simple extract of testes into himself and described very clearly a general feeling of well-being which one feels could only have been the result of suggestion. Judging from our clinical experience with other hormones, and particularly with the female sex hormone, even if Brown-Séquard's extract had contained any active testis hormone, the quantity present would have been so slight as to have no effect.

There can be little doubt that the first clear-cut experiments were made by Pézard (1911 and 1920) in the year 1911. He repeated the earlier work of Berthold and was one of the first to realise the great importance of the capon as a test object. It is a well-known fact that if the cockerel be completely caponised, the characteristic head furnishings atrophy and almost completely disappear. If a testis be grafted into such a bird, a successful operation is followed by fairly rapid growth of the comb, wattles, and the development of secondary sexual characteristics. Pézard injected intraperitoneally into his capons a preparation constituted of crushed hog cryptorchid testes for five months. The combs grew rapidly, and regressed as soon as the injections were stopped. It appears highly possible that some at least of Pézard's results were due to actual survival of the cells of hog testes, since attempts to repeat his experiments with extracts of testes in quantities similar to those he used have proved completely negative.

From 1911 onwards a series of doubtful experiments were made by a number of workers, but since we are only concerned here with the main landmarks, we must pass to the year 1927. McGee (1927) proved conclusively that an alcoholic extract of bulls' testes contained an active principle capable of causing growth in the comb. He showed that if the alcohol were evaporated off under reduced pressure, the lipins remaining were quite stable and could be injected either in aqueous suspension or in oily solution. These results were quickly confirmed by a number of workers including myself and my colleagues.

A long series of investigations were then made on the sensitivity of the comb-growth test. It is claimed by many workers that the results are quantitative, that is to say, if one injects double the quantity of hormone the comb will grow twice as long. This view has been severely attacked by Greenwood and myself, and we showed that the response is by no means quantitative, and that very large numbers of birds would have to be employed before an accurate assay could be obtained (Dodds, Greenwood, and Gallimore, 1930; Blyth, Dodds, and Gallimore, 1931).

The chemical study of the hormone could not progress to any great extent until a new source of the material other than testes could be obtained. The presence of the hormone in urine was discovered almost simultaneously and independently by a number of workers (Loewe, Voss, et al., 1928; Funk, Harrow, and Lejwa, 1930; Dodds, Greenwood, and Gallimore, 1930). All the workers quoted here investigated very carefully the chemical properties of their extracts. In my laboratory it was shown that the material could be obtained as an oil which was capable of vacuum distillation, and its properties were very similar to those of the œstrus-producing hormone. We were able to show that it would also resist saponification with alkalis such as barium hydroxide, and in addition to causing comb growth, we were able to show that the extract would produce great enlargement of the seminal vesicles as had been shown by workers with cruder extracts (Dodds, Greenwood, Allan, and Gallimore 1930).

The greatest advance in the chemistry of the compound was made by Butenandt (1931) who succeeded in obtaining a crystalline preparation by fractional distillation. He obtained a series of derivatives such as a diol and an oxyketone and he established with fair certainty that the molecule belonged to the same group as that of œstrin and the sterols. Since, however, this work *is so closely connected with that of œstrin*, I propose to leave this problem until we discuss the molecular construction of the female sex hormone (Butenandt, 1932–33).

PROLAN AND THE OVARY

To turn to the ovary, prolan passes in the blood stream from the pituitary gland to this organ and stimulates the ripening of the follicle through the characteristic stages of the corpus hæmorrhagicum followed by rupture and discharge of the ovum, subsequent conversion to corpus luteum, and final fibrosis, the corpus albicans. By the administration of prolan it is possible to demonstrate the formation of *corpora hæmorrhagica and corpora lutea*. The diagram indicates these relations (Fig. 1).

According to the views of Aschheim and Zondek, the prolan can be divided into two factors which are referred to respectively as A and B; prolan A being responsible for the formation of the corpus hæmorrhagicum, and prolan B for the formation of the corpus luteum. Many workers however doubt the existence of the two factors, and in any case it is safe to say that the separation has not been established by unequivocal experiments.

The main function of the prolan is therefore to initiate the maturation of the follicle followed by ovulation and the formation of corpus luteum. When the ovary is passing through these changes it also produces its own internal secretion, œstrin, which passes from the ovary to the uterus and the vagina, and produces the characteristic changes of œstrus.

Actions of Œstrin

It was not until an accurate method of testing for this hormone was devised that research on the chemical nature of œstrin could be undertaken. The test consists in studying the effects of injections of œstrin upon castrated rats or mice.

In these rodents the changes accompanying the reproductive cycle are characterised by a certain cell-picture in the vaginal contents. It is usual to classify the periods in the œstrus cycle as di-œstrus, pro-œstrus, œstrus, and meta-œstrus. If a vaginal smear be made of an animal in the di-œstrus or resting stage, and it be stained in some suitable manner, it will be noticed that the field will be crowded with leucocytes. The animal is incapable of impregnation and it is in this condition that the castrated or ovariectomised animal remains for all time.

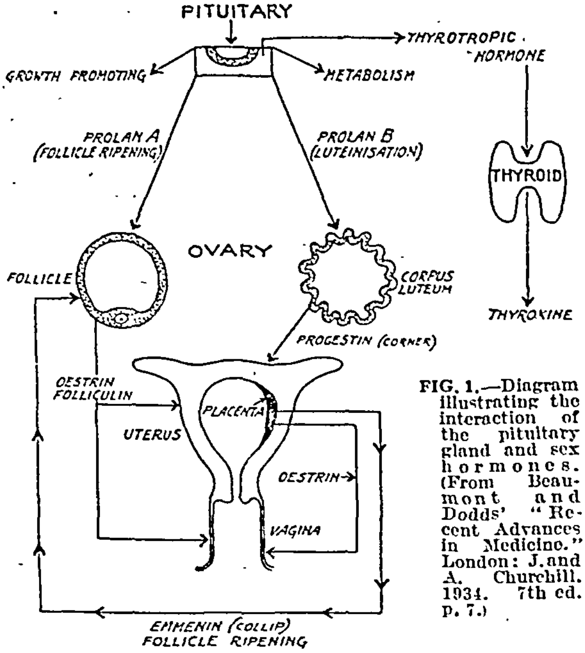

FIG. 1.—Diagram illustrating the interaction of the pituitary gland and sex hormones. (From Beaumont and Dodds' "Recent Advances in Medicine." London: J. and A. Churchill. 1934. 7th ed. p. 7.)

After five days or so the di-œstrus period gives way to a period of pro-œstrus, in which it is found that the leucocytes have disappeared from the field and a number of nucleated epithelial cells have appeared. At this stage the animal is incapable of receiving the male, but in a few hours this period changes to one of full œstrus when it can be seen that the field is occupied by non-nucleated cornified cells. The appearance is characteristic even to the naked eye and cannot be mistaken by the experienced observer.

At this stage the animal receives the male and is capable of becoming impregnated. If this does not occur, nucleated epithelial cells begin to appear again, and leucocytes characterising the stage of meta-œstrus; and finally di-œstrus is reached. There are various other changes which occur in the body at the height of œstrus. The uterus enlarges and the cavity becomes distended with fluid. All these changes occur as the result of œstrin secreted presumably by the ovaries. If the ovaries are removed the animal remains in a permanent state of di-œstrus, and it has been found possible to use such animals for investigating the activity of ovarian extracts.

The first successful experiments on these lines were performed by Allen and Doisy (1923). These observers were able to show that an alcoholic extract of ovaries was capable of inducing all the stages of œstrus in castrated animals, thus obtaining absolute evidence of the activity of a stable extract. From this time onwards rapid advances were made in the chemistry of the compound. The distribution was rapidly worked out, and the substance was found to be present in the ovaries and follicular fluid; it was also found in large quantities in the mammalian placenta. Unfortunately alcohol and volatile solvents will extract from body tissues a complex group of substances all with very similar properties, and consequently very little progress was made in the determination of the exact chemical constitution of the œstrus-producing hormone. It was, however, quickly proved to contain only carbon, hydrogen, and oxygen, but its separation from inert contaminants proved an all but impossible task.

Another great step was made through the discovery by Aschheim and Zondek (1927) that the œstrus-producing hormone was excreted in the urine in mammalian pregnancy, and moreover, in this situation it is not contaminated with the mass of substances that are found in alcoholic extracts of tissues.

At the same time Aschheim and Zondek also noticed the presence of prolan in the urine, and upon this discovery is based their well-known reaction for pregnancy. Œstrin may appear in conditions other than pregnancy, but apart from hydatidiform mole, the presence of prolan in the urine in any quantity is a specific sign of pregnancy.

A simple benzene extract of the urine was found to yield large quantities of the œstrus-producing hormone in a state of purity which has hitherto been deemed almost impossible, even with the most elaborate purification. Groups of investigators throughout the world commenced to study chemical properties, and in a relatively short time the hormone was obtained *in crystalline form*. Doisy and his collaborators in America (Doisy, Veler and Thayer, 1929 and 1930) and Butenandt in Germany (1929), independently and almost simultaneously, announced the crystallisation of the substance. At a later date Marrian (1930) and Laqueur and his co-workers (1929, 1930) also obtained crystalline products.

Chemical Relationships of Œstrin

It must be remembered that up to this date no one had any idea as to what group of organic compound œstrin belonged. The properties would fit in with a number of well-known groups, and the only remarkable features concerning the crystals were, first their extreme potency—namely, some 10,000,000 international units per gramme—and secondly their stability towards organic reagents and alkalis. I do not propose to trace the various steps leading to the adoption of the formula now believed in, since this would take too long and would prove tedious except to pure organic chemists. A number of workers have taken part in this important research, and amongst their names are to be found those of Doisy, Butenandt, and Marrian (see general references). We believe to-day that œstrin has the following formulæ (Fig. 2):—

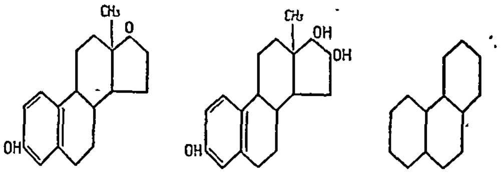

FIG. 2.—Ketohydroxy œstrin. Trihydroxy œstrin. Phenanthrene.

It belongs to a group known as condensed carbon ring compounds and consists of a series of three six-membered rings fused together with a five-membered ring at one end of the molecule. It is a derivative of phenanthrene which is shown here, and until comparatively recently it was not known that this group of bodies occurred in the animal organisation. The phenanthrene molecule has been known for many years to be possessed by certain drugs such as morphine, which, however, has quite a different molecule.

The condensed carbon ring system is now known to be of very great importance among the organic compounds occurring in the body. These include cholesterol and its derivatives the bile acids, ergosterol and calciferol, and the male and female sex hormones. One can state, therefore, that the organic chemist has provided the physiologist, biochemist, and physician with an entirely new problem in metabolism—namely, that of the sterols or condensed carbon ring compounds. The formula shown in Fig. 3 indicates the relatively close relationship of the important members of this group.

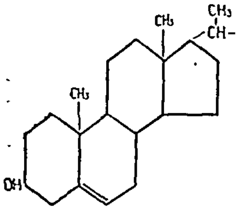

FIG. 3.—Cholesterol.

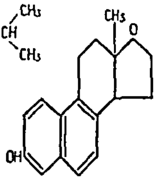

FIG. 4. Equilenine.

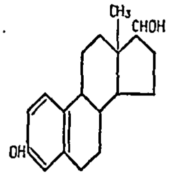

FIG. 5. Dihydrofolliculin.

In general it may be stated that the active members consist of a phenanthrene molecule with a five-membered ring attached to one end of the molecule, and that various polar groups, side chains, double bonds, &c., are possibly associated with the different types of activity of the different molecules. One of the most interesting observations in connexion with the œstrus-producing hormone arose through a consideration of its molecular structure. The first compound isolated in the crystalline form by Doisy had the formula $C_{18}H_{22}O_2$ and it has proved on subsequent investigation by Butenandt and others to be ketohydroxy-œstrin of the formula already given. On the other hand, the substance isolated by Marrian (1930) has been proved by them to have the empirical formula $C_{18}H_{24}O_3$. It therefore contains one more molecule of water than the ketohydroxy-œstrin.

It is very interesting to note that both ketohydroxy-œstrin and trihydroxy-œstrin are capable of producing œstrus in animals, but that the latter is much less active than the former. Here is an example of a hormone that may have slight differences of molecular construction and still retain its activity.

Marrian also succeeded in isolating another interesting compound that is quite inactive in the doses in which it has been tested up to the present. It is an alcohol which is known as pregnandiol (Marrian, 1929).

Girard (1933) has isolated a series of interesting compounds from the urine of the pregnant mare, one of which he terms equilenine. The formula of equilenine is shown in Fig. 4, and it can be seen that it differs remarkably from the formula of the œstrus-producing hormone, in that two of the rings are aromatic.

Yet further interesting experiments may be performed by modifying the construction of the molecule. Thus it may be shown that if the follicular hormone be partially hydrogenated and two atoms of hydrogen be added, the compound known as dihydrofolliculin is produced (formula shown in Fig. 5). In this case the activity increases from 10,000,000 to 40,000,000 units per gramme, and the compound becomes infinitely more active when administered by mouth. If further hydrogenation be undertaken and the aromatic ring be completely hydrogenated with the addition of another six atoms of hydrogen, the compound loses its power of producing œstrus, but develops the properties of the male sex hormone —namely, that it will cause comb growth in the capon and enlargement of the seminal vesicles. Moreover, trihydroxy-œstrin may be converted to ketohydroxy-œstrin by vacuum distillation over potassium bi-sulphate.

We can see, therefore, that starting from a substance manufactured by the body, it is possible to effect minor changes in the molecular construction which increase and decrease the œstrogenic power, and it is even possible to produce compounds capable of taking the place of the male sex hormone.

Girard has illustrated the relationship between the bile acids and the compounds that we have just discussed, in the manner shown in Fig. 6.

It must be remembered that up to the present the starting material has been the naturally occurring substance, ketohydroxy-œstrin. Attempts to synthesise compounds of this type are fraught with the very greatest difficulty, since in addition to the complication of the individual preparations, the question of stereo-isomerism enters.

Clinical Use of Œstrin

It might perhaps occur to the pure clinician to inquire what is the practical outcome of all this organic chemistry. Fortunately it is very easy to answer this question.

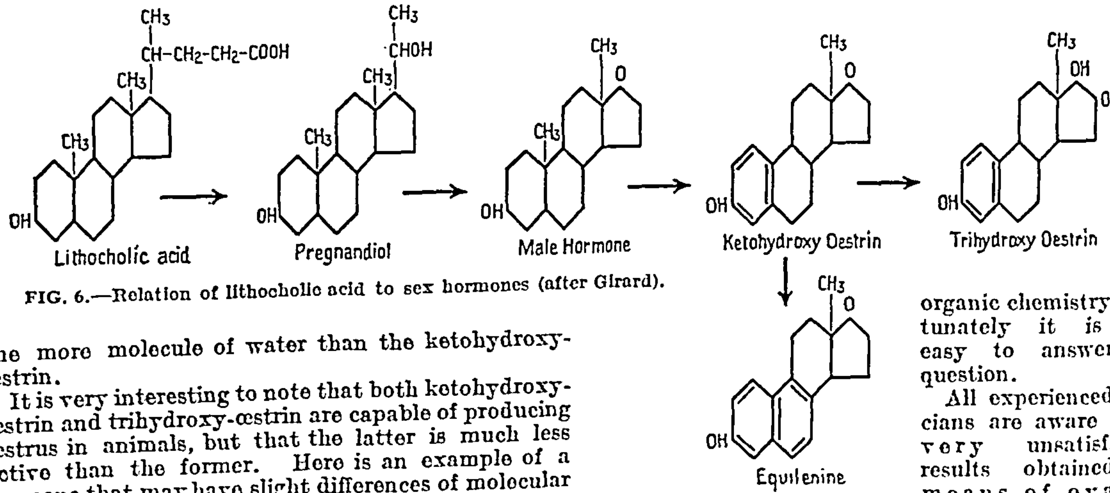

FIG. 6.—Relation of lithocholic acid to sex hormones (after Girard).

All experienced clinicians are aware of the very unsatisfactory results obtained by means of ovarian therapy, and it is safe to say that most gynæcologists of experience regard all methods of substitution therapy as valueless. The reason for this is quite apparent if a moment's consideration be given.

If we take the mouse unit as the unit of œstrin, we know that one mouse unit will produce œstrus in a mouse. Marrian and Parkes (1930) have shown that it is necessary to give some 200 to 300 units in order to produce the full œstrus together with uterine changes; in other words, some 300 units must be administered before the full physiological results can be obtained and the animal will accept the male. Parkes and I were able to show that provided the same method be employed, the rat unit is ten times the mouse unit—in other words, in direct proportion to the body-weight. Therefore 3000 units would have to be given to a rat to produce the full physiological change. Parkes and Zuckerman (1931) have shown that the ovariectomised baboon requires a quantity of œstrin in direct proportion to its body-weight, and arguing on these lines it is obvious that a woman would require some 500,000 international units of œstrin to produce a physiological effect.

At a meeting of the Royal Society of Medicine some time ago these figures were mentioned and were treated with derision, since it was argued that under no circumstances would it be possible to produce a sufficient quantity of material for the treatment of even a few cases, and in any case the expense would be prohibitive. At a meeting of the same society on Feb. 13th, 1934, C. Kaufmann described his experiments with women who had undergone the operation of complete ovariectomy but with the uterus still intact. He described how he was able to produce complete menstruation by the administration of some 500,000 to 1,000,000 units of œstrin together with a small quantity of the corpus luteum hormone. I have also been able to repeat these observations and to check the result by curettage. Kaufmann (1934) proved conclusively that it is possible to produce a complete menstrual period in an ovariectomised woman, and also to cause enlargement of the uterus in cases of infantilism; and at the same time to treat menopausal symptoms with huge doses of the œstrin.

These remarkable investigations would not have been possible but for the elaborate and painstaking chemical work that I have described. The study of the methods of separation which resulted in a very good commercial yield of ketohydroxy-œstrin, and the brilliant discovery of Schwenk and Hildebrandt in Schoeller's laboratory (1933) that the partially hydrogenated product enabled the yield to be quadrupled, has made it possible to produce œstrin in sufficient quantities for this entirely new branch of therapeutics to be opened up.

INTERNATIONAL COÖPERATION IN PUBLIC HEALTH

ITS ACHIEVEMENTS AND PROSPECTS [*]

BY SIR GEORGE S. BUCHANAN, C.B., M.D., F.R.C.P. Lond.

LECTURE II

Cancer Studies

PERSONALLY I have always opposed proposals that the League's Health Organisation should enter on the road of conferences on cancer at large; we are not strong enough to do them well, nor do I believe that much good would come of them from the official point of view. But still, cancer is among the greatest of the causes of mortality, and all Government health services, sooner or later, must occupy themselves with cancer questions. At Geneva we have selected two lines: first the comparison of national cancer statistics, which occupied us from 1923–27; and later, the results of radiological treatment of cancer of the uterus. For both there were special reasons.

Comparative Studies.—A Cancer Commission of the Health Committee, of which I had the honour of being President, was appointed in 1923 and reappointed in 1926. Up to 1927 the principal work of this Commission consisted in making serious endeavours to ascertain the different causes which produced the very notable difference in the mortality from cancer in certain, mainly European, countries. The countries in question all possessed national mortality statistics for a long series of past years, and there was no prima facie reason to consider any one of them to be more favourably placed than the others in regard to accurate diagnosis of cancer as a cause of morbidity or mortality. The sites chosen for study were the breast and uterus, organs for which on the one hand diagnosis of the cause of death is relatively easy, and on the other hand the mortality differences between the countries was most striking.

The inquiry was pursued by expert statistical analysis of massed figures and also by special sampling investigations organised by the Commission, and numerous useful monographs on different aspects of the question were obtained. When the inquiry was rounded off, in October, 1927, by the summarising report (C.H. 631), there were both failures and successes to record: failures, in that every conceivable method of analysis open to the Commission and its distinguished experts had failed to produce any single clear-cut explanation of the divergencies in the national mortalities from cancer in the countries studied; successes, in that many plausible a priori explanations had been thoroughly tested and found wanting. The ground was cleared of all kinds of misconceptions about the effect of registration systems, age-distribution, marital state, racial proclivity, and the like —work which wanted doing, and could only have been secured by the special international expert methods of inquiry which were followed. And a further and not inconsiderable practical benefit resulted; the so-called "natural" duration of cancer in these sites was determined on a broad basis of observation, while the predominating importance of early diagnosis and early operative (or radiological) treatment was illustrated equally for every country: useful public action for the prevention of cancer of these sites, in present knowledge, consists almost wholly in facilitating this early diagnosis and treatment. Among the British participants in this work grateful mention must be made of Prof. Major Greenwood and Dr. Janet Lane-Claypon.

---

[*] The Milroy Lectures delivered before the Royal College of Physicians of London on Feb. 27th and March 1st, 1934, with a few subsequent additions of detail. Lecture III. will appear in a coming issue.

The Health Committee, in 1928, following the advice of the Cancer Commission itself, decided to regard these comparative inquiries as completed. Their resumption after a few years, perhaps with some new methods of approach, may well prove desirable.

RADIOLOGICAL TREATMENT

The work of the sub-commission appointed on this subject is summarised in a report of June, 1929 (League publication C.H. 788), which—in English-speaking countries at least—has received much attention and been recognised as authoritative. This report set out some very necessary general principles in regard to the use of radiotherapy in general. In addition, the way in which radiotherapy was applied to cancer of the uterus at Paris, Munich, and Stockholm was explained; and the necessity for standardising observations and records, including facts as to recurrence of the growth and length of survival after treatment, was demonstrated.

It emerged from this inquiry that while governments, and hospitals, and philanthropists are spending enormous sums on the purchase of radium and in the provision of other radiological treatment, no satisfactory way of assessing or comparing results of different radiotherapeutic methods can be found unless the principal radium and gynæcological institutes will agree to adopt (1) a standard nomenclature to describe the stages of the disease; (2) an agreed method of case-recording; and (3) a satisfactory system of following up treated cases to ascertain their condition at least three years after treatment.

The recommendations of the Radiology sub-commission, endorsed by the Cancer Commission and the Health Committee, were quite explicit and authoritative on these three requirements. It was then necessary to promote their observance, and in due course to collect the results and submit them to competent expert analysis. For this purpose recourse was had to administrations, institutes, and individuals in a considerable number of countries, which were provided with special case-record books in different languages. It was necessary, moreover, to explain the method which it was desired to follow in some detail, and so far as possible to arrange that some one person in each country would be charged with the distribution of the records and would periodically report on their use. For the United Kingdom this duty has been undertaken by my colleague, Colonel Smallman, and some 30 of our more important hospitals and institutes have for over two years kept particular records of radiologically treated cases of cancer of the uterus on the international form, in addition, in many cases, to the maintenance of other records of the same cases for the purposes of our own Radium Commission. The lines on which an ultimate analysis of these records will be made are to be settled by a conference of gynæcologists and radiologists to be held this year in Zurich, at the same time as the International Radiological Congress. It is impossible to forecast the results, but it seems equally impossible to believe that the examination of data obtained on these uniform lines by so many responsible authorities will not supply a definite and useful addition to knowledge of the subject which would be unobtainable in any other way, and which will itself justify the trouble which has been taken in recording cases and in following them up from year to year to ascertain their after-histories.

I have dealt rather at length with the expert commissions and inquiries undertaken from Geneva into essentially medical subjects as it is a part of the work which is perhaps not as well understood as it deserves to be, and yet at the same time appears to me to offer great advantage to medicine if it is used judiciously and with discrimination and always with the intention that its quality should be such that the professional man and technician will associate good solid work with a League Commission on the subjects he knows about. It is only in this way that the meetings of the "experts"—you must pardon the inevitable Geneva term because of its convenience—can be made more than occasions for an agreeable interchange of platitudes and a search for convenient formulæ to hide divergence of opinion and enable each participant to go on his own way as before. All who take part in these joint inquiries should feel that they have an unusual opportunity which may not recur to gain from pooling knowledge and collectively to advance it. The function of the Health Organisation is the modest but essential one of providing the opportunity; and of seeing that, when appropriate cases arise, medicine obtains the advantages which an experienced international organisation, with its headquarter mechanism, translators, précis writers, and funds can supply with greater ease than another. Given care and thought in the selection of what is appropriate from the side of medical needs I see no reason for any check in the progress which has thus far been made; on the contrary, there is every reason to hope for its extension as its quality becomes better known and more impulses for its continuance come from the medical side in different countries.

General Work of the Health Organisation of the League of Nations

My references to the other directions in which the League of Nations has occupied itself with public health work must be brief; many of them are better known than the essentially medical activities I have just been speaking of. There is a most important service of the League for *industrial medicine*. My reference to it must be brief, since the Conventions and Agreements relating to industrial hygiene, as well as its journal "Occupational Hygiene," are not dealth with by the Health Organisation, with which I personally am familiar, but by a separate medical section of the staff of the International Labour Office, deriving authority from the general duties placed upon that Office in the Covenant.

SERVICE OF INDUSTRIAL MEDICINE OF THE INTERNATIONAL LABOUR OFFICE

This service has an expert staff, budget, and procedure, all under the direction of the International Labour Office, which, though an organ of the League of Nations, has its own constitution and independent international obligations. On the health side, in the United Kingdom, this work naturally comes to the medical branch of the Factory Department of the Home Office. The service was created within the International Labour Office on the recommendation of the Hygiene Commission appointed by the Washington Conference in 1919, and it is charged with the study of health conditions amongst all classes of workers, and with the maintenance of close and constant contact with the government medical departments concerned with the administration of labour legislation. Its principal duties fall into two categories:—

1. The preparation of subjects for consideration by the International Labour Conference, with a view to the adoption of *Draft Conventions and Recommendations* which are eventually submitted to the competent national authority in each country for ratification or other action.

2. The collection and dissemination of information on all matters relating to industrial health, which are likely to be of international interest.

Some 32 international conventions have been concluded to date through the International Labour Office, and have been ratified to a larger or smaller extent by States non-members as well as by States members of the League. Of these, those which have resulted specially from the work of the service of industrial medicine relate to White Lead (1921) and Compensation for Occupational Diseases (1925); while the Governing Body of the I.L.O. is also responsible for other conventions specially concerned with occupational hygiene, such as those on Childbirth (1919), and on the Medical Examination of Young Persons at Sea (1921). Besides effecting these international agreements the Governing Body has in many cases submitted detailed recommendations to Governments on action to be taken in health questions affecting the worker; for example, Anthrax, White Phosphorus (1919), Lead poisoning, Maternity in Agriculture (1921), and general principles of sickness insurance (1927).

The service, under its Director, Dr. L. Carozzi, has organised technical studies on the above and other subjects by means of special expert committees—e.g., for anthrax, lead poisoning, and silicosis—or by means of its Correspondence Committee; the results coming for action to the Governing Body of the I.L.O.

The service has also collaborated with various national bodies in the study of industrial fatigue, the occurrence of tar and pitch cancer and cancer due to mineral oils, and of colour vision tests for railwaymen and seamen. It maintains a continuous review of industrial medical questions which is published by I.L.O. under the name of "Occupation and Health," with a corresponding issue in French. The service at present is giving special attention to the protection of married women in industry, to the pathology and hygiene of workers handling solvents of acetyl and nitro-cellulose, as well as silicosis, on which a special study, greatly aided by Dr. Irvine of Johannesburg, has been made since 1925, with notable practical results.

INTERNATIONAL REGULATION OF OPIUM AND DRUGS OF ADDICTION

I should mention also, but again without attempting to develop the subject, that the Health Organisation of the League, in conjunction with the Paris Office, fulfils certain technical duties in connexion with the organisation at Geneva for the control of opium and other drugs of addiction. The health organisations here have no concern with administrative policy, but they advise when cases are put before them in regard to particular drugs to which the provisions of the Opium Convention, 1925, should apply as being drugs of addiction, or for which exemptions should be allowed. This work, as may be supposed, is confided by both Offices to an expert Commission.

THE HEALTH MISSIONS OF THE LEAGUE

Public health questions have proved a very useful means by which the League of Nations has been able to make its influence felt in different parts of the world, particularly in extra-European countries which have no very strong urge to participate in the many of the political branches of the League's work. Looking down the list of missions, collective or individual, which have been arranged from Geneva, one notes visits for one or other public health purpose to Persia, to the Islands of the Pacific, to Bolivia and Liberia, and to a considerable group of Latin-American countries, in addition to the special attention which has been given to Eastern Europe—e.g., Czechoslovakia, Yugoslavia, and Greece. To this must be added a quite special attention to health conditions in the Far East, which began with Dr. Norman White's mission to Far Eastern countries, particularly on quarantine questions, in February, 1924, and which in recent years have been conducted on a very considerable scale, mainly under Dr. Rajchman's own direction, in China. It is difficult to generalise about these missions. Their objects have been very different, and the choice of personnel, collective or individual, has, of course, depended on the purpose in view. In all cases, however, they have constituted a response from the League to a request from the country or countries concerned for consultation or advice on some administrative question or on some particular matter of disease prevalence. They have resulted at the time in instructive reports, and not seldom the recommendations made in these reports have been the starting point of definite administrative changes, or the foundation of a new school of hygiene, the reorganisation of hospital services, and like matters. The mission has served the purpose of an activator.

These missions have sometimes been conducted by medical officers of suitable nationalities whom the League has borrowed, sometimes by members of the salaried staff of the Health Section at Geneva, and sometimes by a combination of both. They form an excellent example of the principle that countries' members of the League should help each other as far as possible. If rightly carried out, these missions can be so arranged and conducted as to avoid any impression or intention that it is the business of the League's Health Organisation to be in any way executive, or to constitute itself a super-health authority which supervises or criticises the public health administrations of the world. It is particularly important, in my view, that no such impression should be created. Countries have a complete right, subject to the observation of any international agreements to which they are parties, to care for the health of their people in their own way, as their traditions or their policies lead them. I doubt if the world would gain by having stock patterns of administration pressed upon nations by any central authority; I feel sure it would not benefit by stock patterns of national administration in medicine or hygiene. Any recommendations on administrative matters which come from the League must always be considered from this point of view. If, for example, advice were given to all countries in the world which assumed that medicine and public health ought, for choice, to be effected through an all-embracing State insurance system, or ought all to be worked by central authority, it would not help us in the United Kingdom to have such advice thrust on us exotically, even if we favoured the principles. And as we could not favour the principles, we should only weaken the League and waste valuable time, by having to be continually on our defence against them.

Reverting to League missions it is worth noting, in passing, that where the medical side has been only one of the aspects of the mission, the medical representative has sometimes proved so valuable that the League has afterwards used his services for wider purposes. Dr. M. D. Mackenzie's visit to Liberia—e.g., in October, 1931—was followed by his being designated by the League in the following year to be one of the Commissioners appointed to delimit frontiers and settle intertribal disputes in that country. Similarly, on a larger scale, the energy with which Dr. Rajchman threw himself into the creation and organisation of health services in China under the Nationalist Government has led to his now being seconded from the post of Medical Director to that of the chief representative of the League in China in respect of all technical questions—economics, communications, opium control, &c., as well as health, on which it has been decided to maintain a special liaison between the Chinese National Government and the League. As the expenses of these missions may be considerable, it should be noted that they do not necessarily fall on our health budget; in the case of Latin-America and China they fall on special funds voted by the Assembly.

In connexion with the funds of the Health Organisation, it is well also to note that the normal budget does not allow us at Geneva to undertake work for the suppression of epidemics or give medical services in the case of catastrophes such as floods and earthquakes out of our own funds. Something has from time to time been done in these directions under special funds, notably in the early days of the League. In general, however, any assistance which has been possible to particular nations in times of epidemics has been limited to local visits and advice and not extended to the employment of staffs or the provision of hospital or other material.

INTERCHANGES AND INTELLIGENCE WORK

At an early stage donations from the Rockefeller Foundation enabled the Medical Director to inaugurate a method of mutual instruction in public health administration to be evolved by what is known as the "interchange" system. Two methods are followed under this system. In the first a public health officer, or in some cases a man appointed to a public health post which he has not yet taken up, is given special facilities for visiting selected countries for the purpose of study. This is little more than an extension of what is done, on a larger scale, by the Rockefeller Foundation itself. In the second, "collective" interchanges are arranged—that is to say, a group of medical officers of different countries is brought together for a number of weeks during which it visits a selected country for study of its principal health problems and public health methods. In a few cases also these "collective" interchanges have been specialised to particular subjects—for example, milk control or rural hygiene. The "interchange" system is a distinctive feature in the Geneva work. Not the least advantage of the "collective" interchanges has been that the health authorities of the country visited take pains in advance to consider the questions which their foreign visitors are most likely to ask, and the information which should be prepared for them, so that the visit has produced a number of valuable monographs describing the main lines of medical and public health activities. This has been done, for example, for France, Germany, Switzerland, and Denmark, and, last year, excellently for Poland. Naturally the number of participants from any given country is small but we have secured the benefit for several central or local health officers in the United Kingdom. In the case of visitors to this country, either collectively or individually, we were fortunate at the beginning to secure the assistance of the Society of Medical Officers of Health, while later, the London School of Hygiene and Tropical Medicine undertook to provide an organised centre from which the tours and interviews of foreign visitors are arranged. I may venture here to testify to the smoothness and efficiency with which this work is undertaken at the School and the obligation which the organisers of these interchanges are under to Medical Officers of Health, Directors of Institutes and other bodies for the time and labour which they are frequently asked to sacrifice in giving necessary explanations and demonstrations to our foreign visitors.

Besides using this interchange system to collect and publish information regarding the practice of public health administration in different countries, the medical staff at Geneva sometimes achieves the same object by making visits themselves or arranging for them to be made by others. Some of these inquiries have been concerned with particular aspects of public health work—e.g., rural hygiene or the control over tuberculosis and leprosy; an inquiry into certain aspects of public hospital provision in the United Kingdom is now in progress. Mention should be made here of the series of Statistical Handbooks (for 14 countries, done under the advice of Prof. Major Greenwood) issued as League publications between 1924 and 1928. Their object was to supply for each country an account of the way in which its system of obtaining and classifying mortality statistics has been evolved, and what particular considerations relating to that country must be kept in mind by the student who is using its national death-rates.

Of course, when it comes to obtaining information about the main lines and policy of public health work and medical practice in another country, much care has to be taken by the foreign observer to get the essential points of the picture and set the national practices in their proper relation to the method of government and characteristics of the country concerned. It is by no means easy for the stranger to avoid giving disproportionate emphasis to particular matters which have struck him as novel or unusual. He may create unexpected difficulties by his criticisms, or at the other extreme his reports or observations may be embarrassing to the national administration by the praise which he has given to what those who know consider unsatisfactory. That these difficulties are not insurmountable, especially when the observer is in a position of complete freedom in his reports, has lately been shown by the series of international studies conducted for the Milbank Memorial Fund by Sir Arthur Newsholme and his collaborators, and has been shown also in the reports of experts who have reported for the Health Section of the League. At the present time there is particular value in some of these reports on medical developments abroad. Under the new dictatorships and oligarchies of European countries, entirely new methods of health administration and arrangements for the care of the sick are being introduced and imposed from above, sometimes with all the impulse of a freeing of national spirit and with all the force of modern propaganda. If in the United Kingdom we do things differently for the reason that medical and public health progress is not with us a new thing, but has gone on through generations as part of the normal requirements of our central and local government, it does not follow that our slower evolution has always led us to the points which the countries now starting from scratch are endeavouring to attain by a single jump. Our own progress may not be leading us in the directions being aimed at—for example, in Poland or in the U.S.S.R.—but it is certainly advisable to realise what the aims and objects of such countries are. In Poland, for instance, during the last few years they have created a huge new system of preventive medicine by means of local health centres under State direction throughout the country, and at the same time have developed their system of health insurance to the extent that 80 per cent. of the population receives treatment under the insurance agencies which is not merely domiciliary, as with us, but includes hospital beds and all kinds of specialist services. In the U.S.S.R. all treatment and prevention of disease are recognised as being from first to last an affair for the State to provide, while it is regarded as legitimate to use the medical services and the results achieved by them as a political weapon in the hands of the Government—for example, as a weapon in the official war against religion. We can, and should, keep our own national lines, but we cannot afford to ignore the results which are being rapidly obtained under these new systems; we should know the facts and learn the lessons they can teach us.

FAR EASTERN HEALTH BUREAU AT SINGAPORE

Sketchy as it necessarily is, my reference to the work of the Health Organisation of the League would be too incomplete without some words about its Far Eastern Bureau at Singapore. The medical secretariat at Geneva has at Singapore a kind of branch office. Its first Director was Dr. Gilbert Brooke, and after him for some years Dr. Gautier, who now directs the publications at the Geneva Office. The office is now filled by Dr. C. L. Park, a senior officer in the Australian Commonwealth Public Health Service, who also brought to it a large experience of the League of Nations' work. The idea that the League would do some special work in health for the Far East presented itself to us quite early; we owe it, in fact, largely to the Japanese delegate, Dr. Miyajima, and to the example set by Japan, which gave special subsidies and facilities for the purpose. Its actual establishment followed a notable tour by Dr. Norman White to the Far East in 1922–23. At that time, so far as international official agreements about infectious disease were concerned, we were still under the system of intercommunication through diplomatic channels, and Dr. White showed that in this part of the world these agreements for the mutual communication of information meant little in practice. He also showed us that the measures taken in regard to the formidable infectious diseases, notably cholera and plague, were being conducted by the countries and colonies on individualistic and arbitrary lines which were difficult to defend. Whatever might ultimately be done in the way of reforming quarantine procedure in the Far East, one thing seemed immediately practicable and desirable—namely, to arrange that the public health authorities of different countries in that region had a good system of exchanging information about the existence of infection in their ports. The first object of the Far Eastern Bureau therefore was to be the centre through which, with the minimum of formalities, the different countries could pool their information about epidemics. Evidently a great deal of use could be made of wireless messages, and we were satisfied that, whether for wireless or for cables, a code should be feasible which would enable essential facts to be sent through quickly and economically. The Bureau at Singapore was set up with the financial assistance not only of some of the Far Eastern Governments but also, and very substantially, with the aid of the Rockefeller Foundation. It was organised on the advice of and after several conferences with representatives of various Far Eastern medical services, notably those of India, the Dutch East Indies, Japan, and the United States for the Philippines, and it was provided with an Advisory Committee on which the services of Major-General J. D. Graham, late Public Health Commissioner with the Government of India, were invaluable, and over which he presided for several years. On the advice of this Committee also the Bureau has occupied itself with other matters of interest in disease prevention in these regions, notably with coördination of researches into epidemic diseases.

The Bureau was a going concern and had fully justified the intentions of its founders by 1926, when the International Sanitary Conference of Paris, to which I will presently refer, was held, and the whole question of organising the transmission of news regarding infectious diseases at ports was placed on a new basis. The basis then adopted, in fact, was one which the Singapore Bureau had already shown to be practicable. One of the clauses in the 1926 Convention enabled the work of the Bureau to be utilised in the world scheme which has since been put into operation. It has continued and extended the work for which it was founded, and has been of substantial value by providing an outpost from the Geneva office working for a large section of the world which can only have a limited contact with Europe.

I may add here, though it has no connexion with the League of Nations, that there is another international bureau which obtains information about infectious diseases over as wide a region. This is the Pan-American Sanitary Bureau at Washington, whose intelligence system, greatly aided by the United States public health service, covers the two Americas. Like the Singapore Bureau for the Far East, it is now linked up in the common world system of information about epidemics established internationally in 1926.

THE PAN-AMERICAN SANITARY CONFERENCES, BUREAU, AND SANITARY CODE

The creation of the Pan-American Sanitary Conferences and of the Pan-American Sanitary Bureau was authorised by resolutions adopted by the Second International Conference of the American States, which met in Mexico City, Oct. 22nd, 1901–Jan. 22nd, 1902. These Conferences and the Bureau were originally known as "International" instead of "Pan-American," the names having been changed because of the creation of the Office International d'Hygiène publique of Paris.

The Pan-American Sanitary Bureau, which is the executive organ of the Pan-American Sanitary Conferences, was actually formed or organised by the First International Sanitary Conference of American Republics, which met in Washington, Dec. 2nd, 3rd, and 4th, 1902. Each succeeding Sanitary Conference, of which there have been seven, has elected (or re-elected) the officers of the Bureau, consisting of an Honorary Director, the Director, the Vice-Director, a Secretary, and four members. Employees are appointed by the Director.

The status of the Pan-American Sanitary Bureau is definitely fixed by the Pan-American Sanitary Code (Chapter IX., page 13), an international sanitary treaty which revised (and in part reiterated) the Washington Convention of 1905. This code or treaty was signed by the Seventh Pan-American Sanitary Conference at Havana, Cuba, on Nov. 14th, 1924. It has been ratified by 19 American Republics to date, and its provisions are adhered to by the Health Authorities of the other two.

This code was prepared for inter-American practice, and was based in large measure on the International Sanitary Conventions. It has not been superseded by the International Sanitary Convention of 1926, to which it is regarded as forming a complementary though independent document.

The Bureau, since the Directorship of Surgeon-General Cumming in 1920, has sent technical officers to different American States for special services; it publishes an official bulletin besides providing the intelligence system above referred to.

To avoid a confusion which sometimes arises, it should be added that the Fifth International Conference of American Republics (not a Sanitary Conference) authorised the Director of the Pan-American Sanitary Bureau to call together in Washington, once in five years, the Directing Heads of the Departments of Health of the 21 American Republics. This body is separate and distinct from the Pan-American Sanitary Conferences and on a different basis. Whereas delegates to the Pan-American Sanitary Conferences have plenary powers within certain limitations and can actually make *ad referendum* treaties, the meetings of the Directors of Health have no such powers

Office International d'Hygiène Publique

It will have been realised that when dealing with the League of Nations health work one has been concerned with expert consultations, missions, intelligence work and the like which essentially are dependent on and arranged by the Medical or Health Section of the League Secretariat, and to a considerable extent carried out by its own medical staff. This Health Section has the aid of a Health Committee of the League, appointed by the Council triennially, which advises on principles, receives reports (often after their publication), and forwards them to the Council. Meetings of this Committee are regulated accordingly and are not now held very frequently. At the Office International d'Hygiène publique in Paris the position of its Permanent Committee is quite a different one. The greater part of the work of that Office is based on regular half-yearly sessions of the Committee itself and on the communications which the Government delegates who form the Committee make themselves, or bring from the experts they have consulted in their own countries. The half-yearly sessions of the Paris Committee are busy ones, extending over ten days. The Governments now represented by delegates are as many as 51—in the case of the British Empire including separate delegates for the several Dominions and India and for the British Colonies. The United States and Russia—now the U.S.S.R.—have been represented from the beginning, while such important countries as Japan and Germany, Rumania and Czechoslovakia have become members of the Office within the last ten years, and have strengthened it greatly by bringing in the work of their public health services. The funds of the Paris Office are derived exclusively from the participating Governments, on a system fixed in 1907. The annual total is materially less than that of the annual health budget of the League.

To appreciate what it is that keeps the Paris Committee busy and justifies the attendance of representatives of Government health services from all parts of the world, it is useful to glance back at the circumstances which led to the establishment of the Office International and its Permanent Committee by the International Agreement of Rome, 1907, under which it works. The roots will be found in the great epidemic visitations of plague and cholera in the earlier part of the last century. It is enough to turn to any contemporary accounts of these epidemics in the Levant—read for example the description of plague in Cairo in "Eothen"—and consider how these periodical scourges used to be feared by Mediterranean countries and in Europe generally, to appreciate the way in which every country had come independently to protect itself and its frontiers by the methods then thought to be possible and effective. It was the period of the erection of large lazarets for the detention of persons arriving from suspected places, if indeed they were not arbitrarily detained for days or weeks in harbour on the ships which brought them or were, quite inhumanly, refused admission and sent away to any other country. It was a time also when merchandise was rejected wholesale or destroyed on suspicion of infection, each country acting in these respects on its own lines and in its own lights. The situation in regard to plague and yellow fever had by 1851 become so troublesome and the inconveniences to commerce so great, particularly in the Levant and the Mediterranean basin, that an effort was made by a few countries by means of a conference in Paris in that year to obtain some mutual understandings about the requirements which they would make in the case of shipping in the Mediterranean basin. The countries sending delegates were Austria, Spain, France, Great Britain, Greece, and Sardinia, the British representative being Dr. Sutherland, at that time in the service of the Privy Council. There followed the war years of the Crimea as well as the cholera visitations of 1853 and 1854, increasing the confusion and leading to other conferences—at Paris in 1859, at Constantinople in 1866, and at Vienna in 1874. At these conferences the necessity of a common understanding made some progress, evident again at later conferences in Washington in 1881 and at Rome in 1885. But it was not until 1892 at Venice that a formal "sanitary convention"[1] between countries made its appearance. This was the result of a general desire to control the introduction of *cholera* into the Mediterranean basin from the East by the Suez Canal route. A conference in the following year at Dresden extended the mutual agreements on this subject, while in 1894 another international conference at Paris settled mutual arrangements for the sanitary regulation of the Pilgrimage to Mecca and questions of quarantine in the Persian Gulf. Then in 1896 came the revival of *plague* in Bombay and its rapid extension to various parts of the world. The plague position was taken up by an international conference in Venice in 1897, and following the appearance of plague in Egypt in 1899, the various conventions by this time established were again considered at the sanitary conference at Paris in 1903, which for the first time prepared an international convention which dealt both with cholera and with plague.

An important factor of these conferences and conventions, which essentially were concerned with the protection of Europe from eastern infection, was the fact that a large section of the Levantine ports were controlled by a quasi-international body at Constantinople—namely, the Constantinople Superior Board of Health. The history of this body, which dated from 1838, has been admirably recorded by Dr. Clemow.[2]

CONSTANTINOPLE SUPERIOR BOARD OF HEALTH, 1838–1914

As an administrative body in the old Turkish Empire, dependent in large measure on the foreign consulates at Constantinople, the Superior Board of Health passed through several changes and stormy periods during the 75 years of its existence. It became, however, an important organisation, which maintained a sanitary service (1) at all the chief ports of the Black Sea, in the Straits, and on the coast of Asia Minor; (2) in the Red Sea and for the Mecca Pilgrimage; and (3) on the Turko-Persian frontier and for the Shiah pilgrimage. It had a very large staff, chiefly of Levantine medical officers, and quite large funds; quarantine dues were high in the Near East during last century, and still remain so. Its functions came to an end at the outbreak of the war in 1914, and its formal winding up, the distribution of its property, and the compensation to its personnel were provided for by the Treaty of Lausanne, 1923, and completed in 1927.

---

[1] In series, the General "International Sanitary Conventions" have been those of Venice, 1892; Paris, 1903; Paris, 1912; and Paris, 1926. The term "sanitary" dates back to the wider use of the word, as used for example by Simon in "English Sanitary Institutions."

[2] See THE LANCET, 1923, i., 1074, 1120, and 1180, and 1929, i., 93.

The action taken by the Constantinople Board was in large measure determined and regulated by the successive International Sanitary Conventions, and the same was the case with another quasi-international body, the Quarantine Board of Egypt, established about the same period. The latter has continued its existence and since the war has increased its importance in the scheme of protection against the transmission of epidemic diseases from the East.

LE CONSEIL SANITAIRE MARITIME ET QUARANTENAIRE D'EGYPTE

This body, usually known as the Egyptian Quarantine Board, has its headquarters in Alexandria. Financially, it depends, in major part, on the quarantine dues obtained for its services and in part also on the Government of Egypt. Its main functions are the protection of Egypt from invasion by infectious diseases on its frontiers, particularly its seaports, and the protection of the countries in the Mediterranean and beyond by means of the control which it exercises over the transit of vessels arriving from the south and passing through the Suez Canal. In addition, the Quarantine Board has various special health responsibilities in regard to the Mecca pilgrimage and pilgrim ships. The executive work is directed by the President of the Board, an appointment which now for a long period has been held by distinguished and capable administrators: Sir M. Amand Ruffer (1897–1917), Dr. Alexander Granville (1917–1923), the late Major C. F. Thomson (1925–1928), and its present occupant, Major J. Gilmour. The Board itself, on which for many years the British representative was Dr. A. Morrison, consists of representatives of the consular services of certain powers, whose position in the organisation has been determined by events in the history of Egypt which are political rather than medical. Authority formerly given to it by Khedivial decrees has been recognised internationally in successive International Sanitary Conventions, to which the quarantine regulations which it applies are expected to conform. The Convention of 1926 added some new duties to the Board, notably that of making an annual report on the general sanitary control of the Mecca pilgrimage and of forming a "regional bureau" of the Office International d'Hygiène publique in respect of intelligence about epidemics in countries in the Near East.

It is interesting to note, from evidence kindly given to me by Dr. Shahin Pacha, the present Minister of Health in Egypt, how far back this Board can trace its origins. It is a common assumption that the Board is a body originally imposed on the Government of Egypt by the European powers. In fact, however, it was a reverse process, as its beginnings are found as long ago as 1831, when Mahommed Ali called on the European Consular body in Alexandria to organise and apply measures against plague and other infectious diseases comparable to those then in vogue (and of appalling severity) in other ports of the Mediterranean; a request repeated and fortified in 1835, when the whole of the foreign consular body in that city were asked to undertake the direction of the service. As in those days, and long after until the opening of the Suez Canal in 1869, the ships to be quarantined were those arriving on the north from Mediterranean and Levantine ports, it is easy to understand how Alexandria was then, and has remained, the centre of all the Board's activities.

It is interesting to note the importance which in the middle of last century must have been attached in this country to the various conferences and conventions above mentioned, perhaps more from the commercial than from the public health point of view. It is true that we had had formidable invasions of Asiatic cholera in England, as no one is likely to forget in reading the English history of the century down to 1865. It was cholera almost as much as any other factor which determined the first establishment of a Government health service in the form of the Medical Department of the Privy Council. But that department, during the time of Simon's dogmatism and long afterwards, refused to place any serious reliance on attempts to prevent the importation of cholera. They considered periodical invasions of Europe (including England) by pandemic cholera to be inevitable. They desired, indeed, nothing to be done to diminish the lively apprehensions of cholera which were then doing so much good by bringing about the purification of our public water-supplies and by improving our internal measures of sanitation. The local sanitary authorities of our port towns were, of course, expected to protect themselves against the spread of cholera if it arrived, and had powers and duties to undertake inspection of ships within reasonable limits. But the work was essentially local. There was never at that time any question of Government subsidy or anything beyond the minimum of Government action at our ports. It was the time of great development of commerce on free trade principles, and the spirit of that time was all in favour of a British policy of freedom, which in many ways rightly prevailed, but sometimes went much further than other countries were disposed to accept, or even than we should be justified in maintaining now. This earlier policy was, of course, favoured by the limitations of epidemiological knowledge—the part played in infection by human, animal, or insect carriers was not realised, and there was little help from the laboratory.

New knowledge began to tell however, and in fact it was the repeated demonstration of the need for continued studies of the transmission of these pestilential diseases which led to the formation of the Office International d'Hygiène publique in Paris. Only by continuous expert study, and by recommendations agreed between the technical representatives of all the countries concerned, could the principles of the measures which should be taken and the obligations which Governments should jointly assume be fixed with any prospect of practical success. The proposal to establish an International Office for the purpose was made by that distinguished French diplomatist, happily still with us, M. Camille Barrère, as president of the Paris Conference of 1903. It took shape in 1907 in the agreement then made in Rome between 13 countries. The Bureau of the Office was established in Paris at 195, Boulevard St. Germain, and began its work in 1909, when the system of half-yearly meetings of the delegates was begun and has been followed from that beginning.

I will refer a little later to other work done by the Office, but to continue with the so-called pestilential diseases and quarantine questions, one may say here that the establishment of the Office at once justified itself when it became necessary again to revise the International Sanitary Convention in 1912, principally on account of the new situation created by the pushing forward of the Hedjaz railway, and the prospect at that time that the elaborate international system for preventing the recurrence of the spread of cholera by pilgrims returning from Mecca would have to be radically changed in consequence of this much-favoured Turkish project coming into operation. I note here in parentheses that this line has never been completed in Arabia, and it does not *at present constitute a practical factor in the sanitary* control of the Pilgrimage.

INTERNATIONAL CONTROL OVER THE ANNUAL PILGRIMAGE TO MECCA

Most of the conferences and conventions and a number of regional agreements have been concerned with the potential centre of distribution of cholera which is created when pilgrims from all parts of the Mohammedan world congregate during the days of the Haj at the several holy places of Arabia, and infection can readily be spread through their fouled and scanty water-supplies and otherwise. The range of the pilgrimage is surprising; it is made from Turkestan and the Caspian, from Northern and Western Africa, as well as from the nearby countries of the Levant. They meet there pilgrims from areas which are or have been endemic centres of cholera; many thousands from India, from Malaya, the Dutch East Indies, and even further afield. Some though not all of the classic cholera pandemics have thus had their origin. Between 1831 and 1912, as many as 27 years have been recorded in which epidemic cholera in connexion with the pilgrimage occurred on a larger or smaller scale. The notable English cholera epidemics of 1865–66 represented an extension from infection at Mecca in the first of these years[3]; the most formidable extension of cholera by the pilgrimage occurred in 1893.

After the interruption of the war years the pilgrimage reverted to its former size, and exceeded 100,000 in 1927. Since then, however, various causes, chiefly economic, have greatly reduced the annual figures, but the reduction may well be temporary. In any event the international arrangements to check the spread of infection must be maintained and made to respond to modern possibilities. The different phases of the elaborate international coöperation for this purpose are excellently set out by Dr. Duguet, Inspector-General of the Quarantine Board of Egypt, in his recent volume, "La Pélerinage de la Mecque" (Riever, Paris, 1932). Here it will suffice to note that the present system comprises: (*a*) provision for inspection of pilgrims before departure, and their vaccination against cholera; (*b*) detailed sanitary regulations applying to all pilgrim ships; (*c*) for ships coming to the Red Sea from the south, inspection at Kamaran, an island with a well-equipped sanitary station, now maintained by agreement (1926) between the Governments of British India and the Dutch East Indies; (*d*) for pilgrims coming by land routes sanitary passports and intercommunication between the authorities concerned, so as to regulate and minimise the repetition of medical measures taken at successive frontiers; (*e*) for pilgrims returning northward, examination at the quarantine station at El Tor, on the Sinai peninsula.

Considering the number of different nations and authorities which are concerned, the present system works surprisingly well and is achieving its main purpose. Since the International Sanitary Convention of 1926 it has come under annual survey by the Paris Office and its standing Pilgrimage Commission.

A MENTAL RECOVERY-RATE.—Dr. F. G. Jones, medical superintendent of the North Wales Mental Hospital at Denbigh, in his annual report states that the average recovery-rate among patients for the last 20 years was over 40 per cent., as compared with a mean rate throughout the mental hospitals in England and Wales of about 32 per cent. The death-rate was 4·2 per cent. on the average number resident—the lowest rate on record.

THE THERAPEUTIC ACTION OF PROSTIGMIN[*]

BY E. ARNOLD CARMICHAEL, M.B. Edin.,
F.R.C.P. Lond.
LATE CHIEF ASSISTANT IN THE MEDICAL PROFESSORIAL UNIT, ST. BARTHOLOMEW'S HOSPITAL, LONDON

F. R. FRASER, M.D. Edin., F.R.C.P. Lond.
DIRECTOR OF THE UNIT; PROFESSOR OF MEDICINE IN THE UNIVERSITY OF LONDON

D. MCKELVEY, M.C., M.D. Edin., F.R.C.S. Eng.
MAJOR, R.A.M.C.; SURGICAL SPECIALIST AT THE ROYAL HERBERT HOSPITAL, WOOLWICH; AND

D. P. D. WILKIE, M.D. Edin., F.R.C.S. Eng.
PROFESSOR OF SURGERY IN THE UNIVERSITY OF EDINBURGH

IN 1931 Aeschlimann and Reinert[1] published a report on the pharmacological action of some analogues of physostigmine and showed that the dimethylcarbamic ester of 3-oxyphenyl-trimethyl-ammonium-methyl sulphate is as active as physostigmine in stimulating intestinal peristalsis, but that its effect on the heart and circulation is less. This substance is known as Prostigmin and is recommended for therapeutic use as an intestinal stimulant when given by subcutaneous, intramuscular, or intravenous injection, especially in cases of post-operative intestinal atony. Following favourable reports on its therapeutic value by Weigand,[2] Leiner,[3] and Tourneux, Petel, and Gouzi,[4] and a study of its action on the intestinal tract by means of X ray examinations by Kottlors,[5] many accounts of the beneficial effect of this substance in intestinal atony have been published, but so far no reports on its value have appeared in this country.

The action of prostigmin has been observed in 41 patients. It was administered by subcutaneous or intramuscular injection of the solution provided in ampoules by the manufacturers. Thirteen of the patients were selected from among ordinary hospital in-patients not because the action claimed by the manufacturers was desired, but because they presented no special lesion of the digestive tract that would interfere with observations on the action of the drug under approximately normal conditions. In 28 instances patients were selected because the action claimed was desired, and in 16 of these post-operative intestinal distension was present.

EFFECT UPON HEART-RATE AND BLOOD PRESSURE

In view of the close similarity in chemical constitution of prostigmin and physostigmine, observations on heart-rate and blood pressure were made for some minutes before and for 30 to 60 minutes following the subcutaneous injection of prostigmin in 10 patients. The doses used were:—

1 c.cm. = 0·0005 g.* in 2 cases.
2 ,, = 0·001 g. ,, 7 ,,
3 ,, = 0·0015 g. ,, 1 case.
and in one a second injection of 4 c.cm. = 0·002 g.

* This is the dose recommended.

In none of them was any significant change in heart-rate or blood pressure observed with doses of 1, 2, or 3 c.cm., nor was any discomfort produced other than that referable to an action on the digestive tract. As a rule, both heart-rate and blood pressure showed a slight but steady reduction during the periods of observation, but following 4 c.cm (0·002 g.), which was given on one occasion only, an average pulse-rate of 116 before injection was reduced to 84 half an hour after the injection, a greater fall than can easily be accounted for as the result of the loss of nervousness and anticipation. One patient showed slight sweating, and two others some twitching of the muscles of the limbs and trunk, but in none of these instances was discomfort produced, and it was not possible to say that these phenomena were the result of the prostigmin. Slight transient local discomfort was produced by the subcutaneous injection of the solution.

---

[*] A Report to the Therapeutic Trials Committee of the Medical Research Council. The prostigmin used in these tests was manufactured by F. Hoffmann-La Roche and Co., A.-G., Basle, and submitted to the Committee by the Hoffmann-La Roche Chemical Works, Ltd., London.

EFFECTS REFERABLE TO ACTION ON DIGESTIVE TRACT

In all of the 13 patients, without any interference with intestinal action, a sensation of excessive activity and movement was experienced in the abdomen, variously described as "rumbling," "wind," "gurgling," "griping pains." This usually commenced in 10 to 20 minutes after the injection and lasted for a varying period of time from one or two minutes up to an hour. When well marked it increased for some minutes and was at a maximum 30 to 40 minutes after the injection and then gradually lessened in intensity. Most of the patients passed some wind by the rectum and two asked for the bed-pan, one at 15 minutes and one at 30 minutes after the injection, but did not defæcate and the desire to do so rapidly passed off. In three instances nausea was experienced following 2 c.cm. (0·001 g.), and vomiting occurred following the dose of 4 c.cm. (0·002 g.).

Three patients selected because of difficulty with the action of the bowels, but not post-operative distension, require more detailed consideration.

(*a*) A man, aged 20, with acute rheumatism and pericarditis, had had no action of the bowels for two days. He did not experience any sensations following the injection of 2 c.cm. (0·001 g.). A soap-and-water enema was given 3½ hours after the injection, and he had a large and satisfactory motion.

(*b*) A man, aged 65, with cerebral thrombosis and a right-sided hemiplegia, had much difficulty in opening his bowels. For two weeks he had no satisfactory result in spite of repeated enemata. Twenty-five minutes after the injection of 2 c.cm. (0·001 g.) he asked for the bed-pan and continued to use it for three-quarters of an hour, a very good evacuation resulting, but accompanied by severe griping pains, and he was much exhausted.

(*c*) A man, aged 28, suffering from incontinence of fæces following a crush fracture of the spine, had had no movement of the bowels for 21 hours. Thirty-five minutes after the injection of 2 c.cm. (0·001 g.) and following much rumbling in the abdomen he emptied his bowels in the bed. A further injection of 4 c.cm. (0·002 g.) was given a few days later; 28 minutes afterwards he had an involuntary evacuation of the bowels and a little later he vomited.

In an endeavour to determine more clearly the action of the drug causing the sensations of increased movement of the intestines recorded above but seldom resulting in an emptying of the bowels, (*a*) two patients with colostomy were observed, and (*b*) four patients were examined by X rays following barium meals.

(*a*) (1) Colostomy was performed on a man, aged 56, for inoperable carcinoma of the rectum, the opening being at the junction of the descending and sigmoid portions of the colon, and 11 days later he was given an injection of 2 c.cm. (0·001 g.). The sensations of abdominal unrest commenced in six minutes and increased for three-quarters of an hour, after which they gradually subsided. At times they amounted to pain. Small quantities of wind were passed at frequent intervals by the colostomy opening but no liquid or solid contents, and the exposed portion of the colon was seen to contract and relax from time to time, these movements coinciding with the passage of wind.

(2) A woman, aged 39, was suffering from acute obstruction due to megacolon and volvulus and a resection of the sigmoid colon was performed, with the formation of an artificial anus at the lower end of the descending colon. Fifteen days later she was given an injection of 2 c.cm. (0·001 g.). The sensations of abdominal activity commenced 13 minutes later and increased somewhat in intensity for a quarter of an hour and were still noticeable at the end of three-quarters of an hour. During this time small quantities of wind only were passed by the colostomy opening. The abdominal wall was very thin and patterns were observed as of contractions and distensions in the ascending and transverse colon, and the exposed portion of the colon was seen to contract and relax from time to time. At one time, about 30 minutes after the injection, a movement was seen through the abdominal wall as if a wave of contraction passed along the colon from the cæcum to the splenic flexure.

These observations were made two hours before the patients were due to have the daily washing-out of their colons, and when this was done fæcal material was returned as usual in both cases. It is of interest, therefore, that in spite of the manifest activity of movement in the colon wind only was passed.

(*b*) Three patients were given a barium meal six hours previously so that the colon was filled, and a second meal immediately before the injection of prostigmin; a fourth had the first meal only, as the stomach still contained enough at the end of six hours to enable the condition of the stomach to be observed. The patients were examined from time to time with the fluoroscopic screen during at least an hour following the injection. In two of the patients who received 1 c.cm. (0·0005 g.) no movements that could be regarded as abnormal were seen, although both had sensations of abdominal activity to a slight extent. The other two received 2 c.cm. (0·001 g.). In one of them at the end of three-quarters of an hour alternate contractions and relaxations were seen in the descending colon and continued for a quarter of an hour, a type of movement that is not usually observed in the colon during X ray examinations in subjects with normal intestinal tracts. The second patient showed similar movements in the transverse and descending colon for 10 minutes at the end of three-quarters of an hour after the injection, and one short wave of contraction was observed to pass along the transverse and descending colon. This type of movement also is not commonly seen in normal intestinal tracts.

In all four of these subjects active movements of the stomach and small intestine, consisting of contractions and relaxations and peristaltic waves, were observed, but it is not possible to say that they were abnormal.

POST-OPERATIVE CASES WITH DISTENSION

Prostigmin was given in 16 cases of abdominal distension following surgical operation.

CASE 1.—A man, aged 44, was operated on for carcinoma of the stomach and a partial gastrectomy performed. Three days after the operation signs of general peritonitis appeared with abdominal distension. On the following day the distension was increasing and no wind was passed. Fifteen minutes after the injection of 1 c.cm. (0·0005 g.) he asked for the bed-pan but without result, a turpentine enema was given but no wind or fæces were passed. A further injection of 1 c.cm. was given four hours later and a turpentine enema 20 minutes after it, and a little wind was passed. The patient died next day, and at autopsy general peritonitis was found.

CASE 2.—A woman, aged 74, was admitted suffering from acute intestinal obstruction, due to a carcinoma of the transverse colon. For this a cæcostomy was performed. The cæcostomy did not act well and the small intestine became greatly distended. Inserting a large tube into the cæcostomy produced little result. An injection of 1 c.cm. (0·0005 g.) produced within ten minutes a remarkable effect—very active movements were induced and several bowls were filled with fæcal content from the cæcostomy opening in the course of a few minutes. In this case a very effective small intestine propulsion was induced.

CASE 3.—A man aged 56. Investigation showed a scirrhous carcinoma of the stomach with secondary duodenal ileus from infiltration of the root of the mesentery. A duodeno-jejunostomy was performed. Three days later he was greatly trouble with flatulence which did not yield to flatus enemata. The injection of 1 c.cm. (0·0005 g.) produced almost immediately movements of the small intestine. He expressed the feeling that a movement commenced as high up as the stomach and passed progressively down the bowel. A small flatus enema now gave a very satisfactory result. The injection was repeated on a second occasion and the result was equally good.

CASE 4.—A woman, aged 50, suffered from carcinoma of the rectum. A preliminary colostomy was performed through the left rectus muscle. Owing to œdema and tight gripping of the muscle the colostomy did not act well. Even when a rubber tube was inserted little came away. The injection of 1 c.cm. (0·0005 g.) produced an immediate activity, and a further insertion of the tube resulted in an evacuation with relief. On a second occasion the result was similar.

CASE 5.—A man, aged 42, suffered from a gangrenous and perforated appendix with diffuse peritonitis. He developed abdominal distension with obstructive symptoms on the fifth day after operation. On three occasions he was given 1 c.cm. (0·0005 g.) followed by enemata, without satisfactory result. Jejunostomy was required, but a fatal result followed. In this case there was an organic obstruction from adhesions, and this explained the failure of prostigmin to produce an evacuation.

CASE 6.—A man, aged 40, had a gastro-jejunostomy performed for duodenal ulcer. He complained of flatulent distension on the second day. This was not relieved by a flatus enema. The injection of 1 c.cm. (0·0005 g.) produced activity, and an enema given ten minutes later produced a large and satisfactory passage of flatus. The patient asked to have the injection repeated on the following day, when the result was equally satisfactory.

CASE 7.—A man aged 21. Operation for chronic appendicitis with adhesions. Marked gaseous distension occurred on 3rd, 4th, and 5th days after operation. On two occasions 1 c.cm. (0·0005 g.) of prostigmin, followed by a small enema, produced the free passage of flatus. Later a third dose produced little result, and 1 c.cm. of pituitrin given two hours later was much more effective. On the following day prostigmin again produced little result, but pituitrin, given some hours later, was again effective. In this case prostigmin appeared to be less effective than pituitrin, but it is possible that the combination of the two drugs helped to produce the ultimately satisfactory result.

CASE 8.—A woman aged 66. Operated upon for chronic appendicitis with adhesions round the lower end of the ileum. The appendix was removed and the adhesions divided. On the second day after operation she became greatly distended and unable to pass flatus. An injection of 1 c.cm. (0·0005 g.) produced, within six minutes, considerable rumbling of gas with immediate relief, and an enema given some minutes later produced an excellent result. She was quite satisfied that after the injection and before the enema was given she got pronounced relief.

CASE 9.—A man, aged 32, was operated on for chronic appendicitis. Numerous adhesions had to be divided and considerable handling of the small intestine took place. On the evening of the second day following operation he complained bitterly of flatulent distension. A flatus enema gave slight relief, but his discomfort quickly returned. He was given 2 c.cm. (0·001 g.) of prostigmin. Twelve minutes later he had griping pains and much rumbling, but no passage of flatus. This continued for 15 minutes. He was then given a flatus enema with a very satisfactory result.

CASE 10.—A man aged 26. Marked abdominal distension and vomiting occurring three days after an operation for the relief of acute obstruction due to adhesions. 1 c.cm. (0·0005 g.), by intramuscular injection, followed by a 10 per cent. glycerin enema produced a satisfactory evacuation of flatus and fæces. On the following day some distension which occurred was again relieved by repetition of the treatment.

CASE 11.—A girl aged 7. Abdominal distension and vomiting occurred two days after operation for appendix abscess. An ordinary enema gave no relief. The injection of 0·5 c.cm. (0·00025 g.) intramuscularly, followed by a glycerin enema, produced no beneficial result. Four hours later 1 c.cm. (0·0005 g.) was given and followed by a glycerin enema. Following this a free action of the bowels took place and the patient gave no cause for further anxiety.

CASE 12.—A man aged 22. Marked abdominal distension and vomiting occurring three days after operation for gangrenous appendicitis with peritonitis. Intramuscular injection of 1 c.cm. (0·0005 g.), followed by a glycerin enema, failed to produce any beneficial result. This was repeated in four hours and again failed to produce any change in the condition, except some increase in the abdominal discomfort. A satisfactory evacuation resulted some hours later, and after the administration of acetylcholine.

CASE 13.—A youth aged 18. Acute abdominal discomfort with distension occurring two days after operation for appendix abscess with local peritonitis. Intramuscular injection of 1 c.cm. (0·0005 g.), followed by a glycerin enema, produced a satisfactory result in that the bowels acted well and the discomfort disappeared.

CASE 14.—A man aged 20. Mild distension and colicky abdominal pain on the day following operation for acute appendicitis. A good action of the bowels with disappearance of the symptoms followed the intramuscular injection of 1 c.cm. (0·0005 g.) and a glycerin enema.

CASE 15.—A man aged 21. Severe intestinal colic on the day following an operation for acute appendicitis with local peritonitis. Intramuscular injection of 1 c.cm. (0·0005 g.), followed by a glycerin enema, failed to give any relief. This was repeated four hours later and was followed by the passage of flatus and fæces with complete relief of the symptoms.

CASE 16.—A woman aged 34. Marked abdominal distension with vomiting and colicky abdominal pain three days after operation for acute appendicitis with peritonitis. Intramuscular injection of 1 c.cm. (0·0005 g.), followed by a glycerin enema, resulted in the passage of flatus and fæces. Owing to a recurrence of the symptoms this was repeated on the following day with a satisfactory result.

POST-OPERATIVE CASES WITHOUT DISTENSION

In nine cases prostigmin was given after operation not associated with distension. An injection (intramuscular) of 1 c.cm. (0·0005 g.), followed by a glycerin enema, was given to each of four men between the ages of 18 and 22 years, who were suffering from mild abdominal discomfort on the day following operation for acute appendicitis. In two a satisfactory evacuation of the bowels took place with relief from the discomfort. In the other two no action of the bowels was obtained, and the discomfort was slightly increased. A normal recovery occurred in each instance.

An injection (intramuscular) of 1 c.cm. (0·0005 g.), followed by a glycerin enema, was given to each of five men, between the ages of 18 and 43 years, on the day following operation for inguinal hernia. In three a satisfactory evacuation of the bowels occurred, but in the other two no action resulted until after an aperient was given on the following day.

Conclusions

1. The injection, subcutaneous or intramuscular, of prostigmin produces in normal subjects active movements (contractions and relaxations) in the colon, but there is no evidence that these movements are such as to produce the forward passage of the contents of the colon. Considerable variation was seen in the intensity of the response of different individuals.

2. Prostigmin appears to be free from side-actions on the heart-rate and blood pressure when given in doses at least double the recommended dose.

3. In cases of gaseous distension of the intestine, prostigmin is of value. In from 10 to 20 minutes following its injection abdominal pains and rumblings occur, and these go on for almost 30 minutes. It is necessary to give an enema to get a satisfactory passage of flatus.

4. It is suggested that prostigmin, followed by pituitrin, and then an enema, may be an effective measure for stimulating peristalsis in post-operative distension.

ACUTE PERFORATION OF PEPTIC ULCERS

By T. G. Illtyd James, M.Ch. Wales, F.R.C.S. Eng.
DEPUTY MEDICAL SUPERINTENDENT, THE CENTRAL MIDDLESEX COUNTY HOSPITAL, LONDON; AND

N. M. Matheson, F.R.C.S. Eng.
ASSISTANT MEDICAL OFFICER TO THE HOSPITAL

This survey presents some features of 75 cases of perforated gastric and duodenal ulcers operated on by us—with special reference to the incidence, the diagnosis, and the immediate complications. There were 63 males and 12 females. The distribution is shown in Table I.

Table I

—	—	Duodenal.	Gastric.		
			Pyloric.	Mid-gastric.	High gastric.
Males ..	63	48	6	5	4
Females ..	12	4	1	6	1

Although males outnumber females by more than five to one, the proportion of females is rather higher than usual. There is an overwhelming preponderance of duodenal perforations in the male, while in the female the perforation of gastric ulcer has been twice as frequent as that of duodenal ulcer.

In the gastric perforations the ulcer was found on the anterior surface of the stomach—at or close to the lesser curve—in all but one, where the perforation occurred into the lesser sac from an ulcer high up on the posterior aspect of the stomach near the cardiac orifice. In all the duodenal cases the perforation was found on the anterior surface of the first part.

AGE AND PREVIOUS HISTORY

Half of the perforations in this series occurred in the fifth and sixth decades, the fifth decade being found the commonest for both gastric and duodenal ulcers in both sexes. The oldest patient was a woman of 74, and the youngest a man of 19. Twelve patients had no previous symptoms, while in 11 indigestion had been present for a period under four weeks. In the remainder there was a history of digestive disturbance ranging from a few months to over twenty years. The proportion of patients with no previous symptoms is higher than that usually recorded. It is worthy of note that nearly all these cases were duodenal perforations, and the importance of bearing in mind this frequency is evident from the diagnostic point of view. Three patients gave a history of hæmatemesis twelve, nine, and four months respectively prior to perforation, while one patient returned twelve months later with a second perforation at the site of the original ulcer—having been free from symptoms in the interval. In five patients the onset of perforation was heralded by an exacerbation of digestive symptoms for several days before. This feature has been stressed by many observers, and especially by Moynihan.[1] It is strange, however, that this is not a more common event, for in nearly all cases the perforation is due to a progressive necrosis in the floor of a chronic ulcer. In all our cases perforation occurred at the site of a chronic ulcer, evidence of chronicity being found even when there was complete absence of previous digestive disturbance.

A search for any immediate cause of perforation led to no very definite conclusion. Some occurred during active work, others while the patient slept. The majority of our perforations occurred an hour or two after food. It is probable that some increase in gastric tension is the commonest precipitating factor; 11 of our cases followed a festive Christmas meal. In one the perforation of a duodenal ulcer appeared to be precipitated by a copious hæmatemesis—several bouts of vomiting being followed by the onset of acute pain and all the signs and symptoms of perforation.

TYPES OF PERFORATION

These were found to fall into three groups.

Group 1.—In the great majority the opening was of moderate size, round and punched out, about an eighth of an inch in diameter, through which duodenal or gastric contents had escaped in varying quantity. It is common experience that in duodenal perforations there is but little escape of gastric contents—probably from spasmodic closure of the pylorus.

Group 2.—The perforation was larger. The stomach was the common site of these bigger perforations, and the gross soiling of the peritoneum carried a correspondingly grave prognosis.

Group 3.—The opening was minute and partially or completely covered with lymph. Six cases fell into this group. They appear to be comparatively frequent, and usually occur when the stomach is empty and the small hole is rapidly covered by protective lymph. Moynihan[2] has long ago drawn attention to the importance of this group and the difficulties attaching to the diagnosis. The initial signs and symptoms of perforation rapidly abate and with suitable treatment complete healing may occur without operation. This occurred in one of our cases. In another a localised epigastric abscess developed. In a third case the barrier formed by the protective layer of lymph gave way after a period of 48 hours—with a return of the typical features—necessitating the usual operative measures.

---

[1] Practitioner, 1928, cxx., 138.
[2] Ann. Surg., 1907, xlv., 223.

Although perforation occurred most frequently after a meal, it was uncommon to find gross soiling of the peritoneum by food except in the gastric perforations. Multiple areas of fat necrosis in the omentum and subperitoneal fatty tissue were found in one case of duodenal ulcer—the perforation being near the junction of the first and second parts.

An attempt was made to estimate the acidity and peptic activity of the gastric juice obtained by means of a fine catheter inserted through the opening. The frequency of bile or food contamination, however, precluded any definite results being obtained.

DIAGNOSIS

The majority presented the characteristic features—sudden prostration by agonising abdominal pain, followed by tense immobility and a board-like tender abdomen. It is not proposed to elaborate all the details of such a well-known picture, but certain features are worthy of comment. A few patients presented a degree of activity that was surprising; one patient a hardy gipsy woman, with a perforation of one hour's duration, was able to walk a distance of one mile to hospital. Vomiting at the onset was present in about a third of our cases, but was not of any severity, while the pulse-rate was but little raised in the early stages except in elderly patients. Only five cases presented shoulder pain as a symptom. Absence of liver dullness was noted in 11 cases, two of these being of less than six hours' duration.

Difficulties in diagnosis do not usually arise in the majority of cases seen reasonably early, except in those falling into the third group. In these the initial general signs and symptoms quickly abate and become localised, simulating acute cholecystitis, acute appendicitis, or acute affections of the chest. The temperature is subnormal at the onset in nearly all perforations, thus affording a useful differential feature. Auscultation of the abdomen has been found of great value in the obscure case, for as a rule there was complete absence of peristaltic sounds, while in acute chest conditions they were never absent.

The demonstration of pneumoperitoneum is a diagnostic aid of very great value in a doubtful case. We have resorted to this method of diagnosis in one of our series where a small perforation of the duodenum covered with lymph was associated with chest signs which clouded the diagnostic picture. The skiagram—taken with a portable apparatus while the patient was in the Fowler position—revealed the typical sickle-shaped areas of free gas under the diaphragm, making the diagnosis obvious. The procedure can be carried out with little or no discomfort to the patient.

TREATMENT AND FATALITY

Simple closure, with reinforcement of the suture line by omentum, was performed in all cases with the exception of one where gastro-enterostomy was added. This was a case in which a perforation of the duodenum had recurred at the site of the original ulcer twelve months later. A right paramedian incision under general anæsthesia was employed in most cases, but where the general state of the patient was poor a median incision allowed a more rapid opening and closure of the abdomen. Spinal and local anæsthesia were found eminently satisfactory in suitable cases. Where the stomach contained food it was emptied by an œsophageal tube passed by the mouth during the operation. Strict abdominal toilet was employed only in gastric perforations where particles of food were found in the peritoneal cavity. Pelvic drainage was employed if the perforation had been in existence over twelve hours. The fatality was as follows:—

TABLE II

	Patients.	Deaths.	Fatality-rate per cent.
Duodenal ulcer ..	52	9	17
Gastric ulcer ..	23	9	39
Total	75	18	24

The higher fatality with perforated gastric ulcers is the experience of most surgeons. It is due, in all probability, to the greater soiling of the abdomen, especially if the opening is a large one, with a more rapidly oncoming peritonitis than that met with in perforations of the duodenum.

The fatal cases were found to fall into the following groups:—

1. Those dying within 48 hours of operation (5 cases). In these patients there was no improvement after the operation. They came to hospital late, with the general condition severely undermined; in one case advanced carcinoma of the cervix coexisted. In this group death was due to peritonitis.

2. Those dying between the third and the ninth day after operation (8 cases); following peritonitis (3); peritonitis and delirium tremens (1); broncho-pneumonia (2); broncho-pneumonia and parotitis (1); pulmonary embolism (1). As in the preceding group the main determining factors leading to a fatal issue were the time elapsing before treatment was instituted, the age of the patient, and the site of the perforation. The fatality rose to 100 per cent. in acute perforations of over 24 hours' duration. The death-rate rose with each decade, and the tendency of the elderly to succumb to pulmonary complications was illustrated by three deaths from broncho-pneumonia. Parotitis is now a rare complication, but may occur even when all precautions are taken.

3. Deaths occurring between 10 and 28 days (5 cases); following subphrenic abscess (1); residual pelvic abscess with intestinal obstruction (1); pneumonia (1); and hæmatemesis from an unsuspected ulcer (2).

Our cases illustrated that subphrenic and pelvic abscesses are the result of delay. Intestinal obstruction has been met with on two occasions and occurred around the site of the drainage-tube necessitated by gross peritoneal soiling.

The occurrence of hæmorrhage from a second ulcer led to a fatal termination in two cases, on the tenth and twenty-fourth post-operative day respectively. In each case the perforation had occurred in the duodenum, and the bleeding was shown at autopsy to have its origin in an unsuspected gastric ulcer—in one case eroding the splenic artery. The possibility of this occurrence indicates the desirability of searching for other ulcers at the time of operation and stresses the need for prolonged and thorough after-treatment.

It is often stated that bleeding ulcers do not perforate, and that perforating ulcers do not bleed, but we have seen this association in two cases. In one the perforation followed immediately upon a hæmatemesis, and in another profuse bleeding occurred from an ulcer high upon the lesser curve which had been sutured ten days before.

DIABETES MELLITUS IN CHILDREN

By Leslie Cole, M.D. Camb., F.R.C.P. Lond.

PHYSICIAN TO ADDENBROOKE'S HOSPITAL, CAMBRIDGE; UNIVERSITY TEACHER IN MEDICINE

This paper is based on observations on 18 patients with diabetes mellitus who attended Addenbrooke's Hospital between 1925 and 1933, and who at the time of onset were less than fifteen years old. In 5 the disease began before 1927, and until that year their treatment with insulin was intermittent and insufficient. All the 16 who survive have been under regular supervision from 1927 until the present time. The cases are unselected, and comprise all the diabetic children attending between 1927 and 1933.

Three of these children live in Cambridge and the remainder in the country or in villages and small towns between ten and fifty miles distant. As a rule it is impossible for them to attend hospital more often than once every two months for supervision. Many of them also live at considerable distances from their doctors, and in the event of complications developing treatment is often delayed. They are mostly drawn from an illiterate class, and although they themselves are usually of the more intelligent, it is difficult with the present organisation to teach them more than a few essential facts about the management of their disease.

CASE RECORDS

The following is a brief outline of the cases as reviewed up to October 1933. Under the heading of severity are given the results of a sugar-tolerance test with the fasting blood-sugar (per cent.) and the blood-sugar at half-hourly intervals after ingestion of a stated quantity of glucose. F.B.S. = fasting blood-sugar. C. = carbohydrate. P. = protein. F. = fat. (Hagedorn-Jensen mèthod throughout.)

Case 1.—*A girl now aged 15.* Chicken-pox at 4. When she was 7 years old (August 1925) her mother noticed that she was losing weight, was thirsty and passed much urine. Next month she was admitted to hospital, when the findings were: urine sugar, 5 per cent.; acetone and diacetic acid in large amounts; blood-sugar 0·24 per cent.; weight, 2 st. 12 lb. *Severity of disease* (November 1931). Sugar tolerance: F.B.S. (fasting blood-sugar) 0·28; (50 g. glucose) 0·36, 0·42, 0·46, 0·38; specimens of urine passed after one hour and three hours contained 22·8 g. glucose in all. *Present treatment.* Diet: total calories, 1884; calories per kg., 46; C. (carbohydrate) 150, P. (protein) 60, F. (fat) 110. Insulin: 25 units bis die. *Present condition.* Usual resting blood-sugar: 0·1. Usual urine findings: sugar-free. Weight: 6 st. 6 lb. Height: 5 ft. 1 in. Sexual development normal; no menstruation. Activity normal.

Case 2.—Male aged 21. In June 1925 he had mumps. There was no abdominal pain but it was followed by epigastric discomfort. A few weeks later thirst and polyuria developed, and in September sugar was discovered in the urine. He was then 12½ years old. *Severity and course of illness.* On admission to hospital (September 1925) large amounts of sugar and acetone bodies were present in the urine. Resting blood-sugar 0·28. Passed 113 g. of glucose on a restricted carbohydrate diet in 24 hours. Two days later was on the verge of coma. Weight: 4 st. 13 lb. For the first two years he was treated with a very low diet and insulin for a few weeks. During the next 18 months he had insulin, but not enough. The disease was then controlled and sufficient insulin given. Sugar-tolerance curve (January 1932): F.B.S., 0·28; (50 g. glucose) 0·40, 0·44, 0·43, 0·39, 0·39; urine specimens at the end of one hour and three hours contained 41·4 g. glucose. *Present treatment.* Diet: total calories, 1668; calories per kg., 25; C. 110, P. 70, F. 100. Insulin: 40 units b.d. *Present condition.* Usual resting blood-sugar: 0·10–0·18. Usual urine findings: sugar-free about every other visit. Weight: 11 st. 10 lb. Height: 5 ft. 11¾in. Sexual development normal. Activity normal; looks after a chicken farm and does a great deal of manual work.

Case 3.—Boy aged 14½. Always delicate and inclined to lose weight; mumps as a child. One brother died of diabetes at 25. In March 1932 he developed sudden thirst and polyuria and lost a lot of weight. After three days he was put on a small dose of insulin, about 100 units a week, given at irregular intervals. He remained weak, often too weak to get out of bed. *Severity.* Attended hospital for the first time in March 1933. Urine sp. gr., 1040; sugar and acetone bodies in large amounts; resting blood-sugar 0·27. Hypoglycæmic coma: one attack, with convulsions in August 1933: (had not taken breakfast). *Present treatment.* Diet: total calories, 1668; calories per kg., 41; C. 120, P. 60, F. 100. Insulin: 24 units b.d. *Present condition.* Resting blood-sugar, very variable and often high. Usually glycosuria. Weight: 6 st. 4 lb. Height: 4 ft. 10 in. Sexual development: penis infantile in type but just beginning to develop; only a few pubic hairs. Activity normal.

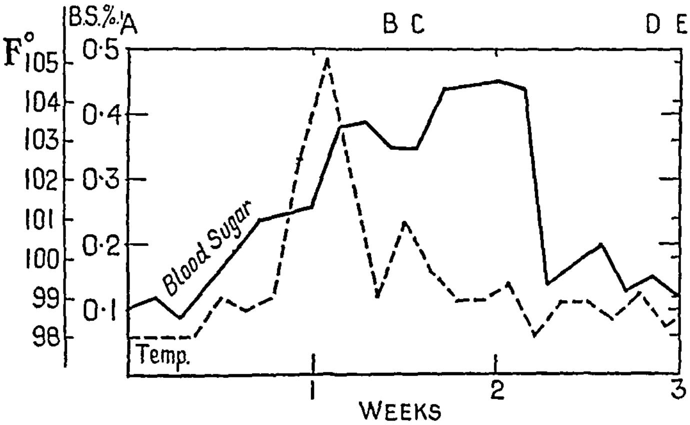
Case 4.—Boy aged 13½. Whooping-cough in 1921: vaccinated in 1925, *after which the arm did not heal* well and was bad for eight weeks. In December 1926 when he was 7 years old, he had "influenza," followed by mumps; this was a mild attack but there was some abdominal pain which lasted for over a week. Three weeks later he suddenly developed thirst, hunger, and polyuria and began to waste. (Weight in December 1926 4 st. 7 lb.) *Severity and course of illness.* On admission to hospital in March 1927 the urine (sp. gr. 1038) contained large amounts of sugar and acetone bodies. Resting blood-sugar 0·17; weight 3 st. 4 lb. The condition was only partially controlled by a very low diet and occasional insulin until March 1930, when weight was 4 st. 1½ lb. Adequate diet and sufficient insulin were then begun. Diabetic coma: March 1930 (insulin stopped); and August 1930 (empyema of maxillary antrum), although insulin 20 b.d. had been continued. Sugar-tolerance test (August 1931): F.B.S., 0·40; (50 g. glucose) 0·54, 0·56, 0·58, 0·56, 0·48. Specimens of urine at the end of one and three hours contained 36 g. glucose in all. *Present treatment.* Diet: total calories, 1550; calories per kg. 38; C. 80, P. 60, F. 105. Insulin: 25 units b.d. *Present condition.* Usual resting blood-sugar: 0·1; occasional relapses to 0·2. Usual urine findings: trace of sugar; occasional severe relapses. Weight: 6 st. 6 lb. Height: 4 ft. 8 in. Sexual development: penis still infantile; no pubic hair. Activity: Plays all games including football and swimming; top of his class and sings in college choir.

Case 5.—Girl aged 16¾. One brother died four years ago, aged 18. He was perfectly well until a few weeks before death; he then seemed out of sorts, and a few days of polyuria and thirst preceded coma. He was never admitted to hospital and received no insulin. The patient herself had a bad cold in July 1931 when she was 14¾ years old, and in the following month she developed wasting, lassitude and loss of weight, followed by thirst and polyuria of sudden onset. *Severity.* On admission to hospital in September 1931 the urine (sp. gr. 1040) contained sugar and acetone bodies in large amounts. Resting blood-sugar, 0·3. Weight 6 st. Mild attack of hypoglycæmic coma in November 1932. *Present treatment.* Diet: total calories, 1380; calories per kg., 26; C. 100, P. 55, F. 80. Insulin: 30 units b.d. *Present condition.* Usual resting blood-sugar: 0·1–0·3. Sugar always present in urine. Weight: 8 st. 6 lb. Height: 5 ft. 2 in. Sexual development: normal. The periods began in January 1931 and stopped at the onset of the diabetes: they were irregular in 1932 but regular in 1933. Activity normal.

Case 6.—Girl aged 17. Five years ago (October 1928); she suddenly complained of thirst and polyuria and began to lose weight. *Severity and course of illness.* In November 1928 the urine (sp. gr. 1038) contained much sugar and acetone, and the weight was 4 st. 12 lb. Septic

tonsils enucleated in November 1931, after diabetic coma (insulin stopped during infection). Sugar tolerance (April 1932): F.B.S., 0·4; (50 g. glucose) 0·48, 0·51, 0·51, 0·48; specimens passed after one and two hours contained 21 g. glucose. *Present treatment.* Diet: total calories, 1628; calories per kg., 28; C. 105, P. 54, F. 105. Insulin: 40 units b.d. *Present condition.* Usual resting blood-sugar: 0·15–0·25. Sugar present in urine as a rule. Weight: 9 st. 2 lb. Height: 5 ft. 1 in. Sexual development: normal, but no menstruation. Activity normal.

CASE 7.—Boy aged 10½. On Feb. 8th, 1933, he complained of thirst for a few weeks; he then scalded his foot and four days later was admitted to hospital on the verge of coma. *Severity.* On admission the blood-sugar was 0·38 and the urine contained much sugar and acetone bodies. Sugar tolerance: F.B.S., 0·23; (25 g. glucose) 0·22, 0·29, 0·33, 0·35, 0·23; urine passed one and three hours after glucose contained 16 g. glucose in all. *Present treatment.* Diet: total calories, 1810; calories per kg., 60; C. 200, P. 60, F. 80. Insulin: 10 units b.d. *Present condition.* Usual resting blood-sugar: 0·1. Urine usually contains a trace of sugar; relapses. Weight: 4 st. 11 lb. Height: 4 ft. 6½ in. Activity normal.



Case 13—Blood-sugar (per cent.) and temperature readings during an attack of bronchitis. A.–B., insulin 18 units b.d.; B.–C., 20 units b.d.; C.–D., 25 units b.d.; D.–E., 20 units b.d. Diet: diminution of usual diet during fever.

CASE 8.—Boy aged 9½. When he was 6 years old, in the summer of 1930, he developed thirst and polyuria, lost weight and became progressively more ill. In February 1931 he had an attack of "influenza" and in March sugar was found in urine. *Severity and course of illness.* On admission to hospital in March 1931 the urine contained sugar and acetone bodies; resting blood-sugar, 0·15. Sugar-tolerance curve: F.B.S., 0·15; (50 g. glucose) 0·18, 0·26, 0·31, 0·30, 0·25. Weight: 2 st. 9 lb. May 1931: hypoglycæmic coma; unconscious for three hours; sickness and convulsions. November 1931: convulsions and coma. *Present treatment.* Diet: total calories, 2060; calories per kg., 82; C. 160, P. 72, F. 120. Insulin: 11 units b.d. *Present condition.* Usual resting blood-sugar: 0·08–0·14. Urine usually sugar-free. Weight: 4 st. Height: 4 ft. 2 in. Activity normal.

CASE 9.—Girl aged 11. In January 1930, at age of 7½, she began to lose weight and did not seem fit. A few days later slight frequency developed and sugar was found in the urine. Ten units of insulin daily were given by her private doctor till she was admitted to hospital in the following April. *Severity and course of illness.* On admission the resting blood-sugar was 0·25 and the urine contained a large amount of sugar and acetone. Sugar tolerance (September 1931): F.B.S., 0·2; (50 g. glucose) 0·36, 0·47, 0·50, 0·51. Weight: 3 st. 3½ lb. In November 1931 she had hypoglycæmic coma; unconscious for four hours; no warning. In 1932 on two occasions she was unconscious for about two hours. A peculiar scream preceded these attacks. No treatment was given. *Present treatment.* Diet: total calories, 1640; calories per kg., 50; C. 102, P. 60, F. 105. Insulin: 20 units b.d. *Present condition.* Usual resting blood-sugar: 0·04–0·12. Usually sugar-free. Weight: 5 st. 3 lb. Height: 4 ft. 4½ in. Activity normal.

CASE 10.—Girl aged 18. Whooping-cough and chickenpox as an infant. One brother has diabetes and congenital heart disease (Case 11). When she was 11 years old (July 1926) she was noticed to be blinking her eyes in a curious way. Before this her eyesight had been good and she had won a prize at school. Thirst and polyuria came on a few weeks later, and sugar was found in urine. *Severity.* (January 1927). Blood-sugar, 0·2. Passing 35 g. of sugar on diet of 100 g. carbohydrate. Weight: 3 st. 11 lb. Sugar tolerance (August 1931): F.B.S., 0·27; (50 g. glucose) 0·36, 0·41, 0·44, 0·41, 0·36, 0·3; specimens at end of one, two, and three hours contained 33·8 g. glucose. *Treatment and course of illness.* January 1927: C. 22, P. 86, F. 157. Insulin: 8 units b.d. August 1929: C. 36, P. 86, F. 157; 10 units b.d. increasing to 14. August 1931: C. 85, P. 60, F. 120; 22 and 25 units b.d. April 1932: C. 130, P. 60, F. 100; 22 and 25 units b.d. *Vision* (1927): right eye 6/60, left 24/60; (1933) right eye 6/60, left 6/60. Cataract. *Present treatment.* Diet: total calories, 1709; calories per kg., 40; C. 130, P. 60, F. 100. Insulin: 23 and 25 b.d. *Present condition.* Usual resting blood-sugar: 0·05–0·13. Usually sugar-free. Weight: 6 st. 11 lb. Height: 5 ft. 2½ in. Sexual development normal; no menstruation. Cataracts have progressed slowly since onset and are now being treated surgically. Activity normal.

CASE 11.—Boy aged 15½. Always a "blue" child from birth and known to suffer from a congenital heart. One sister two years older has severe diabetes and cataract (Case 10). One aunt on father's side had diabetes. At age of 9 (May 1927) he lost weight and began to suffer from thirst and polyuria; his urine was then found to contain sugar. *Severity* (January 1928). Resting blood-sugar, 0·22. Sugar tolerance (August 1931): F.B.S., 0·2; (50 g. glucose) 0·36, 0·45, 0·49, 0·50, 0·43. Loud systolic murmur and thrill over præcordium; extreme cyanosis with gross clubbing of fingers and toes; right ventricular preponderance in electrocardiogram. Red cell count 9,800,000 per c.mm. Weight: 3 st. 2 lb. *Present treatment.* Diet: total calories, 1277; calories per kg., 44; C. 90, P. 40, F. 80. Insulin: 8 units b.d. *Present condition.* Usual resting blood-sugar, 0·18–0·2. Usual urine findings: sp. gr. 1010–12; rarely a faint trace of sugar. Weight: 4 st. 9 lb. Height: 4 ft. 6½ in. Activity: physical activity very limited because of heart; intelligent and fond of reading.

CASE 12.—Girl aged 7. One uncle died of pulmonary tuberculosis. In October 1929, at age of 3½, she began to pass water frequently and became pale and out of sorts. Her urine was then examined and found to contain sugar and acetone. *Severity.* On admission to hospital in November 1929 the urine (sp. gr. 1050) contained much sugar and acetone. The resting blood-sugar was 0·26, and the weight 1 st. 11 lb. She passed 22·8 g. glucose in 24 hours. Sugar tolerance (November 1931): F.B.S., 0·27; (40 g. glucose) 0·4, 0·46, 0·52, 0·58. Mild attack of hypoglycæmic coma in October 1931. *Present treatment.* Diet: total calories, 1813; calories per kg., 86; C. 110, P. 60, F. 120. Insulin: 12 units b.d. *Present condition.* Usual resting blood-sugar: 0·03–0·09. Usually sugar-free. Weight: 3 st. 5 lb. Height: 3 ft. 8 in. Activity normal.

CASE 13.—Diabetes came on when the patient, a girl, was 4 years old; she died at 5½. *Mode of onset.* In February 1931 she was off colour for several weeks. At the beginning of March she had a feverish cold and her doctor found sugar in the urine. On the following day she became drowsy and gradually comatose and was admitted to hospital in coma. *Severity and course of illness.* Urine: sp. gr. 1010; sugar and acetone in large amount. Blood-sugar 0·49. Comatose. Colon distended with fæces. Tonsils large and septic. Weight: 1 st. 13 lb. After recovery from coma and a period of treatment the tonsils were enucleated in April. Her blood-sugar readings were extremely unstable and glycosuria was very difficult to control even on 55 units of insulin daily given in three doses. In spite of this she remained very well. Discharged on C. 80, P. 34, F. 50, and 40 units insulin daily in two doses. On this the blood-sugar readings remained unstable and glycosuria was often considerable. She also had mild attacks of hypoglycæmia. In January 1932 she was readmitted. Her sugar tolerance was as follows: F.B.S., 0·37; (40 g. glucose) 0·39, 0·51, 0·57, 0·62, 0·57. She was given a larger diet with less insulin: C. 110, P. 60, F. 50; calories, 1162; calories per kg., 64; and 18 units b.d. Weight: 2 st. 12 lb. While an in-patient she contracted bronchitis which demonstrated how severe was her reaction to infection (see Figure). She was discharged in March 1932 and remained well with a more stable blood-sugar for a few months. In August she developed a cold and became drowsy. Her insulin was then stopped and she was finally admitted to hospital almost moribund.

CASE 14.—This patient was a boy who developed acute diabetes at the age of 13 and died. As a child he had had an operation for inguinal hernia. Five weeks before his death he contracted mumps. The attack was not severe and he did not complain of any abdominal symptoms. After the attack he did not seem very well. Three days before admission to hospital he suddenly became very thirsty, passed large quantities of urine, and could not sleep. On admission he was comatose and extremely dehydrated. He smelt strongly of acetone and his urine was full of sugar and acetone. Blood-sugar 0·65. He died ten hours later despite administration of 190 units of insulin, rectal and subcutaneous salines, and intravenous infusion.

CASE 15.—The patient, a girl, has had diabetes for about 7 years, and is now 21. She was admitted to hospital in February 1926, at the age of 13¼, with a three weeks' history of thirst and polyuria. *Severity and course of illness.* The blood-sugar on admission was 0·38. She was starved for three days and became sugar-free, remaining sugar-free on Graham's twelfth-day diet. The blood-sugar came down to 0·07. She was discharged on this diet. Weight: 7 st. No insulin given. She remained sugar-free on this diet until October 1928. There was then a return of thirst and polyuria, due probably to a dental abscess. Blood-sugar 0·3; weight: 7 st. 7 lb. She was readmitted, her teeth were treated and she was standardised on 10 units b.d. and seven lines (C. 35, P. 52, F. 105). She was again readmitted in May 1932 for restandardisation. Diet was increased to C. 115, P. 60, F. 120, with insulin 16 units b.d. Weight: 9 st. 6 lb. *Present treatment.* Diet: total calories, 1833; calories per kg., 30; C. 115, P. 60, F. 120. Insulin: 20 and 16 units. *Present condition.* Usual resting blood-sugar below 0·1; occasional higher readings. Usually sugar-free. Weight: 9 st. 8 lb. Height: 5 ft. 6½ in. Sexual development normal; no menstrual periods till May 1932; three since. Activity: lives a normal life at home; plays tennis. On the whole she has not felt quite so well since her diet was increased in 1932. She is introspective about her health and gets worried if she finds a trace of sugar in the urine.

CASE 16.—Boy aged 15. Scarlet fever at 5. Two cousins on father's side have diabetes; one, a boy of 19, since the age of 15 and the other, a girl of 16, since the age of 7; both take insulin. In January 1932, when he was 13¾, he complained of three weeks' thirst, hunger, and frequency of micturition with sudden onset; no wasting. *Severity and course of illness.* On admission (February 1932) he had sugar in urine but no acetone. Resting blood-sugar, 0·14. Sugar tolerance: F.B.S., 0·14: (50 g. glucose) 0·14, 0·18, 0·23, 0·24, 0·19: urine specimens at one hour and three hours contained 8·9 g. glucose in all. In March 1932 he was standardised on C. 150, P. 80, F. 120, and insulin 25 and 23 units daily. He remained well and sugar-free with a resting blood-sugar of 0·04–0·1 until December when he developed an acute maxillary antritis. Diet had subsequently to be reduced to present one. *Present treatment.* Diet: total calories, 1772; calories per kg., 36; C. 100, P. 60, F. 120. Insulin: 25 units b.d. *Present condition.* Usual resting blood-sugar: 0·04–0·16. Trace of sugar often present in urine. Weight: 7 st. 10 lb. Height: 5 ft. 2 in. Sexual development: penis infantile in type, and only beginning to develop; a few pubic hairs only. Activity normal.

CASE 17.—Boy aged 13½. History of occasional colds, measles, and chicken-pox. When he was twelve years old (April 1932) he had a sore-throat, and a fortnight after this he seemed to be passing more urine and eating and drinking a great deal. He seemed out of sorts and lost a good deal of weight in a few weeks. *Severity.* On admission (June 1932), on restricted carbohydrates, the resting blood-sugar was 0·25 g., and he was passing 10 g. glucose in 24 hours. Drowsy; severe ketosis. *Present treatment.* Diet: total calories, 1772: calories per kg., 34; C. 100, P. 60, F. 120. Insulin: 12 units b.d. *Present condition.* Usual resting blood-sugar: 0·07–0·10. Usually sugar-free. Weight: 8 st. Height: 5 ft. 0½ in. Activity normal.

CASE 18.—Boy aged 9½. Scarlet fever at 7. One brother aged 24 has severe diabetes treated with insulin. In January 1933 he developed thirst and polyuria, became out of sorts and seemed to be losing weight. *Severity.* Urine contained sugar and acetone in large amounts. Sugar tolerance: F.B.S., 0·13; (25 g. glucose) 0·21, 0·25, 0·30, 0·26, 0·25. *Present treatment.* Diet: total calories, 1720; calories per kg., 54; C. 165, P. 50, F. 90. Insulin: 12 units b.d. *Present condition.* Usual resting blood-sugar: 0·06–0·10. Usually sugar-free. Weight: 5 st. Height: 4 ft. 8 in. Activity normal.

Age-incidence.—It will be seen from these notes that the diabetes came on in one case at 3, in one at 4, in one at 6, in three at 7, in two at 9, in one at 10, in one at 11, in three at 12, in four at 13, and in one at 14.

THE CAUSE

The disease is familial in six patients but evidence of heredity could be traced in only one of these. Cases 10 and 11 are brother and sister. The former also has double cataract and the latter severe congenital heart disease. A great-aunt in this family is also said to have had diabetes. Case 5 had a brother who died of acute diabetes at 18. Case 3 had a brother who died of diabetes at 25. Case 18 has an older brother with severe diabetes. Case 16 has two first cousins on the father's side with severe diabetes. In the remainder a family history of diabetes was known in only one, and the families appear to be healthy in other respects. These cases support Cammidge's view that diabetes is more likely to be grave when it is transmitted as a recessive characteristic. The manner of onset was broadly the same in all cases but in one the development of cataracts was the first symptom which led to diagnosis.

Predisposing causes.—All the children except the one with congenital heart disease and Case 3 appeared to be in normal health until the onset. Of the infectious diseases mumps was an immediate prelude to the onset of symptoms of very severe diabetes in three. Case 2 had mumps in June, 1925, at the age of 12, followed a few days later by slight epigastric discomfort. A few weeks later thirst and polyuria developed. This persisted and two months after he had a resting blood-sugar of 0·28 and passed 113 g. of glucose in 24 hours. He now needs 80 units of insulin a day. Case 4, at the age of 7, developed "influenza" followed by mumps. The attack was a mild one but was accompanied by some abdominal pain which lasted for eight days. Three weeks after this he developed sudden thirst and polyuria and he was found on examination to have severe diabetes. Now, at the age of 13, he requires 50 units of insulin a day. Case 14, at the age of 13, developed a moderately severe attack of mumps which left him out of sorts for three weeks. Severe thirst and polyuria then developed, and three days later he sank into diabetic coma with a blood-sugar of 0·6 per cent., from which he did not recover. He never complained of any abdominal symptoms.

Acute pancreatitis is a rare complication of mumps but has been recorded by many authors: Simonin[1] referred to 10, Moutier[2] 74, Freund[3] 8, Dopter[4] 45, and Brahdy and Scheffer[5] 13. Post-mortem examinations are recorded by Lemoine and Lapasset,[6] Sabrazes,[7] and by James.[8] In these three cases extensive changes were found throughout the whole gland and islet tissue was also involved. Glycosuria and hyperglycæmia are mentioned as being present in some of the more severe cases, but diabetes as a sequel is apparently very rare. Cases are described by Harris,[9] Barbieri,[10] Gilhespy and Holden,[11] Patrick,[12] and Dick.[13]

Harris's patient was a man, aged 40, who developed thirst, hunger, and polyuria one month after the onset of an attack of uncomplicated mumps. These symptoms gradually increased and three years later he had lost 30 pounds in weight, and was passing 6440 c.cm. of urine in the day containing 4·6 per cent. of glucose. There is no record of abdominal pain at the time of the attack of mumps.

Barbieri's case was a boy, aged 6, who developed epigastric pain, vomiting, and diarrhœa six days after the onset of mumps, and hunger, thirst and severe glycosuria a few days later. These symptoms subsided after 15 days.

Gilhespy's patient was a boy, aged 16, who, on the fourth day of an attack of mumps, developed thirst and polyuria, and when seen a few weeks afterwards had severe diabetes. He also had tuberculosis and died five months later.

Patrick's patient was a girl, aged 8, who had an uncomplicated attack of mumps without abdominal pain, and two weeks after the onset developed polyuria followed by thirst and hunger. Five weeks after the onset of the mumps she was admitted to hospital in diabetic coma with 8 per cent. of sugar in the urine and died in 36 hours in spite of insulin treatment.

Dick's patient was a girl, aged 13, who within a few months of a moderately severe attack of mumps without abdominal pain was found to be wasted, and to have severe diabetes.

Gundersen[14] states that after epidemics of mumps there is a rise in the death-rate from severe diabetes in the young age-group. Joslin[15] says: "In only a few instances have I been able to associate infectious diseases with diabetes. In fact the more seriously I search for them the more rarely do I find trustworthy instances." Of the eight cases cited here of diabetes following mumps there was only one in which symptoms suggestive of severe pancreatitis were present and this was the mildest case of diabetes. In the other seven, abdominal symptoms were absent or very slight.

In this series the onset was not associated with any other specific fevers. Mild infections preceded the onset of symptoms in three cases and in three others appeared to have provoked an exacerbation of symptoms which led to diagnosis. In the remainder, however, the diabetes appears to have come on silently, and usually with great rapidity and severity, in children who had previously been in perfect health.

SEVERITY

The severity of the disease in children is well shown by the sugar-tolerance curves which have been done in these cases. It is true that many of these curves were taken after the condition had been present for several years, but there is evidence that the sugar tolerance is usually severely impaired within a few weeks or days of the first onset of symptoms and the suddenness of the onset of symptoms in some cases is very suggestive of sudden failure.

Case 13 was healthy until she was 4 years old. She then seemed out of sorts for a few weeks, developed a feverish cold with thirst and polyuria, and the next day becomes comatose with a blood-sugar of 0·49. Case 7 was healthy until he was 10. He then became thirsty for a few weeks, scalded his foot slightly, and was admitted to hospital four days later on the verge of coma with a blood-sugar of 0·38 per cent. Case 12 was well until she was 3 years old. She then developed frequency and became pale and out of sorts. Three weeks after the onset her doctor found sugar in her urine and on admission a day later the specific gravity of the urine was 1050 and contained a great deal of sugar and acetone, and her resting blood-sugar was 0·26 per cent. She was then passing between 22 and 36 g. of glucose in 24 hours.

Among these, there is no case which could be called mild and even those who attended a doctor as soon as could reasonably be expected were found to have gross impairment of sugar tolerance and ketosis.

Clinical and Laboratory Notes

A CASE OF ADDISON'S DISEASE TREATED WITH COMMON SALT

By W. Gordon Sears, M.D., M.R.C.P. Lond.

SENIOR ASSISTANT MEDICAL OFFICER, ST. GEORGE-IN-THE-EAST HOSPITAL, LONDON

A LEADING article in The Lancet of Jan. 20th, 1934, referred to the use of common salt in the treatment of Addison's disease, and gave an account of experimental work showing alteration in the amounts of inorganic bases present in the blood in adrenal dysfunction. In the following case opportunity was taken to investigate the concentration of the metallic bases in blood before and after the administration of sodium chloride by mouth. It is evident that no conclusions can be drawn from one set of figures in an isolated case, but the results are of interest in confirming the presence of abnormalities already described by the American workers.

The patient, a man aged 52, was admitted to St. George-in-the-East Hospital on March 10th, 1934. The diagnosis of Addison's disease was made at the London Hospital in 1927, and since then he has been in hospital on several occasions. In 1931 he received a course of injections of cortical extract which was followed by improvement in his general condition. He was readmitted in 1932 with symptoms of increasing weakness, anorexia, vomiting, giddiness, and precordial pain. (Blood-sugar 76 mg. per 100 c.cm.; Wassermann reaction negative.) A further course of cortical extract was given. His blood pressure at this time was 125/88 mm. Hg. (An abnormal feature of this case has been that the blood pressure has never been observed to be very low.) He remained fairly well for 14 months and was able to do some light work, but during four weeks before admission there had been recurrence of symptoms. He complained of increasing weakness, giddiness, and slight cough. He though that the pigmentation had increased in intensity.

On examination there was generalised pigmentation, excessive in the axillæ, nipples, and on the back of the neck. Some pigment was present in the buccal mucosa and in the palate. His blood pressure was 120/80. After a sample of blood had been taken for analysis he was given 60 grains of common salt daily by mouth in addition to the amount usually taken with meals, making a total of approximately 5 grammes per diem. A week later blood was again taken for examination. The blood pressure was found to have risen to 140/85. His general condition had improved, the extreme weakness had gone, and he was able to get about quite well. He stated that he was feeling as well as ever and wished to go home. He was advised to continue taking an increased amount of common salt daily.

I am indebted to Dr. A. B. Rosher, pathologist to the Mile End Group Laboratory, for undertaking the blood analysis and for his permission to utilise the results. The figures obtained are shown in the accompanying Table.

	Before taking NaCl.	After taking NaCl.	Normal.
Calcium	10·8	8·16	10·0
Potassium	56·0	16·0	16 to 22·0
Sodium	248·0	452·0	330·0
Magnesium	1·25	1·01	1·6
Chloride as Cl	268·0	455·0	300·0 to 500·0

All results are expressed as mg. per 100 c.cm. of blood.

It will be seen that the most striking variations from normal, before giving sodium chloride, are the low sodium and the increased potassium content of the blood. The administration of sodium chloride resulted in a reversal of this state. The blood sodium rose to above the normal level and the potassium decreased to the minimum normal figure. These results are in general agreement with those referred to in THE LANCET—namely, that in Addison's disease the sodium content of the blood is low and can be raised by the administration of sodium chloride by mouth. Although Loeb stated that the potassium balance in adrenalectomised dogs was undisturbed, Harrop, Soffer, Ellsworth, and Trescher found that potassium, calcium, and magnesium were all increased. In the present instance the figures for calcium and magnesium are approximately normal, but the potassium value shows considerable increase in the first specimen of blood taken. The period of observation was too short to arrive at any conclusion as to the real value of sodium chloride as a therapeutic agent in the treatment of Addison's disease, but the patient appeared to improve considerably and the systolic blood pressure rose 20 mm. Hg. The patient himself stated that he felt very much better and that the improvement had been as marked and rapid as on the previous occasions when he had been treated with cortical extract.

I am indebted to Mr. Alan Gairdner, medical superintendent of the hospital, for permission to publish the case.

LOOSE BODIES FROM A KNEE-JOINT

OSTEITIS DISSECANS

BY W. B. R. MONTEITH, M.A. Camb., F.R.C.S. Edin.

LOOSE bodies have long been recognised as one of the possible causes of functional disability of joints, and more particularly of the knee-joint. Mr. H. A. T. Fairbank[1] has recently discussed the pathology of osteitis dissecans, favouring the view that the morbid processes result directly from injury. In the following narrative the condition might more correctly be described as a sequel to osteitis dissecans rather than the actual condition itself. The complete renewal of functional ability following operation, in spite of about 36 years' lameness, seems further to show the importance of reminding ourselves, when dealing with a single stiff and painful joint, of this curable condition.

Mrs. A., aged 46, consulted me in December, 1932, because of weakness and recurrent swelling of the right knee, and inability to bend it. At the age of 10 she fell on a hard stone, and the knee had given trouble ever since. Six or seven weeks after this first injury she jumped off a gate, and felt "as if something shifted in the knee and then clicked back into place"; she fell down with the pain. Seven years ago (at the age of 39) she fell down a step, doubling the right leg under her. Since then she has been unable to kneel and the knee had frequently been greatly swollen. She had always been able to ride a bicycle in spite of the disability. The left knee had never caused trouble; all other joints were normal and there was no rheumatic family history.

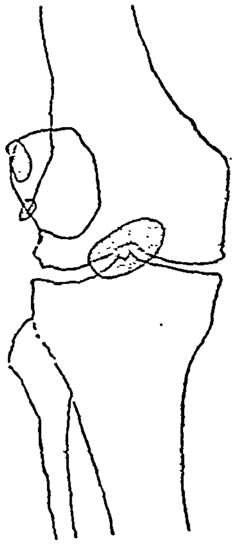

FIG. 1.—Tracing from radiogram of knee-joint, showing three loose bodies (stippled.)

On examination, the right knee was swollen and some fluid was present. Flexion was possible to a very small degree only on account of pain. A "loose body," the size of a pea, was felt on the lateral aspect of the external femoral condyle. While this body hardly seemed sufficient to account for the symptoms, it was supposed that it might sometimes lodge between the articular surfaces. The patient was admitted to the Butterfield Cottage Hospital, Bourne, and an X ray photograph was taken. Before photographing, the leg was extended and fixed on a splint, to prevent any shifting of a loose body between the time of examination and the subsequent operation. The photograph showed not one but *three* loose bodies, the largest lying between the femoral condyles and being obviously the cause of the symptoms. (Fig. 1.)

I operated the next day. The movable body lying over the external condyle was transfixed by a straight needle passing through the skin. A vertical incision 4½ in. in length was made over the lateral aspect of the knee-joint and the needle was followed down to the "body," which was removed. (Fig. 2.) The knee was then slowly flexed and a gloved finger introduced into the joint was able to feel the largest body sliding up the inclined plane of the condyle. Removal was effected by means of curved volsellum forceps. It may be worthy of note that whereas the largest body and one of the others was free within the joint cavity, the third was attached to the bone by a vascular pedicle. The usual precaution of tight bandaging was taken to prevent effusion into the joint. The wound healed perfectly; the patient was in hospital three weeks; and now, after eight months, the joint is faultless.

---

[1] Brit. Jour. Surg., 1933, xxi., 67.

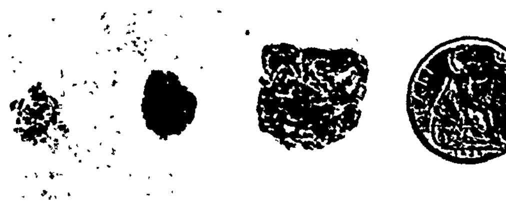

FIG. 2.—The loose bodies, beside a halfpenny.

In this case no "crater" in bone was visible in the X ray photograph, such as is described as occurring in osteitis dissecans, but the length of history might surely quite well account for the absence of that appearance. The patient, quite unprompted, gave a history of three distinct injuries. It seems to me that on one of these occasions a small area of bone and cartilage necrosis was caused, such as is described in osteitis dissecans and that at one of the latter accidents this was displaced into the joint cavity. Alternatively, each body might have been caused by a separate injury.

The absolute necessity of taking an X ray photograph when a loose body is suspected, even if one can be felt, seems to be well shown. Also, the completeness of the recovery in spite of the patient's age and the long history of disability is interesting.

Bourne, Lincs.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF EPIDEMIOLOGY AND SECTION OF PSYCHIATRY

At a joint meeting held on April 27th, Dr. J. D. Rolleston being in the chair, a discussion on the value of the

Treatment of Mental Deficiency

was opened by Dr. F. C. Shrubsall for the section of epidemiology and state medicine, and by Dr. W. Rees Thomas and Dr. Noel Burke for the section of psychiatry.

Treatment, Dr. Shrubsall explained, included training and supervision for the encouragement of such abilities as existed and the stabilisation of character. Its value meant the value to the individual sufferer, to the other members of his family, to the community at large, and to the local authority. If social and educational treatment were to be of value, it was of the utmost importance that the process of ascertainment should be as complete as possible. At the end of 1933 London had actually been dealing with about 20,000 cases and had a knowledge of some 11,000 others, a total which roughly corresponded with the estimate of the Wood Committee. Every year a number of defectives had to pass from supervision into institutional care as their parents died or became unable to provide a home for them. These persons would in any case need some form of public assistance of a residential character, and so the choice for the local authority was not between providing institutions and nothing, but between providing certified institutions and public assistance institutions. For many reasons the certified institutions were more suitable and more economical.

Perhaps the most valuable activity of institutional treatment was the prolonged care of low-grade cases, and of patients of higher mentality who were handicapped by physical defects. It was a great boon to such sufferers to be kept away from comparison with the relatively normal inmates of public assistance institutions. Physically defective patients imposed extra cost on the latter institutions, and many defectives if not in certified institutions would have to remain in hospitals for chronic cases, a nuisance to their fellow-patients and the staff. For defectives who were able to work, a certified institution offered a safe asylum while protecting the community against crime and the propagation of undesirable offspring, and enabling the patients to contribute towards their own maintenance and to gain the happiness which resulted from useful occupation. The cost of such institutions was little more than that of an ordinary public assistance institution. A certain number of higher-grade patients with more emotional control acquired from training sufficient stability of character to be restored to life in the community, first on licence and subsequently on discharge. There was thus a definite flow of persons back to community life, so that an additional expenditure of three shillings to six shillings a week brought the community a substantial dividend. Guardianship cost from ten shillings to fifteen shillings a week and provided a closer degree of control than would be available if the family simply received out-relief. Supervision helped the family and the patient, enabled closer care to be provided at once if necessary, and assisted the younger persons to obtain employment.

Special schools excluded the lower grades and the merely dull or backward. Higher-grade cases leaving special schools could secure posts more readily and at a higher rate of pay than children from the lower forms of ordinary elementary schools. Figures from one school over a period of 14 years showed 86 per cent. of employable and 82 per cent. of employed ex-pupils. Moreover, of 168 mentally defective adults charged before magistrates in the last two years, 65 only had attended special schools; considering that over 700 defectives left special schools in London every year, the proportion was a low one. The danger that defectives left in the community might produce large numbers of defective children was less than had been stated. According to the Brock Report, the abnormal fertility of defectives was largely mythical and mortality among their children was unusually high. Moreover, the children of defectives generally had a mentality superior to that of their defective parents.

Medical or surgical treatment offered little prospect of success; the treatment of syphilis at an early age did something to reduce the number of patients who developed specific encephalitis later, and a few cretins were benefited by thyroid treatment. The Mental Deficiency Acts and Section 55 of the Education Act might, said Dr. Shrubsall, be compared to a filter which, by removing insoluble residues, enabled the social machine to function more smoothly. Defective children in ordinary school classes held back the remainder or were left to stagnate; a probation officer saddled with a group of mental defectives could neither place them properly nor devote the necessary time to his other charges. Many petty offences by defectives were due to stupid rather than deliberately antisocial acts. Public hospitals were relieved of helpless and dirty patients, and families were relieved of children who would otherwise be a constant anxiety. The public, in short, received a return for its expenditure. "It is wise economy," quoted Dr. Shrubsall, "to spend more to waste less."

Dr. **Thomas** pointed out that the value of treatment depended on the object in view. Little progress had been made in research into causation, but considerable success had been achieved in training patients to carry on an independent social existence. The advisability of training a defective who could not be expected to become wholly or partly self-supporting was often questioned, but mere isolation and handling without any form of treatment or any of the amenities of life were not a possible solution but a remnant of the Middle Ages. Colony life enabled patients and staff alike to live up to their full capacity, and gave the patient the happiness of relative success. Leave of absence on licence provided an excellent method of deciding the ability of a patient to live in the community. Visitors who taught harassed parents the elements of how to train defectives, and possibly provided some material, did much good. Where a number of patients could be collected, occupational and industrial centres could be conducted with much benefit. The nation should regard its progress in the treatment of defectives as a compliment to its good sense and medical instinct. Expressions of incompetence formed a large part of the vocabulary of defectives living under unsuitable conditions, and training often prevented them from becoming a menace to society.

Dr. **Burke** stressed the importance of treating the individual rather than the condition in order to relieve the feeling of inferiority which came from competition with the normal world. It was important, he said, to secure for those who were physically handicapped some sort of physical success, no matter how rudimentary, in occupation or handicraft. Training in reasonableness, self-control, and trustworthiness could be given through the medium of the Scout or Guide movement. The mental hospital environment was definitely bad for defectives, and produced a type recognisable by a peculiar dullness and lethargy.

DISCUSSION

Dr. **Ralph Williams** pointed out that mental defectives were often more efficient factory workers than normal persons, because of their greater capacity to perform monotonous tasks.

Dr. **Letitia Fairfield** said that the criminal defective, to whom so much attention had been drawn, was the untrained defective, who had not been through the special school. London had made every effort to ascertain these defective criminals, and—with all the talk about this menace to society—the numbers reported every year hardly amounted to a full morning's work at one police-court. A thorough comb-out of the casual wards had found last year only two defectives. The problem of training would continue to be urgent, however drastically defectives were dealt with by sterilisation and other means.

Dr. **G. de M. Rudolf** narrated that in 1930 Brentry House, near Bristol, had instituted a system of behaviour records and new methods of handling patients to give them the utmost freedom and responsibility. The figures of misbehaviour had fallen amazingly as a result of the new régime.

Dr. **Isabel Wilson** remarked that money spent on training defectives went very largely to relieving their homes and getting better treatment for the other children. There was, she thought, too great a tendency to teach defectives in institutions facts about institution rather than about community life.

Dr. **Murdo Mackenzie** considered it a pity that the special schools were associated with the phrase "mentally deficient," which had an unfavourable effect on parents.

Dr. **W. A. Potts** quoted figures from Birmingham which showed that the incidence of high-grade mental deficiency closely followed the death-rate in the various wards of the city.

Dr. **C. J. C. Earl** said that prolonged residence in an institution did not fit a patient for community life unless he were trained to more or less complete freedom. He pleaded for closer psychiatric investigation and treatment of defectives.

Sir **W. Dalrymple-Champneys** regarded the modern treatment of defectives as evidence of the progress of the human race, and doubted whether it could have been achieved in any but the Christian era.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

A meeting of this society was held at Liverpool on April 6th with Prof. **Daniel Dougal**, the president, in the chair.

Breech Presentation

Dr. **J. W. Burns**, reading a paper by himself and Mr. **C. M. Marshall**, contended that much of the text-book teaching on this subject is unsupported by facts—with the result that there was a fœtal mortality of 15 to 30 per cent. in breech cases throughout the country. Breech labour, he said, carries great risks both for mother and child, but attempts to prevent it by external version should not be made as a routine, since manipulation of the uterus is liable to separate the placenta. In management of the labour itself everything possible must be done to prevent early rupture of the membranes.

The patient is put to bed as soon as labour has started. She is encouraged not to bear down during the pains, and the usual enema or purgative is withheld. One vaginal examination is made to find out whether the cord is presenting. A comfortable binder (the "labour belt" devised by Sister Miller of the Liverpool Maternity Hospital) is applied; it has numerous buckles and straps which can be readjusted from time to time. There is much to be said for inserting a sausage-shaped balloon filled with water into the vagina to support the forewaters until the os is fully dilated. (This closely resembles the bag suggested by Farquhar Murray for the treatment of placenta prævia.) During the first stage the patient is given nourishing drinks. She is encouraged to rest between pains. Bromides and chloral are useful, especially the latter.

When the membranes rupture a vaginal examination is made to find out whether the cord is prolapsed, how much dilated the cervix is, and whether the legs are extended, if this has not been discovered in the antenatal period. Nothing more is done until the breech appears at the vulva, except that the labour belt is adjusted periodically from above down as the uterus descends. When the breech appears the patient is placed in the cross-bed position and a Clover's crutch is applied: the binder is tightened. No handling of the fundus is allowed, because of the danger of causing premature separation of the placenta. The attendant feels for the feet as soon as the buttocks are born and gently lifts them over the perineum; he takes care not to pull on the limbs. The umbilicus usually follows with the next pain. The cord is found and drawn down so that further descent of the infant may not cause tension on it. (Dr. Burns thought it high time that teachers refrained from instructing pupils to endeavour to place the cord in some position where it will not be subjected to pressure. "This is an impossibility and no one nowadays attempts it.") After the next pain a finger is inserted to find out whether the arms are in the pelvis; if so, they are gently drawn down. The shoulders follow with the next pain. At this stage the head is entering the brim. The attendant supports the body and allows internal rotation of the head to occur; as soon as the occiput has come forward he allows the body to hang from the vulva. This brings about flexion of the head and brings the nape of the neck well into the subpubic angle.

The mother's perineum and soft tissues act as the fulcrum. The suboccipital area of the infant's skull is in contact with either the back of the symphysis or the descending rami of the pubes. The child's weight acting through the neck and across the fulcrum forces the head to rotate on its horizontal axis—i.e., flexion is induced. This method of producing flexion acts whether the head is just above the brim or whether it has entered the pelvic cavity. If the head is at the brim, this method has several advantages; no traction is required by the operator; the shortest diameters of the child's head are rolled through the brim (i.e., the suboccipito-frontal and suboccipito-bregmatic): the minimum of force necessary to produce flexion of the head is used; undue haste in delivery is avoided; there is no need for fundal or suprapubic pressure, and the danger of premature separation of the placenta is thus minimised. If the head is in the cavity flexion of the head is still necessary, so that the shortest diameters of the child's head may distend the perineum, and thus the risk of tearing the perineum or damaging the head may be minimised. By allowing the baby to hang from the vulva for one or two minutes the nape of the neck is brought more into the subpubic angle without the use of undue force. The force employed is limited by the child's body-weight.

As soon as the suboccipital area of the head can be seen in the subpubic angle delivery can be brought about by lifting the child up towards the mother's abdomen.

The operator should stand on the right side of the patient, and taking the child's feet in his right hand exert tension on the body from the moment the feet are seized. This tension must be enough to keep the neck of the child taut, and it is maintained while the legs and body are lifted in an arc until the body is vertical. By this manœuvre the suboccipital area is made to rotate around the point of contact between the skull and the pubic rami, so that the suboccipito-mental diameter distends the perineum, then the suboccipito-frontal, and lastly the suboccipito-bregmatic. If tension is not maintained throughout this manœuvre the child's head simply rotates within the pelvis, the occiput recedes and the perineum is not distended. Further, the child's neck is merely bent, and much damage may be done to the structures in it without the head being delivered.

Mr. MARSHALL described the technique he used in delivering the frank breech in primigravidæ. As soon as the anterior buttock is showing the mother is put in the lithotomy position, the whole perineum is infiltrated with about 50 c.cm. of 0·5 per cent. novocain solution, the index-finger is placed in the anterior groin, and descent with the pains is aided by traction. When the anterior buttock is showing well, and the posterior strongly bulging the perineum, a mediolateral episiotomy is performed. The posterior groin is then reached if necessary, and the buttocks are born. Chloroform is administered on an open mask, and the extraction is completed. When the arms have been brought down the body is allowed to hang from the vulva for some moments. In rather less than half the cases the amount of neck visible lengthens, and the head enters the pelvic cavity. The head is then delivered by Dr. Burns's method. If the head does not enter readily or there is delay in its descent through the passage, pressure with the free hand is applied to the head just above the pubes.

As a rule, Mr. Marshall said, delivery was easily effected by these methods. Forceps were used in a few of the very early cases, but were now very seldom required. In 33 consecutive breech deliveries in primigravidæ there had been only one stillborn child: this was in one of the early cases and one of 27 in which the legs were extended; the head was difficult to extract, and Mauriceau's grip was used to bring it through the outlet. The average weight of the babies was 7 lb. The perineal anæsthesia was useful because it allowed the mother to bear down with less pain and apprehension, because groin traction was almost painless, and because episiotomy could be done at any time without resorting to general anæsthesia. To patience and the above methods Mr. Marshall attributed the small number of cases in which it had been necessary to decompose the extended breech and extract. This was done in only two cases: in one groin traction had failed, and in the other unsuccessful attempts had been made to deliver before admission.

In the summing up it was emphasised that no midwife should be allowed to undertake a breech labour unassisted: she should send the patient to her own family doctor or to an institution as soon as the diagnosis was made.

Fluid Restriction in Pregnancy Toxæmia

Mr. W. J. CHISNALL read a paper on the treatment of albuminuria of pregnancy associated with hypertension, according to the method advocated by J. O. Arnold and Temple Fay.[1] In pre-eclampsia, he said, there was a progressive diminution in urinary output, associated with storage of fluid in the body. The object of the treatment was to correct the state of hydration by reducing the fluid intake, so that it never exceeded the urinary output of the day before. Accessory measures adopted in some of the cases with a view to reducing intracranial tension were the intravenous injection of glucose (40 c.cm. of a 20 per cent. solution) or magnesium sulphate (20 c.cm. of a 20 per cent. solution) and spinal drainage. These methods were used only if high blood pressure, headache, and dimness of vision were not quickly responding to reduced fluid intake.

A standard diet is employed. Its caloric value is 1500 and it contains 70 g. protein, 30 g. fat, 240 g. carbohydrate, and 3 g. salt. Beef or mutton, cod or hake, boiled puddings, bread and butter, tea and cocoa are allowed. Meals are taken at 8 A.M., 12 noon, and 4 P.M. and a drink is given at 8 P.M. No eating or drinking between meals is permitted. When a patient is admitted a history is taken and a complete examination made. An arbitrary figure is chosen for fluid intake for the first 24 hours, from 600 c.cm. in a mild case down to nil for a severe case. All urine passed is collected and measured. A dose of mist. alba is given each morning before breakfast. On the morning after admission a catheter specimen of the urine is obtained, and a simple enema is given. A sample of the 24 hours specimen is put up in an Esbach tube each night. After the first day, the amount of fluid allowed is equal to the urinary output for the previous day. If the patient is discharged undelivered, she is instructed to keep to the diet and fluids taken in hospital: she still takes the mist. alba every morning, and attends the antenatal clinic weekly. If improvement is only temporary or not adequate, labour is induced by the bougie method.

---

[1] Surg., Gyn., and Obst., 1932, lv., 129; see THE LANCET 1932, ii., 639.

At the Walton Hospital, Liverpool, between October, 1932, and October, 1933, the method had been applied, Mr. Chisnall said, to 39 cases of pre-eclampsia, defined as a disorder of pregnancy associated with albuminuria, œdema, and hypertension, without evidence of previous nephritis. Among them were 28 primigravidæ. Medical treatment sufficed in 36 cases, but in the other 3 (all primigravidæ) labour was induced because improvement was not maintained. The treatment in favourable cases was followed by reduction of blood pressure to normal figures, disappearance of œdema, diminution of albuminuria, and cessation of symptoms. In all cases a healthy live child was born; in 36 the mother was cured, and in 3 the symptoms recurred after partial relief. Despite the restricted fluid intake a progressive increase in the daily volume of urine occurred, lasting from 4 to 10 days, after which the volume remained steady. This was equal to the volume of fluid which could be allowed without storage occurring. If the intake went beyond this figure the symptoms tended to recur.

REVIEWS AND NOTICES OF BOOKS

Recent Advances in Medicine

Clinical, Laboratory, Therapeutic. Seventh edition. By G. E. BEAUMONT, D.M., F.R.C.P., and E. C. DODDS, M.V.O., M.D., F.R.C.P. London: J. and A. Churchill. 1934. Pp. 485. 12*s.* 6*d.*

THE great success which this book has achieved during its ten years of life has been well deserved. A number of notable additions appear in the present issue. The first chapter now includes an admirable review of the present position of the sex homones—to the elucidation of which Prof. Dodds has largely contributed—and the vitamins, and ends with an account of the parathyroids and their relation to calcium metabolism. In the chapter on the kidneys the urea-clearance test is fully described, and a good account is given of the ketogenic diet in the treatment of urinary infections. The chapter on the stomach shows little alteration—a fair comment on the lack of progress made in the treatment of digestive disorders. A few additional illustrations are included in the account of the electrocardiograph, but the space allotted to this important branch of cardiology is still perhaps rather too small. Some help in the actual handling of the apparatus might be appreciated by readers who are well served with detail in the very full account of basal metabolism determinations. In the next edition a short section on radiography of the heart might also be included with advantage. The conclusion reached on sanocrysin in the treatment of pulmonary tuberculosis is that its value is doubtful, the immediate and ultimate results of its use being often disappointing. A number of changes are found in the laboratory methods of blood and urine examinations, which, as in previous editions, are given in enough detail to be of practical service.

"Recent Advances in Medicine" is now a standard work, which will continue to attract grateful readers in ever larger numbers.

A Diabetic Manual

Fifth edition. By ELLIOTT P. JOSLIN, M.D., Clinical Professor of Medicine, Harvard Medical School; Consulting Physician, Boston City Hospital. London: Henry Kimpton. 1934. Pp. 224. 10*s.* 6*d.*

IN its fifth edition this well-known manual has been considerably altered and greatly improved. The statistical data and charts supplied show the great improvement which has taken place in the treatment of diabetes, even as compared with the early and middle Banting period. Dr. Joslin does not advocate the extreme high carbohydrate-low fat diet, containing 250–350 g. of carbohydrate and 50 g. of fat, but uses a moderate one of 150 g. of carbohydrate and 90 to 100 g. of fat. The book offers useful hints on the control of the blood-sugar in difficult cases, and the treatment of coma is fully discussed. Dr. Joslin stresses the importance of the care of the feet, because the incidence of gangrene of the foot is still much too high. For the treatment of corns, the coöperation of a skilled chiropodist should be enlisted. The prevention of athlete's foot (ringworm of the toes) seems to require special precautions. The increasing incidence of diabetes among elderly persons, especially women, is disturbing. Dr. Joslin makes a strong plea for the avoidance of obesity, which he thinks is a prominent factor in its production.

The photographs of diabetic patients running, jumping, and the many sketches, provide an encouraging indication of the success of modern methods and make the book attractive to read.

Healthy Childhood

By HAROLD C. STUART, M.D., Assistant Professor of Pediatrics and Child Hygiene, Medical School and School of Public Health, Harvard University; Associate Physician, Children's Hospital, Boston, Massachusetts. London and New York: D. Appleton-Century Company Inc. 1933. Pp. 393. 8*s.* 6*d.*

THE convention in 1930 of the White House Conference on Child Health and Protection by President Hoover was an event which marked the recognition of the imperative call for a wider understanding of the physical and mental needs of childhood, and it is perhaps significant that the whole machinery of the conference was put in motion during a period of national crisis. It will be some considerable time before it will be at all possible to evaluate the work of the conference and before much of the data gathered by subcommittees can be generally assimilated. The "Children's Charter" (which Dr. Stuart quotes in full) may perhaps seem at first sight too idealistic and nebulous to serve as a working basis for investigation and research, but such a simple statement of the aims of the conference is definitely enlightening. The Century Childhood Library has been published with the object of rendering much of the material of the conference reports available to parents, and in this work Dr. Stuart, who was himself vice-chairman of the committee on the growth and development of the child in the medical section of the conference, has given a résumé of the physiology and development of the normal child, and of the aspects of preventive medicine concerned with the preservation of child health. Some indication of the scope of the book is given by the chapter concerned with the prevention of infectious diseases, in which the author describes the use of diphtheria toxin-antitoxin, the limitations of the Dick test, the employment not only of convalescent serum but of placental extracts in the prevention of measles, and refers to (though he does not recommend) the use of B C G. Whilst his treatment of the subject has necessitated the use of a considerable number of technical terms, Dr. Stuart has been singularly successful in presenting it in a form which should be perfectly clear to the educated layman. It is possible that even some of the medical profession may find in it a gentle reminder that they must polish their armour if they are not to be caught napping by their patients' parents!

Marriage and Parenthood

Issued by the Marriage and Parenthood Committee of the Society of Friends. London: Friends Book Centre. 1934. Pp. 16. 3*d*.

THIS excellent little brochure contains four chapters entitled The Engagement, Marriage, Parenthood, and The Home. The author, whoever he is, deserves congratulation on the vision he has displayed in relating the new outlook of marriage and parenthood with the religious values in the perspective of which the Quaker believes all human aspirations should be viewed. From the spate of books, pamphlets, and leaflets dealing with the problems of human reproduction, this little document stands out by reason of its breadth, its understanding, and its sobriety. Doctors are often consulted by anxious parents as to what advice should be given to young people who are contemplating matrimony. They may even be puzzled to know what advice to give to their own children when in this predicament. This brochure is recommended, not as a source of information on physiological problems, but as a gentle reminder that, over and above the knowledge of sex psychology and physiology which so preoccupy us to-day, a successful and durable marriage makes spiritual demands which it is well to recognise beforehand.

A Text-book of the Practice of Medicine

Fourth edition. By Various Authors. Edited by FREDERICK W. PRICE, M.D., F.R.S. Edin., Consulting Physician to the Royal Northern Hospital; Senior Physician to National Hospital for Diseases of the Heart. London: Humphrey Milford, Oxford University Press. 1933. Pp. 1995. 36*s*.

IN the fourth edition of this popular work many articles have been largely rewritten, and the sections on the diseases of the spleen, blood, and lymphatic system entirely so. Amongst recent methods of treatment now included are the use of Felton's serum in pneumonia, of insulin and glucose in heart disease, and of the compound mercurial diuretics; a very brief reference without details is given to the ketogenic diet in coliform bacillus infections. A full account of idiopathic hypochromic anæmia is now supplied, and brief notes on the filtrable viruses, agranulocytosis, Simmonds's disease, amongst over 50 new subjects mentioned. Of the 13 new illustrations, which hardly come up to the standard of the text, five are orthodiagrams of the heart and two electrocardiograms. It was not easy to find any account of how an orthodiagram is taken or of the normal measurements of the heart as estimated by this means. The electrocardiograms are excellent and their interpretation clear and concise. It is interesting to note the reversion in this edition to the old names of Graves's disease and Hodgkin's disease in place of hyperthyroidism and lymphadenoma.

Dr. Price and his distinguished contributors may be assured that this edition is likely further to enhance the well-deserved reputation of their work.

The British Journal of Surgery

THE April issue (Vol. XXI., No. 84) contains the following papers: A Contribution to the Study of Pulmonary Lobectomy, by A. Graham Bryce (Manchester). An experimental investigation into removal of a lobe of the lung in the cat by the three-stage operation of producing adhesions, ligaturing the pedicle, and excision of the gangrenous lobe.—Multiple Carcinoma of the Colon, with Four Original Cases, by A. J. Cokkinis (London). The growths are regarded as being all of primary origin; their relationship to multiple adenomata is discussed, and their clinical significance is emphasised.—Some Experimental Observations bearing on the Etiology of Megacolon, by Harold Burrows (London). Injections of crystalline silica into the mesentery of the cæcum has been followed by cæcal enlargement. It is suggested that persistent irritation of the sympathetic nerve-supply is the cause.—The Pathology of Acute Strangulation of the Intestine, by Robt. L. Holt (Manchester). An experimental investigation to determine the parts played by perforation and peritonitis, by absorption of toxins, by withdrawal of blood from circulation, and by dehydration, in death from strangulation of the intestine.—Neurosurgery in the Treatment of Diseases of the Peripheral Blood-vessels, by D. J. MacMyn (Mayo Clinic). An outline of the views held and the treatment employed at the Mayo Clinic in certain vascular diseases, particularly in thrombo-angiitis obliterans and Raynaud's disease.—The Selenide Treatment of Cancer, by A. T. Todd (Bristol). An account of treatment by a combination of injection of a colloidal selenide preparation with X-radiation: the results in 155 cases of inoperable cancer (see p. 963).—Bilharzia Disease in England: the Cystoscopic Appearances of the Bilharzia Bladder Before and After Intravenous Injections of Sodium Antimony Tartrate, by J. B. Christopherson and R. Ogier Ward (London).—Spindle-celled Mesenteric Tumours, with Remarks on Similar Retroperitoneal Tumours, by H. A. Phillips (Melbourne). A discussion of the origin, pathology, and classification, with an account of six personal cases.—Observations on Pleural Absorption, by R. C. Brock (London). Observations on the factors influencing the absorption of fluid from the intact and inflamed pleura in rabbits, with a discussion of the clinical bearing of the results.—The Plan of the Visceral Nerves in the Lumbar and Sacral Outflows of the Autonomic Nervous System, by Hugh C. Trumble (Manchester). A description of the autonomic nervous system based on the work of Langley and Anderson together with numerous dissections made by the author. A less chaotic nomenclature than that current in recent literature is suggested.—Malignant Adenoma of the Prostate with secondary growths in the vertebral column simulating Pott's Disease, by W. E. Carnegie Dickson and T. R. Hill (London). The primary growth was very small. The bony metastases were completely osteoclastic, and the main symptoms were due to rapid involvement of the spinal cord.—Primary Carcinoma of the Liver: with report of a case successfully treated by Partial Hepatectomy, by A. Lawrence Abel (London). A comprehensive description of the disease as it appears in the literature, followed by a description of the treatment and pathology of a case.

The issue also contains accounts of some rare and obscure cases.

THE TEACHING OF SPEECH.—The price of Mr. Sibley Haycock's book, reviewed in our last issue (p. 902) is 7*s*. 6*d*. post free.

THE LANCET

LONDON: SATURDAY, MAY 5, 1934

THE G.M.C. ELECTION

Dr. H. Guy Dain was elected on Friday last a direct representative of the registered medical practitioners of England and Wales, thus filling the vacancy created by the death of Dr. Christine Murrell. Dr. Dain has been in active general practice in Birmingham for more than 36 years and is known by his colleagues as a careful, wise, and energetic practitioner. For the last 20 years he has taken part in medico-political work of various kinds and has held offices culminating at last in the chairmanship of the Insurance Acts Committee—a committee which, although it enjoys the generous hospitality of the British Medical Association, is in fact the executive committee of the Insurance Medical Service. His election should give satisfaction to the profession.

Before the result of this by-election was declared, steps had been taken for putting in train an electoral system under which the places occupied for the last five years by Sir Henry Brackenbury and Mr. Bishop Harman when they retire in the coming autumn should be filled. They are both under the Act capable of re-election, and, should they seek the suffrages of the constituency, the medical profession will not be unmindful of their services rendered on that body to the interests of the general practitioner and particularly of their efforts to secure some revision in the medical curriculum which will bring it more into line with the aims and needs of general practice. Now an electoral system which has returned to the General Medical Council three such useful representatives of the profession cannot lightly be criticised, but the fact remains that the method chosen has not brought them to their position by the free and unfettered vote of the medical profession. As regards Dr. Dain's election it did not really take place last Friday but last year, when a notice appeared in the supplement of the *British Medical Journal* of Dec. 23rd (page 315) stating that in connexion with the G.M.C. by-election, certain nominations were received for selection by the English and Welsh constituencies in the Representative Body of one candidate to receive the support of the Association. There followed the names of nine candidates and the voting resulted in Dr. Dain being selected. This was in actual fact the time when Dr. Dain's election was secured, for, as a member of the B.M.A. Council has pointed out, no private candidate could possibly have a chance of success against such a nominee. And the speaker went on to comment upon an election devoid of competition in which no candidate thought it worth while to address the electors, and one out of which all interest had been crushed. Might not these words fairly be applied to last week's election?

In the Marylebone division of the B.M.A., of which one of the retiring candidates is a member, the hon. secretary of the division summoned "a meeting of the whole profession" to consider the nomination of a candidate or candidates to be recommended for election. There are more than 700 members of the B.M.A. in the division, but the attendance at this meeting did not exceed 20, and although support was offered *nem. con.* to the two retiring candidates, free expression was given to the drawbacks of the electoral method and to the feeling that these meetings do not in fact register the choice of the medical profession at large. There are many people both within and without the Association who would like again to see a free nomination and election. It should certainly not reproduce the kind of uninformed scramble in which the election took occasionally in earlier times, and under the auspices of the B.M.A. a number of the factors conducing almost to chaos have been eliminated; but it is plain that the intention of the Medical Act of 1886 is not being strictly observed in the present procedure. No one would stand to gain more from a restitution of the importance of the election than the B.M.A. candidates themselves, who would then have the assurance that they are really representing the medical profession as a whole and not any section of it however influential.

PERFORATION OF PEPTIC ULCERS

Since immediate operation is by common consent the only treatment to be considered in the presence of acute perforation of a gastric or duodenal ulcer, an estimate of the prognosis must take into account, first, the immediate post-operative mortality; and secondly, the subsequent digestive history of survivors. Within the last three years several surgeons have collected the immediate and remote results of their cases. Taking together figures from the practice of surgeons working in Newcastle,[1] Manchester,[2] New York,[3] and Lyons,[4] we have before us the results obtained in over 500 cases treated according to modern surgical methods under good conditions. The average mortality over the 521 cases reported from four hospitals is 19·8 per cent. The type of operation is not always recorded, but of 277 cases in which simple suture, with or without drainage, was done, 43, or 15·5 per cent., were fatal, whereas in 201 treated by combined suture and immediate gastro-enterostomy the corresponding fatality-rate was 21·4 per cent. This difference appears to favour treatment by simple suture, but is not more than might have arisen by chance and cannot be regarded as significant. That simple suture gives remarkably good results is well known; in the Newcastle figures a series of 63 consecutive cases is recorded with only 3 deaths. On the other hand, in the Hôtel-Dieu in Lyons, where

[4] Creyssel, J., and de Mourques, J.: Rev. de Chir., 1933, lii., 627.

194 patients received treatment, gastro-enterostomy is almost the routine for perforation; in 25 cases only was simple suture done. Two hundred and forty-five case records come from the hospital practice in Newcastle and Manchester, and include only 30 cases subjected to gastro-enterostomy. Comparison of the results reached at the different centres reveals no consistent advantage of one method over the other. The presence of other important factors makes it difficult, however, to compare results; for instance, the proportion of cases seen within twelve hours of perforation varied between 60 and 80 per cent., and this factor must have an important influence upon the success or otherwise of operation.

In the figures reached by Mr. T. G. Illtyd James and Mr. N. M. Matheson elsewhere in this issue the rather higher fatality-rate is probably related to a fairly high incidence of perforations at or near the lesser curvature of the stomach, and also to a higher average age (half of the patients were in the fifth or sixth decades). That the fatality increases with increase of age is evident in the Lyons figures, which show a rate of 55 per cent. for ages over 60. Undoubtedly, however, the factor influencing it most is the length of time elapsing between the occurrence of the perforation and the operation. This has long been recognised and is emphasised by all surgeons. Combining the figures for all cases in the various series mentioned above in which the length of this interval has been recorded, we find that where the operation took place within twelve hours the fatality-rate is 8·1 per cent., whereas after that time it rises to 25·8. Of the 3 deaths in the 63 Newcastle cases 2 were in patients operated on more than twelve hours after perforations. In this particular series, 51 cases were treated by simple suture of the perforation within twelve hours, and among these there was only one death. The four authors agree that perforation is very much commoner in the region of the pylorus and the first part of the duodenum than it is elsewhere. Of 496 perforations whose site is recorded, 82 per cent. occurred in one or other of these sites. (Attempts to differentiate between the proportion in the duodenum and the pylorus are of little value, since at the operation it is often impossible to be certain of the exact position of the pyloric opening.) Selvaggi,[5] in a recently published paper confirming these figures, records 44 per cent. perforations in the duodenum and 34 per cent. pyloric or juxtapyloric—that is, a total of 78 per cent. in one or other of these regions. The knowledge that the chances are four to one that the perforation will be at an accessible site should encourage the inexperienced surgeon who is faced with the responsibility of dealing with such a case.

Shelley, Gilmour and Saint, Scotson, and Creyssel have all made serious efforts to trace the subsequent histories of patients, and their results tally closely. There has been a prevalent idea among surgeons that once an ulcer has perforated it gives very little further bother to the patient; in fact, that perforation is followed by healing in almost every case. The truth seems to be that somewhere between 20 and 30 per cent. of patients definitely require further treatment; 60 to 70 per cent. are said to have "slight indigestion" only or to be quite free of digestive symptoms. Scotson and Shelley give over 40 per cent. as symptom-free after suture only, and Gilmour and Saint just under 40 per cent. Shelley and Creyssel, on the other hand, both report 61 per cent. of "excellent results" after gastro-enterostomy. The terms "excellent results" and "slight indigestion" are, however, susceptible to various interpretations. Symptoms dismissed by a surgeon as slight indigestion may involve discomfort to the patient over a term of years and may suggest to a physician the presence of a chronic ulcer. It is doubtful whether there is enough evidence of better end-results after gastro-enterostomy to justify a more protracted and severe operation following such a serious emergency as perforation. Still less would most surgeons favour immediate gastrectomy; nevertheless at some of the most important clinics in central and eastern Europe immediate partial gastrectomy is being performed for perforated ulcer. Judine in Moscow (quoted by Gilmour) reports particularly good results from this procedure with a surprisingly low fatality (6 deaths in 47 cases). His results are a tribute to fine surgical technique, but few would favour such drastic methods for general adoption. It is more likely that the tendency in the future will be towards simple suture with more prolonged after-treatment on modern medical lines.

MEDICINE AND CRIME

Justices of the peace might profitably study the recent report of the Commissioners of Prisons (Cmd. 4553, 1*s.* 6*d.*). Two points made by the medical commissioner, Dr. Norwood East, deserve the attention of all courts of summary jurisdiction. The public conscience, we believe, would be shocked if it were known that magistrates either sentenced an insane person to imprisonment or passed sentence in any borderline case without taking into consideration the alleged offender's mental condition. Yet the medical commissioner's report indicates that both these practices survive. An old man, for instance, was remanded to prison on a charge of begging: on his reappearance at court the bench sentenced him to seven days' imprisonment although informed by the experienced medical officer of the prison that the man was insane. The medical officer of the prison to which the old man was sent confirmed his colleague's opinion, and took the necessary steps to have the prisoner dealt with as insane. It is apparently a not uncommon practice for magistrates, when convicting an offender and sending him to prison, to ask that his mental condition be kept under observation during the period of his sentence. This course, as Dr. East remarks, inevitably suggests that insane persons may have been sentenced to imprisonment when they ought rather to be dealt with as patients of unsound mind or else that they may have been punished without due regard to the mitigation which their mental condition might justify. The first point, then, that magistrates should bear in mind is that, where there is any doubt about an accused man's mental state, it is wrong to pass sentence until the doubt has been resolved. A second point is that courts of summary jurisdiction could greatly help the prison medical officer by giving him fuller information. To ask the medical officer to report on a prisoner at the termination of sentence without specifying the reasons for the request is a needless diffusion of the doctor's time. If the clerk of the court furnished a brief note of the facts connected with the offence, the man's previous conduct, his demeanour in court, and any available details of his family and personal history, the task of medical observation would be simplified and expedited, and the report would be the more useful. This common-sense coöperation in the discharge of a public duty (already established in some of the busiest courts) would be equally valuable at whatever stage a medical report is asked for. If, for example, the bench wants guidance because the accused has alleged a loss of memory, that fact ought obviously to be communicated to the medical officer along with the request for a report.

---

[5] Selvaggi, G., Ann. ital di Chir., 1933, xii., 41.

In another interesting passage Dr. NORWOOD EAST comments on misunderstandings about certification under the Mental Deficiency Acts. People interested in welfare and after-care work, it seems, are inclined to criticise doctors for not being more swift to certify in cases of persistent antisocial conduct. He reminds the critics that the certification of mental defectiveness cannot go beyond the statutory definition. In the language of Parliament there must be "a condition of arrested or incomplete development of mind existing before the age of 18 years, whether arising from inherent causes or induced by disease or injury." It is natural enough to argue that persistent delinquency is in itself evidence of mental defect, but the problem is not to be solved by automatic certification. In this connexion the medical commissioner gives three instances where there has been a turnover from misbehaviour to normal conduct. All might easily have been classified as cases of mental deficiency, but they turned out to be due, in one instance, to the mental conflicts of childhood afterwards replaced by harmony and maturity, in another to periodical physiological imbalance subsequently readjusted, in the third to the slowness of development of the patient which was eventually caught up. The turnover to normal conduct can sometimes be dated with reasonable precision; "if the former misbehaviour is due to mental defectiveness, we must assume that a mind whose development has been arrested for many years can suddenly overtake that arrest and grow to normality in a few hours; the assumption is contrary to general experience."

Few will now deny the significance of the mental and psychological aspects of crime. The Persistent Offenders Committee recommended that a medical psychologist should be attached to one or more penal establishments to carry out treatment in selected cases. There is plenty of material in our prisons. The examining board of the Royal Colleges, as Dr. EAST reminds us, has recognised the experience to be gained there. It has lately decided to accept twelve months' appointment as medical officer in one of four large remand prisons as the equivalent of twelve months' mental hospital practice required for the diploma in psychological medicine.

THE ACADEMIC ASSISTANCE COUNCIL[1]

A YEAR ago an Academic Assistance Council, including some of the most famous names in British science, literature, and art, was formed to assist university teachers and investigators "who on grounds of religion, political opinion, or race were unable to carry on their work in their own country." The council has received rather more than £13,000 in subscriptions. It has made maintenance grants to 49 scientists or scholars, has assisted in placing another 90 to whom grants from other sources were available, and has helped 39 others who had some resources of their own to find opportunities of work in universities. This is an excellent record of service, and some of the reports on the work of the exiles show how good is its quality. For instance, one referee says of the work of a physiologist, "I think it is possible that the work is of even wider significance than he at present realises himself. It opens up several subsidiary problems in general metabolism. It may well be revolutionary."

The immediate ground of action was, of course, the revolution in Germany, but the Council has most carefully abstained from taking advantage of temporary or permanent national prejudices, and its assistance has not been confined to German exiles. For that very reason, perhaps, its task is difficult. The intoxicated professor in Mr. H. G. WELLS's "The New Machiavelli," who maintained that hate and coarse thinking made a much better slogan than the hero's love and fine thinking, was a practical man. The ordinary citizen can be much more easily induced to mark his disapproval of some specific act of cruelty by "foreigners" than to take any very keen interest in so abstract a cause as that of academic freedom. Already the misfortunes of German intellectuals have lost their news value and it would need another Einstein to restore it. The burden must be shouldered by those educated men and women, a small percentage of the nation, but still amounting to many thousands, who realise what the higher education has meant for them and what horrors are in store for a world in which the principle of academic freedom has perished. Members of our profession are in no need of this warning, the whole history of our science and art abounds in illustrations. Nobody may be in danger of the fate of Dr. JOHN GEYNES who, in 1559, "was cited before the College for impugning the infallibility of Galen. On his acknowledgment of error, and humble recantation, signed with his own hand, he was received into the College." We no longer have to depend on criminals for the possibility of studying human anatomy, it is not even common to hold up experimental physiologists to mob execration. Our bulwark is the existence of a large number of liberally educated people; liberal education as distinct from mere erudition or technical skill, implies academic freedom, unrestricted freedom of intercourse between student and teacher, always provided the student be earnest and the teacher competent. It is because that ideal was held higher in Germany than anywhere else, that its temporary obscuration in Germany is of such importance. English intellectuals have praised, perhaps over-praised, the German universities so zealously, that there is some risk that the man in the street may draw disconcerting conclusions. He has been exhorted to copy German intellectual institutions for more than 50 years. But the Germans have changed their system. If they were so very right once, may they not be right again? Hence the duty of educated persons to support the cause for which the Academic Assistance Council stands is clear. Enlightened self interest as well as humanity show the path.

---

[1] The annual report of the Council was issued from its offices in Burlington House, London, W., on May 3rd.

ANNOTATIONS

A SAFE MILK-SUPPLY

THERE is at the moment a large and growing surplus of milk and, at the request of the Children's Minimum Committee, the Government are prepared to spend £500,000 to assist the provision of a daily milk ration for school-children. The Government also contemplate the spending of £750,000 to improve the milk-supply of the country. Opportunity is thus afforded of an increased consumption of milk, of improving the quality of milk produced, and of securing that the milk supplied shall be safe from disease. A special meeting of the Joint Tuberculosis Council was called on April 20th to discuss the question, the basis of discussion being provided by a memorandum prepared by Prof. G. S. Wilson. It was felt that in the incidence of tuberculosis of bovine origin we are behind other countries, notably the United States of America and Canada, and that the present occasion offered a unique chance for improvement. A resolution was passed welcoming the prospect of an increased milk consumption, but averring that the Government proposal to subsidise a milk ration for school-children should be supported only if the safety of the milk supplied is insured by adequate pasteurisation or boiling. Such an insured safety needs no advocacy. But all familiar with the problems—a greatly enlarged number of medical men and of the public we are glad to think—know the difficulties involved. Referring only to the question of pasteurisation, concerning which distinct differences of opinion prevail, attention must be drawn to the short clear words of Lord Dawson in a letter to the *Times* of Tuesday, reporting the views of the Royal College of Physicians of London on the subject. The College welcomes a daily ration of milk as important for the growth and health of children, affirms as considerable the risk of tuberculosis and other diseases following the consumption of raw milk, and concludes that the risk "could be obviated by the use of milk submitted to low temperature pasteurisation as defined in the official order," while pointing out that such pasteurisation does not materially alter the nutritive value. In this issue of THE LANCET an inquiry made by Mr. E. J. Pullinger, of the research institute of animal pathology of the Royal Veterinary College, gives the results of an investigation made to obtain further information into the extent to which milk on the market is contaminated with the organisms of tuberculosis and contagious bovine abortion. His report describes the methods adopted for testing and gives the arguments for arriving at valuable conclusions, one of which may be quoted in this connexion. It runs: Samples from 63 3000-gallon rail tanks were examined; all were contaminated with living tubercle bacilli and 53 with *Br. abortus*. In the corresponding milk samples after low temperature pasteurisation neither organism had survived.

FRENCH VIEWS ON RHEUMATISM

SINCE the last congress of the International League against Rheumatism, held in Paris in 1932, the French section of the League has greatly developed its organisation and has now produced a *Revue du Rheumatisme*. It is proposed to supplement the international *Acta Rheumatologica* by publishing periodically a selection from the large amount of material that is appearing month by month, particularly in France. The main objective of this review will be to issue well-considered and authoritative monographs on the various problems connected with the rheumatic diseases. We are glad to note that the work of rheumatologists in other countries, such as America, Germany, Sweden, and England, is given ample notice. Not only medical and therapeutic but social problems fall within its scope. Rheumatic disease has, in France also, a serious bearing on industrial welfare, and has even become an economic question. An interesting example of the medical-social activity that has sprung into existence in France in regard to crippling rheumatism is the Entr'aide des Rheumatisants, which has its headquarters in the Hôtel-Dieu. This was founded three years ago by a small group of voluntary workers, and has for its object to relieve the large numbers of bedridden and often destitute rheumatic persons "who are not seen because they cannot go out." The Entr'aide endeavours to discover their whereabouts, to provide a cure or at least some alleviation, to assist them financially as needed, and to obtain for them light work if possible and better conditions. The ultimate provision of special hospitals or homes is kept in view. Much can no doubt be done by governments, as in Sweden, to secure for the many sufferers from rheumatism the necessary medical and social services, at all stages of this long-drawn-out illness, but there is still much scope for personal and voluntary service in many directions, especially in crowded centres.

Four numbers of the new *Revue* have now appeared under the direction of various members of the French committee—the first by Prof. Besançon, chairman, with Dr. M.-P. Weil, of the committee; the second by Prof. Marcel Labbé, and the third by Prof. Etienne of Nancy. Besançon and Weil contribute a timely introduction to the pathology of the joints, in which the existing state of knowledge is impartially summarised and many moot points are discussed, such as the nutrition of articular cartilage. In another section the same writers present an interesting historical summary, showing the evolution of ideas on the nature of rheumatism. They are obliged to conclude that in spite of enormous efforts medical knowledge is scarcely yet at the beginning of the scientific phase, and that even clinical observation is wanting in precision and clarity. The long succession of medical writers and teachers have added fresh names to a complicated nomenclature more often than fresh knowledge. Although Hippocrates appears to have distinguished the arthritides from rheumatism, and rheumatism from gout, these early gains were lost in succeeding centuries. Sydenham in his time clearly defined gout, and like Cullen nearly a century later, returning to Hippocrates, recognised the independence of chronic articular rheumatism. These conceptions passing through many minds in the nineteenth century led on to the differentiation of rheumatoid and osteo-arthritis, which under various synonyms now rules in most countries. This cardinal distinction was emphasised by the British Ministry of Health in 1924. Besançon and Weil reflect the opinion of the French School in distinguishing between the infective arthritides and rheumatism, and regard rheumatic fever as a specific disease. Of rheumatoid arthritis the cause at present escapes all inquirers, but many factors probably operate and the influence of cold and damp is undeniable in predisposed persons.

Since the problem of causation is still unsolved, treatment however successful and approved by experience must still be called empirical. Iodine, sulphur, physical treatment, and waters hold the ground, the two last being, in the view of the French committee, the basis of the treatment of chronic rheumatism. Following Pemberton they favour the hypothesis that these agencies modify the circulation and nutrition through the sympathetic system. Opotherapy has its place in the arthritis of women and chrysotherapy with preparations of gold has a probable value on the analogy of its good results in tuberculosis. According to a prevalent French view, to which good observers in other countries are inclined, some forms of rheumatoid arthritis are at all events para-tuberculous.

The new reviews, issued under the auspices of acknowledged leaders in the medical profession in France, should help to increase the clarity and precision of statement for which in the scientific field that country is distinguished.

ANÆSTHESIA IN URINARY SURGERY

The diversity of opinion on the best method of anæsthesia for cystoscopy was a feature of the discussion on anæsthesia in urinary surgery, held at the Royal Society of Medicine on April 26th. Dr. H. W. Featherstone's opening address covered a wide field, and included in a critical survey all the drugs and methods commonly used. For cystoscopy he himself preferred some form of local anæsthesia and in this he was warmly supported by some of the succeeding speakers, the agent especially favoured being cocaine in 0·5 per cent. solution with 0·5 per cent. bicarbonate of soda. It was maintained by some that novocain was useless in the urethra; others attributed failure with this drug to the use of too weak solutions, the introduction of the endoscope too soon after the injection of the solution, or the Trendelenburg position which stretched parts that should be relaxed. In direct opposition to advocates of local measures was Prof. A. C. Pannett, the second speaker, who expressed a horror of carrying out endoscopy except under general anæsthesia, preferably gas-and-oxygen. Those who differed from him took the attitude that general anæsthesia was impossible in busy urological out-patient departments where very many cystoscopies had to be performed from considerations both of money and of time. Moreover, unless gas and oxygen for this purpose was given with the greatest skill the patient's straining tended to force the endoscope out, and moreover the view was liable to be obscured by congestion. A sudden cough or movement on the patient's part might bump the instrument against the surgeon's eye; surgeons did not often realise, said one speaker, what they owed to anæsthetists in immunity from black eyes after cystoscopy. With regard to pre-medication, several speakers pointed out how easily this practice might interfere with the value of the inspection by delaying or preventing efflux from the ureters. For minor procedures, including cystoscopy, the use of a small dose of a local anæsthetic inserted intrathecally at a low interspace had many advocates among those who had tried the method in out-patient practice with satisfactory results. An injection of 2 c.cm. of a 1 in 200 percaine solution, with the patient sitting up, had given, it was said, excellent results.

An alternative suggested was percaine in 1 in 500 solution as a local analgesic in the urethra for cystoscopy. If a few minutes were allowed to elapse after injection, and some of the solution was massaged into the posterior urethra, excellent analgesia was said to be obtained. The value of small intrathecal injection low in the spinal column before washing out the bladder had been found of especial value in acute cystitis affecting old women.

With regard to prostatectomy the preponderance of opinion was in favour of spinal analgesia with or without a basal narcotic, though here too there were advocates of gas-and-oxygen assisted by a basal narcotic, or with ether added as necessary. One authority disliked spinal injection and relied on local injection of 0·5 per cent. novocain into four points of the rectus sheath in order to secure the necessary relaxation. Most of those who alluded to the question preferred spinal to other methods for the removal of tuberculous kidney; and all seemed agreed on the need for complete insensibility of the tuberculous bladder when this was being examined.

AMENITIES AT A L.C.C. HOSPITAL

Lord Snell's first official act as newly elected chairman of the London County Council was to open last Friday a new reception block at St. Giles' Hospital, Camberwell. This hospital was one of those appropriated by the Council three years ago and, as was indicated to the guests at the opening ceremony, this appropriation has facilitated the admission of patients other than poor-law patients—of persons, that is, in the category of what may be termed the *lower paid wage-earners and their families.* Secondly municipal patients may, if suitable, be admitted on the certificate of their own attendant medical practitioner, and finally any urgent case is admitted at the medical superintendent's discretion. These new aims have introduced a very different atmosphere into the hospital of St. Giles and have required the provision of a reception block with all the facilities usual in a voluntary hospital. The upper floor of the new building provides quarters for a senior and four assistant medical officers; the ground floor is given up entirely to out-patients including antenatal cases; there is a theatre for minor operations and a new dispensary which will serve both out-patients and district medical work. A new and attractive entrance, with a porter's room adjoining, emphasises the attempt to mollify the first contact of illness to the sick poor of the neighbourhood. Mr. Somerville Hastings who, as chairman of the L.C.C. hospitals and medical services committee, supported Lord Snell, said it was his task to make patients comfortable and happy during their stay in hospital. Illness anyhow was an unpleasant time; in the past a standard had been set by the voluntary hospitals, but these, short of funds as they always were, had always put essentials first. Comfort was to be the note of the developing L.C.C. hospitals; at Camberwell, Lord Snell added, other amenities were to come—lifts, automatic house telephones, and cold storage were the next items contemplated. The honours of the occasion went easily to the nurses to whom each several speaker addressed his attention; the deputy-chairman of the Council remarked that any nurse was happy to be in so progressive a service, one in which merit surely led to promotion. The ideals so freely set out on this occasion will, if realised, provide Camberwell with a very agreeable hospital of its own.

THE OLDEST MEDICAL SYSTEM[1]

How far does medicine, as it develops, reflect the social conditions of a country would be a difficult question enough to answer in regard to our own country, where back history can be definitely ascertained and where dates can be put against the various advances in medicine corresponding with, for example, the general scientific progress of the world, the relations between our own and continental schools of thought, and the simultaneous reorganisation in the western world of ideals and performances following upon fundamental discoveries. Even so, to trace in any definite way connexions between effective legislation and social behaviour would be an elaborate task and the conclusions arrived at would frequently be diverse in the minds of many thinkers. But when the question is placed before the reader in connexion with the medicine of China, of which contemporary records exist from nearly 3000 B.C., he would be bold, it might be thought, who should attempt to trace the connexions between Chinese medicine and Chinese civilisation, so vast is that country, so old are its systems, and so various are the races which, by interpenetration and conquest, have fused themselves into what is termed the Chinese nation. Still in his small book Dr. Morse provides material enabling us to arrive at certain conclusions which point to the extraordinary fact that Chinese medicine for some 4500 years of its long drawn-out history remained the same in its conceptions, and was throughout infused with its original tenets of natural philosophy. As Dr. Morse says, after what has clearly been patient and learned investigation of all the available sources, Chinese medicine continued until comparatively recent times to rely on an unassailable cosmic theory, a rigid inelastic system entirely lacking in the quickening influences of a critical open-minded test method. The principles and practices of Chinese medicine are founded on their conception of cosmology. Theories and beliefs over three thousand years old constitute the basis for some of their most important diagnostic and therapeutic customs and practices to-day. In the bulky chronicle of the national medicine written some two years ago by Dr. Kimmin Wong, of Hong-Kong, and Dr. Wu Lien Teh, well known as a director of the Manchurian Plague Prevention Service and of the Chinese Quarantine Service,[2] will be found page after page of detailed information, much of which completes the story, whose headings are clearly set out by Dr. Morse. Until about 1000 B.C. beliefs in demons and mystical attributions to plants was codified into some sort of therapeutic scheme, when there arrived what are known as the Yin Yang principles, and the doctrine of the five elements. Dr. Morse shows that the underlying ethics of Chinese medical practice are still based on the notion of the Yin Yang, and sets out the theories or what may be called the mental mechanism of this scheme of duality. These chapters must be read to understand what follows and to gain some insight into the systems of anatomy and physiology which have prevailed in the country from prehistoric times until quite recently. Indeed, one would gather from Dr. Morse that throughout China generally, as far as the native practitioners are concerned, little advance has yet occurred. But the sadness of this view is relieved by a promise of better things. However local and sporadic the influences of scientific medicine in China may as yet be, there has been a distinct advance in the medicine of China as the result of comparatively recent English and American influences. The medical science of China will not be static for ever in the thraldom of past superstitions, and when modern learning becomes more diffused it would seem impossible that a nation, in whose philosophy so much that is fine and delicate can be observed, should not become prominent in the pursuit of medicine. Dr. Morse has written a valuable guidebook, which Messrs. H. K. Lewis and Co. are now prepared to distribute.

THE SCOPE OF PSYCHOTHERAPY

The Institute of Medical Psychology has published its first annual report[3] since moving into a larger and more suitable building in Malet-place. This report shows a conspicuous increase—about 50 per cent.—in the number of "patient-hours" of treatment given. For several months in the current year the Institute has again had to decline to accept further patients for treatment until it has worked through the list of those already interviewed and waiting. This state of affairs is readily understood by anyone who has charge of a hospital out-patient department where the difficulty in obtaining adequate psychotherapy for the patients who require this is universal. In those hospitals to which a part-time group of psychologists is attached the demands made upon this department are usually excessive, and even when only those patients most likely to benefit are accepted for treatment the waiting-list is long.

This report shows at least one way in which further experience should lead to some relief of the congestion. It shows that out of a total of 270 patients treated, only 58—or less than one-quarter—were regarded by the psychotherapists through whose hands they had passed as being either cured or much improved. When account is taken of the laborious nature of the treatment involved and of the claim that is made for it as being the only method that holds out a reasonable hope of cure or of satisfactory improvement, it is clear from these figures that a very large number of patients have not yielded the results which alone can justify the use of these methods of treatment. This is seen to be true of the majority of obsessional states, paranoid states, and sexual perversions. The low percentage of "cured" also illustrates the fallacy of referring to adults as cases of "early nervous disease"; in the class of patient for whom psychotherapy can claim its best results (the anxiety states) it is well recognised that the problems involved are usually connected with psychological disturbances early in the patient's life, and not at all recent in relation to the appearance of symptoms requiring treatment. In the children's department are to be found the only cases to which the term early can legitimately be applied, and the work of this department, which has been a continuously growing part of the Institute since its foundation as the Tavistock Clinic, is probably providing the most valuable results.

[3] A copy of this report will be sent to anyone interested by the general secretary of the Institute, Malet-place, London, W.C.1.

An institute which hopes to rank on a par with hospitals providing other forms of treatment must be willing to give as much attention to diagnosis as to treatment, and to recognise that a flair for the sympathetic handling of patients is not always combined in one and the same person with the ability and the experience that are necessary for competent diagnosis. It is possible that a more critical weeding out of cases which experience has shown to be unsuitable would do more towards providing useful results than a mere extension of the facilities for the treatment of a larger number of patients of all types. In the meanwhile the Institute is making an increasingly valuable contribution to the problem of providing treatment for the mentally sick, and is an outstanding example of the success which rewards initiative and zeal even in the face of persistent financial difficulties.

A PRESENTATION TO SIR WILLIAM HODGSON

ON Sunday week, May 13th, on the occasion of his eightieth birthday, medical practitioners in the County Palatine of Chester will present Sir William Hodgson with a dedicatory volume entitled "Fasciculus Castriensis." It is an octavo volume of 300 or more pages, containing a brief biographical note of himself and more than 60 articles on clinical and other medical subjects written by practitioners in the county. There is also a statement of the clinical facilities offered by all the local health authorities in the county. The presentation copy will be bound in blue morocco, and will bear the arms of Cheshire and the badge of Æsculapius, while a few days later the volume, bound in blue cloth, will be distributed to all members of the Cheshire panel and will be then put on sale. Sir William Hodgson is chairman of the local medical and panel committee and of the county council, in which he has always been a champion of the general practitioner's status; he is still a practising member of the profession of which he is so distinguished a member.

A QUESTION OF ADVERTISEMENT

THE aim of the National Eye Service organised by the British Medical Association and the Society of Dispensing Opticians is to offer insured persons and their families, and others with family incomes not over £250 per annum, the chance of a consultation with an ophthalmic specialist of their own choice as an alternative to getting their glasses from a prescribing optician or attending a hospital. In many areas the scheme is now in good working order, but it is found to involve the necessity of a certain amount of advertisement, and has been objected to on that ground. In the Southampton area for instance six ophthalmic surgeons have joined the scheme and are willing to examine and prescribe for their patients either at the clinic or at their own consulting-rooms for the modest fee of half a guinea. An advertisement in the local paper announces the fact of the service having been organised, and a card giving names of the surgeons, with times of their attendances at the clinic, has been sent to all practitioners of the area requesting them to display it in their surgeries. It is felt by some that this amount of advertisement is unethical ("not in the best interest of the medical profession" in the words of one communication we have received); but, it may be asked who suffers from it? The general practitioner does not himself do eye work or if, having special experience, he does desire to do it and is qualified by the records of his attainment, he is free to join the scheme. Ophthalmic surgeons who are not on the list because they do not desire to see patients for half a guinea are not affected. Prescribing opticians may certainly be adversely affected, but the belief that opticians ought not to prescribe the glasses that they provide is a fundamental principle of the scheme. The scheme seems to us well calculated to meet the needs of the public and to offer the ophthalmic surgeon a valuable introduction to private practice.

THE SELENIDE TREATMENT OF CANCER

THE treatment of cancer patients who have been rejected by the surgeon and the radiologist is a very formidable problem. Dr. A. T. Todd is one of the few who have attempted to attack it in a systematic manner.[1] and in order to qualify for his treatment at the Bristol Royal Infirmary "every case has to be guaranteed untreatable and to be free of diagnostic doubt." Todd's working hypothesis is that the body reacts to the presence of a neoplasm by a defensive mechanism of which the macrophages constitute the most important part, and that this defensive mechanism can be stimulated by the intravenous injection of certain colloids in carefully adjusted doses and intervals. The first colloid used was a lead selenide preparation called D4S. Of the cases treated with this remedy, he states that "10 per cent. can be claimed as four-year cures," while 50 per cent. of the cases showed a definite prolongation of life, as a rule with comfort. A further development was the combined use of colloids and radiotherapy. For this purpose two new preparations were introduced: a double colloid of sulphur and selenium called SSe, and a feebly radio-active one made from radium residues and combined with selenium as in the original lead selenide colloid. The second preparation, which is called R.A.S., is but very feebly radio-active, and Todd has convinced himself by experiments on animals that its injection is without danger, no harm being apparent even after a long interval. The manufacture of these colloids has been entrusted to British Drug Houses Limited.

In applying the remedies the general aim is to produce an ionisation of the injected selenium colloid. The treatment begins with an injection of the sulphur-selenium followed by irradiation 48 hours later with X rays. This procedure is repeated weekly for about two months, the doses of the colloid and of the X rays being adjusted as as to produce a reaction. Next comes a course in which the two colloids SSe and R.A.S. alternate with one another, one injection being given each week; the feebly radio-active R.A.S. is supposed to produce ionisation of the selenium colloid. If the tumour reacts to this treatment this course of alternation of colloids is continued; if not, a second course of ionisation with X rays is applied three months later. The results Dr. Todd tabulates in two groups. The first comprises 93 cases treated from May, 1931, to September, 1932, and 15 of these are described as "apparent cures;" 10 of these patients are alive more than a year after the beginning of treatment. In addition there are 5 patients still under treatment and 2 of these are alive two and a half years and four years after the treatment commenced. The second more recent group of 62 cases has been treated since September, 1932; and here the results, as Todd himself says, are harder to assess. It contains 3 cases discharged as apparently cured and 9 cases still under treatment but doing well.

---

[1] Brit. Jour. Surg., April, 1934, p. 519.

All this material is of course open to the obvious criticism that the time is too short to speak of a cure, or even of an "apparent cure"; and it is perhaps unfortunate that Todd should use the latter expression in speaking of his successful cases. But in any other of the diseases which are always fatal in their advanced stages, a form of treatment which in a certain proportion of cases will prolong life, remove pain and discomfort, and restore the patient for a long time to normal life would be thought a considerable achievement. Many of those who have seen the patients in Bristol are satisfied that, considering their hopeless state when they came under treatment, the results are remarkable. Dr. Todd may claim to have shown that cancer even in its most advanced stage is still sometimes amenable to successful treatment—in the sense in which that word is used for other diseases and provided that such treatment is applied with skill and devotion.

AMIDOPYRIN AND AGRANULOCYTOSIS

A FORTNIGHT ago we commented on the possible rôle of amidopyrin and the barbiturates in the causation of agranulocytosis. A further group of papers has since come to our notice which support the suggestion that these drugs are sometimes responsible for the condition. Randall[1] describes the case of a woman, aged 25, who developed acute and alarming leucopenia after the use of amidopyrin and barbiturates for simple headache. Hoffman and Butt[2] found that a feature common to 13 out of 14 cases of agranulocytosis was the use of amidopyrin either alone or in conjunction with a barbiturate; they also claim to have produced agranulocytosis in rabbits by the administration of amidopyrin alone. Lastly, Holten, Nielsen, and Transbol[3] in Denmark record a similar relationship between the use of amidopyrin and attacks of agranulocytosis. They describe six cases in which women developed typical agranulocytosis, while in hospital for some other condition, after treatment with amidopyrin, and they believe that agranulocytosis may really be a new disease dating from the introduction of the barbiturates and amidopyrin into therapeutics. During the period 1916–20 an analysis of 34,417 patients treated in a fever hospital in Stockholm shows no death attributable to agranulocytosis; during 1920–25 there were possibly five deaths from this cause, while between 1926 and 1931 as many as 26 cases were recorded. Dr. Holten and his colleagues again lay stress on the fact that there must be certain contributory factors such as personal idiosyncrasy, since in many cases long-continued use of the drugs in question does no harm. It would perhaps be wise, however, in view of the rapidly growing body of evidence that incriminates amidopyrin, not to give this drug unless the leucocyte count is controlled by frequent blood examinations.

THE BRITISH ASSOCIATION

THE annual meeting of the British Association for the Advancement of Science is to be held in Aberdeen from Sept. 5th to 12th. It is the third time that the Association has met there. In 1859 the Prince Consort presided and gave the inaugural address. In 1885 Sir Lyon Playfair was president. This year Sir William Hardy was to have presided, and when he died in January Sir James Jeans was appointed to take his place. His presidential address on Sept. 5th is entitled "The New World-Picture of Modern Physics." One of the evening discourses will be a memorial lecture for Sir William Hardy dealing with the preservation of foodstuffs; the other will be given by Prof. W. L. Bragg on the exploration of the mineral world by X rays. It is hoped to arrange an evening symposium on the general relation between science and the community. Many of the presidential addresses will bear on matters related to medicine. In the section of physiology Prof. H. E. Roaf will speak on colour vision; in the section of psychology Dr. Shepherd Dawson will take psychology and social problems for his subject; in the section of anthropology Capt. T. A. Joyce will tell of the origin and use of yerba maté, and in the section of zoology Dr. E. S. Russell will give an address on the study of behaviour. Other sectional addresses deal with physical methods in chemistry, the future of railway transport, sources of cheap electric power, and rural industry.

Aberdeen offers many attractions to the student. It is the centre of a great agricultural district and of an important fishing industry, while paper-making, granite working, and other industries are well established. Cultural and commercial interests in the city are, it is said, so happily balanced as to justify its ancient motto "Bon Accord." The Rowett Research Institute is easily reached. Preceding the meeting is an international geological excursion ending at Edinburgh on Sept. 3rd, when the Geological Society of Edinburgh celebrates its centenary. The detailed programme will not be issued until August, but those who intend to be present should notify the secretary of the British Association, Burlington House, London, W.1.

WE offer cordial congratulations to Dr. Helen Mackay, whose work on iron and other deficiencies in infancy and childhood is familiar to our readers, on being the first woman elected F.R.C.P. Lond.

NATIONAL INSTITUTE OF INDUSTRIAL PSYCHOLOGY.—Two public lectures will be given on May 7th and May 14th by Mr. F. C. Bartlett, F.R.S., professor of experimental psychology in the university of Cambridge, on recent researches into the effects of noise on work. Lord Horder will take the chair at the first lecture. Mr. J. W. Cox, D.Sc., research Fellow of the Institute, will lecture on May 28th on recent researches into the nature of manual skill. All the lectures will be given at 5.30 in the London School of Hygiene and Tropical Medicine, Keppel-street, W.C. They have been arranged under the Heath Clark bequest.

PROGNOSIS

A Series of Signed Articles contributed by invitation

V.—PROGNOSIS IN ECZEMA

A CYNIC has said that dermatologists are fortunate in that their patients never die and never get well. While skin disease in fact confers no immortality on its victim, there is the germ of a current belief in this quip. The popular impression that skin disease is exceptional in its resistance to treatment is contrary to the facts. That it is still held by many is partly explained by the nature of the lesion, which is essentially objective and therefore constantly under the view of the patient who is only satisfied when every trace of the eruption has been removed. Further, most forms of skin disease do not threaten life; therefore a person who may submit with fortitude to some considerable medical or surgical disability will be impatient with a disorder which does not greatly disturb his general health. He is worried in eczema by the itching or by the degree of the eruption which sometimes prevents him from following his occupation. His disease is his constant enemy; he resents its presence; he is eager to be rid of it and to be rid of it quickly.

It is therefore not surprising that the patient with eczema desires to be assured that he will be cured and seeks to know when he will be cured. The word "cure" is perhaps unfortunate because it connotes two entirely different things. We can cure syphilis and we can cure scabies because they are parasitic diseases the nature of which is understood. In eczema the eruption is merely a symptom; there are probably few forms of eczema in which the patient cannot be relieved, but in none of them is it possible to foretell what will happen later. The word cure therefore as applied to eczema can be used only in a limited sense.

Infants.—Eczema is met with at all ages. It is a common infantile complaint occurring especially between the second and the eighth month, rarely persisting after the second year. The prognosis in infantile eczema can thus be assessed with some degree of mathematical precision. There are other factors which bear upon the outlook: infantile eczema often reacts very favourably to treatment, such as a simple boric-zinc ointment or the more drastic crude coal-tar paste. Where either remedy proves suitable it is often remarkable how quickly even severe forms of the disease subside, and subside completely.

It is very important to differentiate between genuine infantile eczema, of which the prognosis is favourable as has been said, and an allergic eruption classified under the rather clumsy label of the eczema-asthma-prurigo complex with a similar propensity to develop early in life. This spurious eczema often mimics the genuine eruption, but sooner or later indicates its preference for the flexures, the bends of the arms and knees, the neck, and the skin behind the ears. The disease is often hereditary and more than one member of the family may be affected. A family history of asthma or hay-fever is also common, and when the complex is fully developed the skin eruption may alternate with attacks of asthma. It was formerly thought that nothing influenced the course of this chronic and persistent condition, but since the introduction of X ray therapy and intradermal vaccine therapy the prospects of improvement at any rate have become better.

Adults.—In adults eczema may present itself in an acute or in a chronic form. This is the common terminology; it is more useful, however, to speak of extensive and localised or limited eczema, for the acute and chronic phases may both be present at the same time in different regions of the skin. Local patches of eczema, for example on the legs, often respond readily if and when X ray treatment is available and suitable; otherwise they may persist for weeks or in exceptional cases for months. The extensive forms, especially those with an abrupt onset, as a rule pursue a relatively short course, provided the patient is willing to enter a hospital or nursing institution. When they are treated at home the improvement is much slower and much less satisfactory. Where the eruption consists wholly or principally of scattered œdematous papulo-vesicles, progress is slower than where confluent sheets of eczema are present.

With the object of obtaining more exact data I have reviewed a series of 50 cases of eczema, mostly of the severe or extensive type, admitted to my wards at Middlesex Hospital. The duration of in-patient treatment averaged at 5·4 weeks, the longest stay in hospital being 15·5 weeks and the shortest 1 week. This series illustrates the advantages of institutional treatment. Thus two patients with eczema of two years' duration were relieved in 4 and 3 weeks respectively, another of 18 months' duration in 3·5 weeks, and another of 9 months' duration in 4 weeks. It is not implied that the "cure" was complete in any but a very few of the 50 patients cited above. They were nevertheless sufficiently relieved to allow them to resume their occupations while attending the out-patients' department. In private practice rather more is demanded, and it may be estimated that treatment, even if institutional, will be increased to one and a half or even twice as many weeks.

The prognosis therefore in eczema, so far as it applies to any specific attack, is distinctly favourable. For the reason given above it is impossible to foretell what may happen in the future, except that a patient who has once developed eczema is liable to subsequent attacks.

UNCOMMON VARIETIES

Special reference should be made to other forms of eczema which have qualities distinguishing them from the common varieties of the disease.

Eczema of the legs associated with varicose veins is relatively often observed. The special technique originated by Mr. A. Dickson Wright has done a great deal to remove from the category of chronic complaints the forms associated with ulceration. Where the eczema is uncomplicated, however, the use of an elastoplast bandage is often followed by an aggravation of the eruption. Nevertheless it is obvious that the varicose veins, if neglected, continue to exercise a prejudicial effect on the skin condition. Where the veins are suitable for injection, or, failing this, where a supporting crêpe bandage is used, the prospect and degree of improvement is much better.

Dysidrotic eczema, where numerous small vesicles, often with pronounced itching, appear on the fingers, hands, and feet, is a seasonal and recurring eruption observed during the warmer periods of the year. Most of these cases are, in my view, eczematous, but a proportion are due to a ringworm or monilia infection; here the prognosis is much more favourable because the causal organism is susceptible to suitable parasiticides.

Mention should also be made of the *seborrhœic group* of dermatoses which includes dry psoriasiform lesions; sheets of red moist "eczema" of the axillæ, groins, and interdigital cleft and behind the ears; and an acute weeping or œdematous process more commonly found on the scalp, face, neck, and the thin skin over the bends of the joints. Where the condition is eczematised it follows the course of an acute eczema, with, however, a greater tendency to relapse. The form characterised by red moist areas of the groins and axillæ is often extremely rebellious to treatment. In this variety of seborrhœa there is a special predisposition to secondary invasion by staphylococci and streptococci; the resulting boils or impetigo-like lesions when present complicate and interfere with the normal process of treatment, and in this way prolong the duration of the eczema beyond its expected limits.

OCCUPATIONAL ECZEMA

Occupational eczema, in spite of the attention it has received in recent times, continues to be a controversial subject. Certain trades and occupations seem especially to predispose to eczema, or trade dermatitis as it is sometimes called. The eruption, which in form exactly resembles eczema, occurs on the parts of the body exposed to the irritant, and is met with in bakers, grocers, hairdressers, french polishers, and in other groups of workers. Prosser White, who gave special attention to these conditions, stated that if the patient discontinues the occupation for a time, he can safely resume it if the eruption is completely cured, but this is not the opinion generally held. In some cases the eruption clears up immediately contact with the irritant is discontinued, while in others it persists, often for months or years. The question of compensation involves a psychological factor and possibly causes the patient consciously or unconsciously to keep up the eczematous eruption by scratching or in other ways. Patients who suffer from seborrhœic disorders or from hyperidrosis seem especially prone to develop conditions of this sort and in them the prognosis is especially bad. The large question of sensitisation has also to be taken into account. In a person once sensitised his special reaction can be provoked by further contact with the offending agent, and therefore it is unlikely, in spite of the authority quoted above, that he will ever be able to resume an occupation in which the, to him, harmful substance is used.

CONCLUSION

Finally, it may be said that in the great majority, indeed in nearly all, of the different forms of eczema it is possible to cause the eruption to disappear, provided the patient is willing and able to give the necessary time and attention to the form of treatment indicated. The determination to get well which implies the subordination of a measured proportion of the day to the tedious details of treatment may be the determining factor; lack of such self-discipline invariably prejudices the favourable result.

HENRY MACCORMAC, C.B.E., M.D., F.R.C.P.
Physician for Diseases of the Skin, Middlesex Hospital.

WORCESTER MATERNITY DEPARTMENT.—Mrs. Stanley Baldwin recently opened a new maternity department at Worcester Royal Infirmary. It is a compact unit composed of quarters made available by the recent extensions. The old theatre has been converted into a six-bed ward to which a labour ward, a nursery, and other accessories have been attached.

PUBLIC HEALTH

Unhealthy Office Accommodation

WOMEN clerks and secretaries met at Livingstone Hall on April 17th to consider the question of hygienic office accommodation. It will be remembered that the Offices Regulations Bill failed to obtain a second reading in the House of Commons last month. Dr. W. J. O'Donovan, M.P., who addressed the meeting, said it was necessary to convince not only Members of Parliament but also the older clerical workers who had become inured to bad conditions through long experience. In thousands of cases houses which had been built for dwellings had been converted for use as offices although quite unsuitable for the purpose. Mr. Arthur Greenwood, speaking as an ex-Minister of Health, said that the existing Acts were quite inadequate to ensure healthy conditions of office life. Factory workers had secured protection through collective action; unfortunately office workers in the past had been too respectable to agitate. A resolution was carried urging the need of legislation to secure a minimum health standard for office workers.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED APRIL 21ST, 1934

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 3 (last week 3); scarlet fever, 2781; diphtheria, 1060; enteric fever, 22; acute pneumonia (primary or influenzal), 1464; puerperal fever, 66; puerperal pyrexia, 149; cerebro-spinal fever, 34; acute poliomyelitis, 6; acute polio-encephalitis, 2; encephalitis lethargica, 11; continued fever, 1 (Willesden); dysentery, 5; ophthalmia neonatorum, 97. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on April 30th–May 1st was as follows: Small-pox, 11 under treatment [illegible] (last week 11 and 1 respectively); scarlet [illegible] 1654; measles, 3171 (last week 3420); [illegible] puerperal fever, 31 mothers (plus 9 babies); encephalitis lethargica, 259; poliomyelitis, 3; "other diseases," 150. At St. Margaret's Hospital there were 18 babies (plus 7 mothers) with ophthalmia neonatorum.

Deaths.—In 118 great towns, including London, there was no death from small-pox or enteric fever, 119 (54) from measles, 9 (2) from scarlet fever, 48 (9) from whooping-cough, 40 (10) from diphtheria, 37 (13) from diarrhœa and enteritis under two years, and 79 (16) from influenza. *The figures in parentheses* are those for London itself.

Measles is now definitely [illegible] this week there were 9 fatal cases in Liverpool, 7 [illegible] wcastle-on-Tyne and Salford, 4 in [illegible] caused 9 deaths in Liverpool, no m[illegible] at town except London. *Fatal cases of influenza were confined chiefly* to the northern area: Liverpool reported 7 deaths, Manchester 6, Sheffield 3—Birmingham also had 7 deaths. Four fatal cases *of diphtheria occurred* at Manchester, 3 each at Leeds and *Middlesbrough.*

The number of stillbirths notified during the week was 278 (corresponding to a rate of 39 per 1000 total births), including 49 in London.

PROVISIONAL DEATH-RATES FOR 1933

Provisional death-rates per million population for *England and Wales during the year* 1933 are now available as follows:—

	Males.	Females.	Persons.
Respiratory tuberculosis	819	571	690
Other tuberculosis	148	121	134
Cancer	1490	1559	1526

The maternal mortality (provisional) based on deaths primarily classed to puerperal conditions is as follows:—

Puerperal sepsis per 1000 live births 1·83; per 1000 total births, 1·75.

Other accidents and diseases of pregnancy and parturition per 1000 live births, 2·68; per 1000 total births, 2·57.

SPECIAL ARTICLES

THE INCIDENCE OF TUBERCLE BACILLI AND BRUCELLA ABORTUS IN MILK

By E. J. Pullinger, B.V.Sc. S. Africa, M.R.C.V.S., Dipl. Bact. Lond.

RESEARCH INSTITUTE IN ANIMAL PATHOLOGY, ROYAL VETERINARY COLLEGE, LONDON

The main object of this investigation has been to obtain further information of the extent to which milk from tuberculin-tested herds and ordinary non-graded raw milk are contaminated with the organisms of tuberculosis and contagious bovine abortion. The survey of milk-supplies for *Br. abortus* has of recent years received impetus from the suggestion that the consumption of milk contaminated with this organism may produce undulant fever in human beings. The value of "low temperature" or "holder" pasteurisation for destroying bacteria of these groups has also been studied. Milk samples were obtained through the depôts of United Dairies (London) Ltd., through the kind coöperation of Mr. E. B. Anderson, M.Sc. One of the findings has been that, when ordinary raw milk is mixed in large quantities, living tubercle bacilli can be found in it almost constantly. This has stimulated interest in other questions, such as the reasons for such contamination and its extent. In the same connexion, milks from herds in two different parts of the country have been compared. Finally, the work has given an opportunity for studying various technical points connected with the recognition of tubercle bacilli and *Br. abortus* in milk.

The following classes of milk have been examined :—

1. MIXED MILK FROM INDIVIDUAL TUBERCULIN-TESTED HERDS

(*a*) *Certified milk.*—Pint samples, no doubt representing the mixed product from a few cows only, were tested.

(*b*) *Grade A tuberculin-tested milk.*—Samples were taken by trained laboratory personnel, who were daily engaged in such work. Two ounces of milk from each churn, delivered by a producer on the day of sampling, were mixed; and, after shaking, a half pint of the mixture was despatched to the Institute. Separate dippers were used for the milk of each herd.

2. MIXED MILK FROM ORDINARY HERDS

(*a*) *Rail tank milk.*—Pint samples of raw milk were taken from the inlet pipe of the holding chamber of the pasteurising plant, while this was being filled from a 3000-gallon rail tank containing the supplies of a number of producers. A corresponding pasteurised sample was taken from the outlet pipe of the holder 30 to 45 minutes after the collection of the raw sample. Samples from 7 pasteurising depôts were examined.

(*b*) *Raw mixed milk from single farms.*—An examination was made of the milk-supplies from two districts in England—viz., Cheshire (mostly during the spring of 1933) and Somerset (during the winter of 1933–34). Samples were collected in the same way as from Grade A tuberculin-tested herds. One hundred c.cm. amounts were bottled, packed in ice, and despatched to the Institute.

Examination for Tubercle Bacilli

Although much has been written about the presence of tubercle bacilli in market milk, it is not easy to estimate the percentages of the various classes of milk likely to contain this organism. Moreover, the figures available (Table I.) are difficult to evaluate owing to the different techniques used.

The literature referring to the survival of tubercle bacilli after pasteurisation is extensive but contradictory. It is generally agreed that when a modern pasteurising plant of the pre-heating holder type is worked in an efficient manner, tubercle bacilli are killed. When the plant does not work efficiently, however, some tubercle bacilli may survive pasteurisation. Thus, according to a report to the Manchester corporation (1931), 2 per cent. of pasteurised milks were found to contain living tubercle bacilli. J. Smith (1932) found 2·1 per cent. of 187 milks pasteurised by the holder method were contaminated. In the report (1933) of the Medical Research Council it is recorded that tubercle bacilli survived in 2·8 per cent. of 1243 samples after holder-pasteurisation.

Market milk = Ordinary mixed milk not definitely stated to come from one herd. — = Not stated. * Quantity of milk yielding the deposit injected into each guinea-pig. † Licensed T.T. herds. ‡ 1D = c.cm. of deposit.

TECHNIQUE

In deciding upon the inoculum to be used and period of incubation to be allowed, it had to be remembered that two kinds of organisms were being sought. Two guinea-pigs were used for testing each sample of milk, except with milks of classes 2 (*a*) and 2 (*b*). Apart from this, the same technique was used throughout.

After 1 c.cm. of gravity cream had been removed the milk was well mixed and 90 c.cm. were centrifuged at 2000 revolutions per minute for 30 minutes. The deposit was mixed with the gravity cream previously removed and the mixture was inoculated intramuscularly into one guinea-pig, half the amount being injected into each thigh. When two guinea-pigs were used, 2 c.cm. of gravity cream and the deposit from 180 c.cm. of milk were taken. As a rule, guinea-pigs were autopsied six weeks after inoculation, except with milk of class 2 (*b*) when the animals were allowed to survive four weeks only.

The same guinea-pigs were used both for the tuberculosis and *Br. abortus* tests, since, according to Wilson and Nutt (1926), these two infections can develop coincidentally without the one influencing the other. After material had been taken for the *Br. abortus* examination, the organs were examined for tuberculous lesions, and smears were taken for microscopic examination. Cultures were made from the regional lymphatic glands and spleen. The ground-up material was mixed with an equal volume of 20 per cent. antiformin and loopfuls, seeded on plain egg or broth egg slopes, after intervals of five and eight minutes.

The technique in this investigation can be regarded as severe. The relatively low speed of centrifuging is perhaps open to criticism, but it is probably offset by the inclusion of gravity cream in the inoculum. The work was completed before the recent report (1933) of the Medical Research Council was published, according to which living tubercle bacilli in pasteurised milk would have been missed in 35 out of 57 instances if both guinea-pigs had been killed after four weeks. Reliance, however, was placed upon naked-eye appearance of the organs; whereas in this work cultures were made from the glands.

The strains of mycobacterium isolated were not typed, but none of the cultures showed the rapid growth and other features characteristic of avian and saprophytic forms. This bears out the findings of Wilson and Nutt (1926) and Gaiger and Davies (1933 *c*) that the non-pathogenic acid-fast bacilli common in milk products do not produce a condition in guinea-pigs simulating tuberculosis; and it is contrary to the findings of Albiston in Australia (1930), who recorded that 9·3 per cent. of cases of apparent tuberculosis in guinea-pigs, inoculated with milk, are caused by a saprophytic acid-fast bacillus.

TABLE II

Examination of milk from tuberculin-tested herds for tubercle bacilli and Br. abortus

Rail tank pasteurised	,,	63	0	63	0	63
Herd samples	Cheshire.	105	22	88	39	66
,, ,, ...	Somerset.	104	2	102	20	84

From Tables II. and III. it is seen that :—

1. Of 101 samples from 45 producers, only 1 contained living tubercle bacilli. (*a*) *Certified milk.*—Forty-four samples from 19 producers were tested, the milk from 11 of the herds being examined three times at intervals of 4 months. With one doubtful exception all were free from tubercle bacilli. (*b*) *Grade A* (*T.T.*).—Fifty-seven samples from 26 producers were tested, milk from 14 of the herds being examined three times at intervals of 4 months. One sample contained living tubercle bacilli.

2. (*a*) *Rail tank milk.*—All 63 samples examined contained living tubercle bacilli. In the corresponding pasteurised samples these organisms were not detected. (*b*) *Raw mixed milk from single farms.*—Out of 105 samples from Cheshire, 22 (21 per cent.) contained living tubercle bacilli. Of 104 samples from Somerset, only 2 (1·9 per cent.) contained this organism.

TUBERCLE BACILLI IN MILK MIXED IN LARGE QUANTITY

The finding that when ordinary farm milk is mixed in sufficiently large quantity, the whole becomes contaminated with tubercle bacilli in detectable numbers is, perhaps, somewhat surprising. It is usually estimated that not more than about 0·2 per cent. of all cows are affected with tuberculosis of the udder and contamination of milk with tubercle bacilli is therefore probably due to this small proportion. Thus there was the possibility that when large volumes of milk were mixed the chance of finding tubercle bacilli, even by the sensitive guinea-pig test, in 90 c.cm. samples taken at random would disappear. The findings to the contrary might be explained in one or both of two ways: (1) that the percentage of cows excreting tuberculous milk is much higher than is generally believed; (2) that one cow with tuberculous lesions in the udder can contaminate a vast bulk of clean milk. While the second explanation appeared the more probable, an investigation was deemed advisable; but before making it, information was desired as to the extent to which the bulk milk itself was contaminated.

Tubercle bacilli in mixed bulk milk.—Starting with 25 c.cm. of rail tank milk, dilutions were made at 1 in 10, 100, and 1000 with milk from a cow which had passed the tuberculin test. The usual technique was adopted, two guinea-pigs being used for each dilution and for a suitable control of the tubercle-free diluent.

Two samples of tank milk from each of three receiving depôts were examined. In one case the undiluted milk alone was positive; in four instances the milk was still infective in the tenfold dilution; and in the remaining instances as far as the hundredfold dilution.

Extent to which milk from tuberculous udders is infective.—Osterman (1908) found that milk from a tuberculous udder could be diluted 50,000 times and still be infective.

Thanks to the kindness of Mr. D. S. Rabagliati, chief veterinary inspector for the West Riding, milk samples were received from 3 tuberculous udders. These were diluted at 1 in 100, 10,000, and 1 million with tubercle-free milk. In one instance the mixture was infective to the second dilution. In the second and third experiments the mixture was infective to a dilution of 1 in 1 million.

Examination for Brucella Abortus

Some of the results obtained by previous workers, who examined ordinary milk-supplies for *Br. abortus*, are recorded in Table I.

I am unaware of any important series of samples from tuberculin-tested herds which have been examined for *Br. abortus*, although several authors report having found these organisms in such milk. In establishing the presence of the organism in milk, technical methods are important. Thus, Huddleson, Hasley, and Torrey (1927) and Carpenter and Baker (1927) found that the organisms were most numerous in gravity cream; Fitch and Lubbehusen (1926) considered that sediment was the best inoculum, though they thought it safer to use whole milk as well. Karsten (1932), Pröscholdt (1932), and Stockmayer (1933) advocated the use of whole milk for the cultural isolation of brucella. For guinea-pigs, Karsten and Bischoff (1933) recommended a mixture of gravity cream and sediment.

An incubation period of six weeks in the guinea-pig seemed necessary in view of the findings of J. Smith (1932), who in 246 instances noted 43 where agglutinins began to appear four weeks after inoculation with milk containing *Br. abortus*. Ten instances were also noted where agglutinins disappeared before the eighth week. Sheather

923) always found agglutinins within six weeks of ijecting contaminated milk. Smith used the deposit om 25 c.cm. of milk for each guinea-pig and the tardy ormation of agglutinins and their early disappearance iay have been due to the very small numbers of brucella ioculated. Thus Hagan (1922), using high dilutions of ılture, noted the appearance of agglutinins as early as ie second week.

TECHNIQUE

In testing for *Br. abortus*, two methods were used—iz., guinea-pig inoculation and agglutination test of the hey.

(1) At autopsy the spleen was first removed for cultural xamination and heart blood was then taken for an gglutination test. The tissue was ground up in 0·5 c.cm. f broth, and the suspension seeded on a plate of 5 per cent. iorse serum agar or 5 per cent. potato extract agar which ras incubated at 37° C. in a 10 per cent. CO_2 atmosphere. Plates showing no growth after three days were reincubated or four more days. Colonies resembling those of brucella vere tested with specific agglutinating serum. Guinea-pig era were tested with *Br. abortus* suspension (Strain 45), qual in density to Brown's $BaSO_4$ tube No. 5, in dilutions rom 1 in 10 to 1 in 10,240. With milks from non-graded ierds reliance was placed entirely upon agglutination ests of guinea-pig sera.

(2) Milk whey was prepared by the rennet method and ested for agglutinins in dilutions from 1 in 10 to 1 in 640.

From Tables II. and III. it will be seen that :—

1. Of 101 milk samples from 45 tuberculin-tested herds, 70 were positive. (*a*) *Certified milk.*—Of 44 samples, 28 were positive (24 by the guinea-pig test and 4 by agglutination test of milk whey). (*b*) *Grade A* (*T.T.*).—Of 57 samples, 42 were positive (40 by the guinea-pig test and 2 by agglutination test of milk whey).

2. (*a*) *Rail tank supplies.*—Of 63 samples of raw milk, 33 were shown to contain living brucella by the guinea-pig test, whilst in 20 others the whey contained agglutinins for these organisms. There were thus 53 positive samples. The pasteurised samples were apparently free from living brucella. (*b*) *Ordinary raw mixed milk from single farms.*—Of 105 samples from Cheshire 39 (37 per cent.) contained living *Br. abortus*, while of 104 samples from Somerset 20 (19·2 per cent.) were positive.

OBSERVATIONS ON THE TESTING OF MILK FOR BR. ABORTUS

During the investigation an opportunity was taken to obtain information on the following points: (1) the relative values of the guinea-pig and whey agglutination tests; (2) the advantage of using two guinea-pigs for each sample; (3) serum agglutinin titres in inoculated guinea-pigs; (4) diagnosis of the disease in guinea-pigs by cultural and serological methods.

TABLE IV

Comparison of guinea-pig and whey agglutination tests

Class of milk.	Samples.	Whey +. G.P. +.	Whey −. G.P. +.	Whey +. G.P. −.
Graded ..	70	47	17	6
Ordinary ..	47	19	8	20
Total ..	117	66	25	26

G.P. = guinea-pig.

(1) Pröscholdt (1932) recorded that in 16·4 per cent. of 4911 instances the whey agglutination test was positive and the inoculation test negative. In the present investigation, out of 117 instances both tests were positive 66 times, the guinea-pig was positive and the whey negative 25 times, and the guinea-pig negative and the whey positive 26 times (Table IV.).

It is seen that with rail tank milks the inoculation test failed, in nearly half the cases, to reveal *Br. abortus*, although this organism was certainly present. On the other hand, with the better-class milk the inoculation test was more sensitive than the whey test.

(2) The use of two guinea-pigs for each sample is intended, (*a*) to reduce the losses from premature deaths, and (*b*) to decrease errors due to failure of guinea-pigs to become infected owing to the small numbers of *Br. abortus* in the sample, or owing to individual guinea-pigs being abnormally resistant to brucella.

(*a*) The proportion of premature deaths amongst guinea-pigs inoculated with the various classes of milk is shown in Table V. The mortality differences between the graded and rail tank classes are not significant and may be due to chance alone. The numbers of raw and pasteurised samples compared were not large enough to furnish definite conclusions; but it is quite likely that if larger numbers had been available the differences would have been significant. No significant difference in mortality following the inoculation of herd samples collected during warm or cold weather was noted.

TABLE V

Premature Deaths of Test Animals

Class of milk inoculated.	Total used. G.P.'s.	Number lost through intercurrent infections.	Percentage losses.
Raw graded	184	12	6·5
Raw rail tank	78	9	11·5
Pasteurised rail tank ..	78	2	2·6
Herd samples	200	17	8·5

(*b*) Gaiger and Davies (1933 *b*) found brucella infection in a single guinea-pig in 35 out of 87 cases where the animals had survived the full time allotted. J. Smith (1932) killed the first guinea-pig after an incubation period of four weeks and the second after an incubation period of eight weeks, and found in 63 out of 246 cases infection in one guinea-pig alone. In my series out of 66 instances in which two inoculated animals survived the full time, there were eight where a single animal became infected. The use of two guinea-pigs is therefore desirable.

(3) A total of 123 guinea-pigs inoculated with milk containing *Br. abortus* developed agglutinins as follows :—

Serum titres.	1 : 10	1 : 20	1 : 40	1 : 80	>1 : 80
No. of G.P.'s.	2	2	15	11	93

It may be noted that the organism was isolated culturally from both guinea-pigs with titres of 1 in 10. This finding, together with the evidence in the literature dealing with the absence of normal agglutinins for *Br. abortus* in the guinea-pig, supports the view that a titre of 1 in 10 indicates infection. The titres can be classified according to the class of milk noculated.

Class of milk.	No. of G.P.'s.	Serum titres	
		1 : 10–1 : 80	over 1 : 80
Graded	117	18	99
Ordinary	34	15	19

Blood-sera from nine guinea-pigs, which showed infection following inoculation with Grade A (T.T.) milk, were taken at weekly intervals to find the earliest time at which agglutinins would develop. The result showed that in four guinea-pigs agglutinins were present by the fourteenth day and in the remaining five by the twenty-first day. Agglutinins persisted in all animals to the forty-second day and in the six surviving pigs to the sixty-third day.

(4) To compare the relative values of the blood agglutination test and of culture of guinea-pig tissues for diagnosis, the results should be classified, as follows, according to the grade of milk.

Class of milk.	No. of G.P.'s.	Agg. +. Culture +.	Agg. +. Culture −.	Agg. −. Culture +.
Graded ..	128	112	12	4
Ordinary ..	40	11	26	3

Agg. = agglutination.

It will be seen that in 7 (4·2 per cent.) of 168 cases, cultural methods revealed infection, although there was no appreciable formation of agglutinins. This agrees fairly closely with J. Smith (1932), who found 5 (4 per cent.) out of 123 guinea-pigs, and Gaiger and Davies (1933 *b*) 1 (2·4 per cent.) out of 41 positive by culture but not by the agglutination test. The value of conducting a test of the blood-serum is particularly evident in the case of milks of higher bacterial count.

General Discussion

It has now become an established fact that when milk is bulked in large quantities the whole is contaminated with tubercle bacilli. This is evidently due to the fact that the number of tubercle bacilli excreted in the milk of a single cow is very high. From the point of view of safety this is not of great consequence if the milk is pasteurised, as is the case, for instance, with 95 per cent. of London milk. This work has again clearly demonstrated the efficiency of holder pasteurisation, so that the presence of living tubercle bacilli in pasteurised milk must indicate inefficient heat treatment, or even possibly the addition of raw milk.

The differences in the percentages of tubercle bacilli and *Br. abortus* in milk samples from Cheshire and from Somerset suggests that the number of cows suffering from udder tuberculosis and contagious abortion is relatively higher in Cheshire. Thus according to data by Messer (1932), in 1928 the cow population per 1000 acres was 235 in Cheshire and 138 in Somerset. The herds may therefore be larger in the former county, and the larger the herd the greater is the chance of its containing animals excreting tubercle bacilli and *Br. abortus*. The assumption that herds are larger in Cheshire receives support from the data regarding the quantities of milk supplied by the producers on the day of sampling; thus, for Cheshire, the average daily supply was 56 gallons per herd compared with 21 for Somerset. Another point is that of the 24 herds producing tubercle-contaminated milk, 19 were supplying a gallonage above the average for their district. On the other hand, it is possible that the incidence of these diseases is really higher in Cheshire, since the denser the population the greater the chance of the disease spreading, especially where owing to the climatic conditions it is the custom to house stock for relatively long periods.

Taken at their face value, the figures for milk samples from tuberculin-tested herds suggest that the proportion of tuberculous contamination was as high as in the ordinary milk-supplies from Somerset. This, however, cannot be accepted as the case. The examination of the tuberculin-tested herds was far more exacting. Thus, out of 45 tuberculin-tested herds 25 were examined three times at intervals of four months, whilst six were examined twice and were always found to be uncontaminated, whereas the herds from Somerset were examined once only.

The fact that undulant fever in man is frequently due to the consumption of milk containing *Br. abortus* is now well established. Whilst there are a number of figures available as to the presence of this organism in market milk, no extensive examination of milk from officially tuberculin-tested herds has so far been reported.

The figure (70 per cent.) found for milk from tuberculin-tested herds is much higher than any previously reported for ordinary milk, but this cannot be held to imply that the incidence of contagious abortion is greater in tuberculin-tested herds. It would appear that the quality of the milk under test has not been given the attention it deserves, since the detection of *Br. abortus* in mixed milk presents certain difficulties. It seems that the apparent higher incidence of *Br. abortus* in milk from clean herds is due to its lower content of saprophytic bacteria. It must be accepted, for instance, that every rail tank sample in the series contained these organisms and yet they could only be isolated from half the number of tanks. Fortunately in the case of high count milk containing *Br. abortus*, direct agglutination tests of the whey are of value for diagnosis. The titre accepted as positive in this work was 1 in 10, as in the case of blood-sera from inoculated guinea-pigs. Karsten (1932) and Klimmer (1932) took a whey titre of 1 in 20 in mixed milk as evidence of contamination, but they do not give details of the density of the bacterial suspensions used.

The reason why this organism cannot be easily isolated from milk of high bacterial count is for the moment a matter for speculation. It may be that *Br. abortus* is killed by the acids produced by saprophytic bacteria; but this does not seem to be the explanation, since guinea-pigs inoculated with such milk sometimes showed high specific agglutinin titres, although *Br. abortus* could not be isolated from their tissues. *It is more probable that tissue reactions* set up in the guinea-pig by the inoculation of large numbers of saprophytes may cause premature death of small numbers of *Br. abortus* inoculated. This is supported by the observation that the specific agglutinin titre of blood of guinea-pigs inoculated *with dirty milk is usually lower than that of* guinea-pigs inoculated with clean milk.

Summary and Conclusions

1. Out of 101 samples of milk from 45 tuberculin-tested herds, 1 contained tubercle bacilli and 70 *Br. abortus*. With most herds three examinations were carried out at four-monthly intervals.

2. Samples from 63 3000-gallon rail tanks were examined; all were contaminated with living tubercle bacilli and 53 with *Br. abortus*. In the corresponding milk samples after low temperature pasteurisation neither organism had survived.

3. Samples of raw rail tank milk had to be diluted from 10 to 1000 times before tuberculous infectivity for guinea-pigs was lost.

4. Samples of udder milk from cows with tuberculous mastitis could be diluted one million times, with clean milk, without their infectivity for the guinea-pig being destroyed. This explains why rail

tank milk is almost always contaminated with tubercle bacilli.

5. Of milk samples from 105 non-tuberculin-tested herds in Cheshire 22 contained tubercle bacilli and 39 *Br. abortus*. Of 104 samples from similar herds in Somerset 2 contained tubercle bacilli and 20 *Br. abortus*. The significance of these figures is discussed.

6. Premature deaths amongst guinea-pigs inoculated with milk ranged between 6 and 12 per cent., depending on the class of milk under test. Hence, the use of duplicate animals is desirable.

7. Specific agglutinins for *Br. abortus* may appear in the blood of guinea-pigs two to three weeks after inoculation of infected milk and a titre as low as 1 in 10 may be accepted as evidence of infection. Isolation of *Br. abortus* from guinea-pigs, whilst theoretically the more convincing proof of infection, presents technical difficulties, which may render the method less reliable than the demonstration of specific agglutinins.

8. Contamination of clean milk with *Br. abortus* can generally be demonstrated without difficulty by culture from the guinea-pig, or by the demonstration of agglutinins. It is often difficult to demonstrate contamination of dirty milk by the guinea-pig test and in such cases direct agglutination tests of the whey may be used.

9. This work emphasises the need for an extensive campaign for the eradication of tuberculosis and contagious abortion. Eradication schemes must of necessity proceed slowly, and as an immediate palliative efficient pasteurisation of milk can be relied upon to destroy pathogenic organisms found in milk.

I wish to thank Dr. F. C. Minett for advice and criticism during the course of this work. I am also indebted to the directors of the United Dairies Limited for their interest and financial support.

ROYAL WEST SUSSEX HOSPITAL.—During the past ten years the annual deficit of this hospital has averaged £1581 and in 1933 it was £2962. At the annual meeting held at Chichester on April 3rd, it was decided to raise a loan of £6000 from the bank. A resolution was passed abolishing in-patients and out-patients' letters. The income for the year was £12,932, and the expenditure showed an increase of £2800, of which £1100 was non-recurring.

AUSTRALASIA

(FROM OUR OWN CORRESPONDENT)

SYMPATHETIC RAMISECTION

FOLLOWING the report published in THE LANCET of July 19th, 1930, on the value of ramisection in the treatment of spastic paralysis, an editorial appeared in the *Medical Journal of Australia* suggesting that the matter should be further investigated in Australia. The Royal Australasian College of Surgeons, adopting this suggestion, appointed a subcommittee in Melbourne to make an investigation and appointed as its members: A. E. Coates, J. B. Colquhoun, R. M. Downes, C. W. B. Littlejohn, Fay Maclure, Dr. H. F. Maudsley, Sir Richard Stawell, H. Douglas Stephens, Dr. O. W. Tiegs (coöpted), H. C. Trumble, and Prof. F. Wood-Jones. Dr. Coates acted as secretary and Prof. Wood-Jones as chairman.

This committee have now issued their report (Med. Jour. Australia, March 17th, 1934, p. 384). They considered the anatomical and physiological evidence for the existence of a sympathetic supply to striated muscle, reviewed the experiments of Hunter and Royle, and examined the clinical evidence afforded by cases in which ramisection had been done. They have come to the conclusion that there is no definite evidence of a dual innervation of striated muscle—indeed there is much to the contrary—or of the control of muscle tone by the sympathetic nervous system. On the other hand there is evidence of a relation between the sympathetic nervous system and the fatiguability of muscle. Recent work seems to show that there may be a humoral origin for the phenomenon. The absence of any effect of sympathectomy on tetanised muscle seems to exclude this procedure as being of use for the relief of spasm.

The committee were further of the opinion that the operation of sympathetic ramisection is of no permanent value in the treatment of spastic paralysis and that such improvement as may occur can be attributed to psychic effects, together with an appreciation of a warmer limb due to vascular changes. They hold that there is some danger of ascribing to the operation of ramisection certain improvements in the patient's condition which are really due to ancillary measures, such as tenotomies, massage, and rest in bed. They point out in conclusion, however, that the work of Hunter and Royle has not been for nought, since it has been the stimulus of much research, and that special credit is due to Dr. Royle for his elaboration of the operative technique of surgical interference with the sympathetic nerve-supply.

DEATHS FROM CANCER

The statistics issued by the Commonwealth Government for 1932 show that, whilst the death-rate from all other causes has decreased, that from cancer has increased from 74 per 100,000 in 1911 to 105 per 100,000 in 1932. The actual number of deaths from this cause in 1932 was 6875 (3696 males and 3179 females), the largest number occurring in persons between 65 and 75 years of age. Deaths from tuberculosis numbered 3004, compared with 3726 in 1911.

Figures from New South Wales reveal the same general trend of deaths. In 1931 2439 persons died of cancer (972 per million living), the rate being 4 per cent. above the average of the preceding quinquennial period. In 1932 the deaths numbered 2534, equal to a rate of 1001 per million living and 6 per cent. above the average of the preceding quinquennial period. The death-rate from this disease has been steadily increasing in the State and the graph shows an almost straight line from 25 per 100,000 in 1883 to 100 in 1932. During the same period the graph for tuberculosis shows a decline in an almost straight line from 143 to 41 per 100,000.

POST-OPERATIVE TETANUS

In January of last year I referred to certain post-operative deaths from tetanus in New South Wales. The Minister for Health subsequently issued a memorandum to all hospitals recommending the preparation of catgut by the iodine method, instead of the biniodide which was in common use; but in spite of these precautions two further deaths from tetanus following operation have been the subject of coroners' inquiries. In the first of these, tetanus bacilli were found in the wound and, as is usual in such cases, the catgut was held responsible although the chain of evidence was far from complete. In the latest case, however, it appears to be beyond question that the catgut should be absolved from any blame—or at anyrate the catgut used in the most recent operation. The patient died from tetanus on Jan. 3rd, 1934, seven days after a laparotomy. She had had two previous operations on the same site. Microscopical search of various tissues failed to reveal tetanus bacilli, and although some organisms resembling them were found they did not reproduce the disease in guinea-pigs. The whole of the jar of catgut, containing 11 spools, used at the operation was subjected to exhaustive tests. These had all been sterilised with iodine by the Bulloch method and were found to be sterile except that from one spool a bacillus of the *subtilis* type was isolated. This was thought to be an air-borne or accidental contamination. The coroner found that there was no doubt that the catgut used was sterile and that infection occurred apart from the operation. During the hearing attention was drawn to the fact that in the recent cases of post-operative tetanus the operations were all abdominal.

The tests of catgut which have been carried out as a result of these deaths seem to indicate that the biniodide method does not give a sterile gut, and that in this respect the iodine method is preferable. The latter has now been adopted almost generally in New South Wales.

IRELAND

(FROM OUR OWN CORRESPONDENT)

THE TEMPORARY ECONOMIES

IN the Senate last week the Minister for Local Government and Public Health announced his acceptance of the Senate's amendment excluding all medical officers from the provisions of the Local Services (Temporary Economies) Bill. It is to be noted that the amendment saves from deductions not only the dispensary medical officers, but also the whole-time medical officers such as county medical officers of health, county hospital surgeons, and the medical officers of mental hospitals.

DEATH OF DR. BRENDAN MACCARTHY

Dr. Brendan MacCarthy, a former medical inspector of the Local Government Board, Ireland, died at his residence at Ballsbridge, Dublin, last week. Educated at Trinity College, Dublin, whence he received his medical qualifications in 1889, MacCarthy was still a young man when he was appointed a medical inspector under the old Local Government Board. He saw service in many districts of Ireland, and was known as a conscientious, capable, and courteous official. His name came prominently before the public in 1901, when he was associated with Dr. William Smyth, of Burtonport, Co. Donegal, in a heroic action associated with Dr. Smyth's death. An outbreak of typhus fever had occurred on Arranmore Island, which lay in Dr. Smyth's district, although several miles from the mainland. It became necessary to transfer some of the patients from the island to the workhouse hospital at Glenties. The local boatmen had such a dread of the fever that none could be persuaded to give their services. MacCarthy and Smyth themselves manned a boat, carried the patients in their own arms, and rowed the boat to the mainland over a stormy and threatening sea. Smyth contracted typhus and died. The Arnott medal was subsequently presented to Brendan MacCarthy for his share in the incident. He retired from the public service some years ago.

BACTERIOLOGY OF CHRONIC RHEUMATISM

At a meeting of the Ulster Medical Society on April 19th, Sir Thomas Houston read a paper on chronic rheumatism, with special relation to the rôle of enterococci. The president, Prof. W. J. Wilson, occupied the chair, and there was a particularly full attendance of members and fellows. The speaker discussed the various classifications of chronic rheumatism which have been brought forward and suggested that in spite of the variety of the clinical types there may be a basal or specific infecting organism. He drew an analogy with tuberculosis, another disease with protean clinical manifestations. In America, he said, various workers had contributed to the long-held view that streptococci and rheumatism are associated. Several types of organism had been incriminated, but he felt it wrong to suppose that a definite clinical entity could have several causal organisms. Recent studies with the bacteriophage carried out by Sir Thomas Houston had supplied a partial explanation, for in the presence of phage the morphological character of organisms, particularly streptococci, changed.

Turning to the rôle of enterococci, he said that in chronic rheumatism these were often found in septic foci—e.g., in the tonsil or urinary tract. An appreciable number of subjects gave a positive agglutination when their serum was tested with one or other type of enterococci. In some of the more acute forms of rheumatoid arthritis he had cultured enterococci from the joint fluid. A final argument was the sensitiveness of patients suffering from chronic rheumatism to enterococcal vaccines. Sir Thomas discussed the manner in which these organisms may be differentiated from all other streptococci, and produced evidence that their character could be made to change so that they might resemble the *Streptococcus viridans*. Such changes were liable to take place when enterococci were artificially infected with phage.

DUKE OF ATHOLL'S FUND.—The distribution of this fund began last week. The first list of beneficiaries contains the names of 116 hospitals and charities in England, Wales, and Northern Ireland; to Scotland a lump sum of £10,000 has been allotted. The total sum distributed amounted to £45,200. In compiling the list the Duke was advised by Lord Moynihan and Major-General Sir Wilfred Beveridge.

MEDICINE AND THE LAW

An Injured Policeman: Gallantry or Contributory Negligence?

IN a case where a police constable had been injured while stopping runaway horses in a crowded street Mr. Justice Finlay had last week to decide whether in such an emergency the ordinary normal man is likely to be impelled towards altruistic gallantry or towards a selfish inaction. It is prima facie negligence to leave horses and carts unattended in the highway if they afterwards bolt and injure people. The owners of the runaway van, however, taking a somewhat rigid view of the legal position, contended that the constable had been guilty of contributory negligence in what he did: he need not, they said, have put himself in jeopardy; he voluntarily assumed the risk. The constable answered that it was his duty to protect life and property. When he saw the impending danger, he was looking out of the window of the police station and thus was not on traffic regulation duty; he just acted in accordance with his general obligation towards the public, ran into the street, pushed a woman aside into safety, and stopped the runaways. The court observed that, if anyone is negligent, he is responsible for all the natural consequences of such negligence. Was the policeman's brave act a natural consequence of the van-owner's negligence in leaving the horses unattended? Yes, said the judge; if a horse runs away, it is obvious that people may be knocked down and that somebody will try to stop the animal in order to prevent injury to life and limb—"one must have regard not only to the victim but also to the rescuer." Judgment was given for the policeman with costs so that he will not suffer for his courage.

How are people likely to act in emergency? Ten years ago Mr. Justice Swift tried a case where, by the defendants' negligence, glass fell into a shop; a woman sprang forward to help her husband who was working there; she was hurt and it was held that she was entitled to damages against the negligent defendants. But Mr. Justice Finlay was faced last week by a recent decision whereby the Court of Appeal checked the tendency to extend the scope of liability. A dairycart had been left unattended, the horse bolted, and a neighbouring householder descended into his garden to see if his children were safe. Meanwhile the horse and cart had come to a standstill in an adjoining field; the man in charge of the cart had arrived on the scene and was shouting for help to hold the horse. The householder, who said he knew very little about horses, climbed over the fence into the field and went to the aid of the dairyman. The horse reared and knocked him down. The Court of Appeal denied his right to damages. Nobody, said Lord Justice Scrutton, has an absolute duty to run out and stop another person's horse; people must be taken to contemplate the probable consequences of their actions; the probable consequence of trying to stop a horse is that one is likely to be hurt. In last week's case Mr. Justice Finlay managed to distinguish the facts from those before the Court of Appeal. For one thing the policeman had a general duty to protect life and property; for another a runaway horse in a crowded street stimulates reactions different from those set up by a restive horse inside a field.

Scientific Evidence of Identity

Sir Francis Fremantle's question to the Home Secretary last week as to the admissibility of blood tests in affiliation cases elicited official recognition that the evidence would be admissible although any provision for compulsory tests would require legislation. As Sir John Gilmour pointed out, the present difficulty is practical rather than legal; there is the question of the cost of the test falling on the man and also the question of his securing the coöperation of the woman. In recent proceedings in the Chatham police-court, noted in these columns not long ago, the legal representative of the woman demanded the blood test, and in cross-examination obtained a consent from the man, but the magistrates decided the case on other grounds.

There was no serious doubt about the admissibility of the evidence if available. A parallel is afforded by expert evidence in criminal cases to determine whether blood is human blood or not. Juries may be unimpressed by a novel application of the results of scientific research, but at any rate the evidence can be offered. The position in criminal proceedings is dominated in English courts by the general principle that the prosecution must prove its case and that the accused has not to prove his innocence. The prosecution has no inherent authority to experiment with the body of the accused in order to establish a case against him. Even the taking of finger-prints or photographs is restricted by prescribed limitations. Once a man has been convicted, his finger impressions and his photograph and measurements may be compulsorily recorded under the Prison Rules, statutory authority being afforded by the Prevention of Crimes Act, 1871, as extended by Section 8 of the Penal Servitude Act, 1891. But an untried prisoner's finger-prints, photograph, or measurements can be taken in prison only on the order of the governor or upon an application in writing made by a police officer of not lower rank than a superintendent if the prisoner objects. The process is not automatic. If the untried prisoner adheres to his objection and force is required, the application must be confirmed by the Secretary of State or by a justice of the peace. If the untried prisoner is discharged or acquitted by the examining magistrates and has not been previously convicted, the photographs and finger impressions must be forthwith destroyed or handed over to him. The value of photography in identification is illustrated afresh by an Indian case recorded in the *Times* of April 18th. In 1925 a villager fired at the legs of two robbers who decamped. Recently a man in custody confessed to several robberies, including that of 1925, and gave the name of his accomplice, who was wounded in the knee. The accomplice was arrested and denied the accusation. There was no external sign of a wound, but X ray photography revealed five small shots in the knee. This evidence, not perhaps conclusive in itself, turned the scale and he was sentenced, nine years after the offence, to seven years' rigorous imprisonment by the Patna court.

KING GEORGE HOSPITAL, ILFORD.—In 1933 there were 3048 in-patients, a substantial increase, and 24,000 out-patients. The beds available are 142, but the average daily number made up was 148. In 1927 there were only 64 beds, by the end of the present year there will be 200. The average stay was 17·9 days. There was a surplus of income over expenditure of £70. The report claims "not only that the King George Hospital made a fuller use of the beds at its disposal than other comparable hospitals, but that the cost per bed was appreciably below the average." The average weekly cost per in-patient was £3 0*s*. 2*d*., and the average total cost £7 13*s*. 11*d*.

PANEL AND CONTRACT PRACTICE

Sickness Benefit and the R.M.O.

LAST week in the House of Commons Mr. J. S. Crooke, M.P. for Deritend, asked the Minister of Health if he was aware that certain approved societies refused health insurance benefits to members, although certified by their panel doctors, unless and until the applicants had been examined by the regional medical officer; and whether, seeing that this action caused unnecessary hardship, he would take steps to revise the rules of approved societies to ensure that payments of benefit were made before the members were sent to the R.M.O. And the Parliamentary Secretary to the Ministry made the following reply:

> Where an approved society desires to obtain a second medical opinion on the subject of a member's incapacity for work, it is entitled to refer the case to a regional medical officer, and it is the general practice of societies in such cases to pay benefit in respect of any period of certified incapacity up to and including the date on which the member is examined by that officer. The payment is made at as early a date as accords with the society's general administrative arrangements, and the Minister does not think it would be reasonable or practicable to impose on societies an obligation to make the payment in all cases before the date of examination.

This defines the position which arises when an insured person claims to be incapable of following his occupation and consequently claims sickness benefit under the Act. The decision to pay or not to pay benefit rests with the approved society. It has to rely on obtainable evidence. If the insured person has kept his stamps up to date, and is not in any other way under the society's rules disentitled to benefit, then probably the most important piece of evidence the society will have to guide it in deciding whether to pay or not is the doctor's certificate. Societies get to know the relative value of these certificates. After the hundreds of thousands of references, after the inquiries into the certification returns, it is fairly well known in approved society circles whether the certificate of Dr. X is or is not likely to be upheld on appeal. If on reference to the R.M.O. most of his cases are found to be capable of work the insured person who claims sickness benefit on his certificate is suspect at once. Before any payment is made to him—and more especially if the sick visitor reports him to be looking well or able to get about—the society will ask the opinion of the regional medical staff. Under these circumstances it would not be "reasonable or practicable" to insist on prepayment of benefit, for it would be impossible to get the money back if the patient was found not to be incapable of work. He can of course appeal.

Some insured persons get the reputation of making claims which are not likely to be justified; they may be so good at it that a doctor who does not know their record may be deceived into granting a certificate of incapacity. Such a case will be sent to the R.M.O. with a report from the society that this patient on previous occasions has been found capable of work. The R.M.O. has the files before him and acts accordingly. The question of financial hardship does arise, although in London the arrangements are so precise that the R.M.O.'s opinion is obtained within four to five days.

Another point has been raised by the organising assistant medical secretary to the London panel committee as a result of his personal contact with insurance practitioners—viz., that many insured persons fail to present themselves for examination because they do not feel equal to the exertion and inconvenience of a journey to Westminster. The Ministry seem to have realised that there is something in this complaint for they have recently modified the arrangements. Whereas there used to be six or more sets of rooms at Dean Friar-street set aside for examination of referred persons there is now only one, and a new centre has been opened at Charles-square, Hoxton, with two sets of rooms, while a little time ago the Stratford-by-Bow centre was increased from two sets to three. There are of course other centres in the outskirts of London—e.g., at Kilburn, Tottenham, Lewisham, Clapham. The advantage of this arrangement is that patients do not have so far to travel and the railway and bus fares to be refunded are reduced in amount. It would be well for insurance practitioners, when sending in a report about a patient who has difficulty in getting about, to indicate to the divisional officer that such-and-such a centre would be convenient if it could be arranged. Another way of smoothing these difficulties is to give the particular day of the week on which a hospital patient usually attends there.

THE SERVICES

NEW CONDITIONS FOR R.A.M.C. OFFICERS

A Royal Warrant published in a special Army Order on April 27th promulgates new conditions under which the commissions in the R.A.M.C. will in future be granted to qualified medical men. The conditions will give effect to the recommendations in the Report of the Fisher Committee on the Medical Branches of the Defence Services issued last year, so far as they affect the Army. The report was fully dealt with at the time of its issue (v. THE LANCET, 1933, ii., 299 and 1059). Hence entry will be by short service commissions for 5 years, at the end of which time officers will be eligible for a gratuity of £1000, unless selected for permanent commissions. Promotion will be to Captain after 1 year and to Major after 10 years' service, instead of after 3½ years and 12 years respectively. The increments of pay which have hitherto been given in these ranks after 8 and 10 years in the case of Captains and after 15, 18 and 20 years in the case of Majors, will in future be given to Captains after 6 and 8 years and to Majors after 13, 16, and 18 years. The establishment of permanent officers will be maintained at a number which it is calculated will ensure promotion to Lieutenant-Colonel and Colonel after approximately 17 and 25 years' service respectively. In the past, the rank of Lieutenant-Colonel has been attained after about 24 years' service, and that of Colonel after about 29 years' service.

It should be noted that ample professional opportunities exist in the course of the duties of officers of the R. A.M.C., for these comprise not only the medical care of the soldiers but of their wives and families, while officers are encouraged to specialise in selected subjects. A selection of candidates for the service, we are informed, will be made about the middle of next June, and full particulars of the conditions can be obtained either by personal application or by letter addressed to the Assistant Director-General

Army Medical Services, the War Office, London, S.W.1.

ROYAL NAVAL MEDICAL SERVICE

Surg. Lt. C. H. Egan to be Surg. Lt.-Comdr.

The following appointments are made: Surg. Comdr. N. A. H. Barlow to *President* for Royal Tournament. Surg. Lt. D. W. Walker to *Drake*.

ROYAL ARMY MEDICAL CORPS

Maj. C. H. H. Harold to be Bt. Lt.-Col.

RESERVE OF OFFICERS

Lt. W. F. de C. Veale, from Wilts R., Supp. Res. of Off., to be Lt.

Dental Corps.—Lt. G. W. C. Bolster, from Gen. List, to be Lt.

TERRITORIAL ARMY

Col. L. D. Bailey, K.H.P., vacates the appt. of A.D.M.S., 47th (2nd Lond.) Div., on completion of tenure, and Col. P. H. Mitchiner, K.H.S., is appointed to the vacancy.

Lt.-Col. F. R. Harris resigns his commn. and retains his rank, with permission to wear the prescribed uniform.

Capt. P. W. MacLagan, having attained the age limit, retires and retains his rank, with permission to wear the precribed uniform.

A. W. Henderson to be Lt.

Supernumerary for service with the O.T.C.—W. M. Nichols (late Cadet Serjt., Glasgow Univ. Contgt., Sen. Div., O.T.C.) to be Lt. for duty with the Med. Unit of the Glasgow Univ. Contgt., Sen Div., O.T.C.

INDIAN MEDICAL SERVICE

Col. D. P. Goil to be Maj.-Gen.

Lt.-Cols. H. C. Buckley and C. H. Reinhold to be Cols.

Maj. N. S. Jatar to be Lt.-Col.

Lts. F. A. B. Sheppard, M. K. Bryce, and J. L. O'Neill to be Capts.

Lt. (on prob.) H. H. Mahmood to be Capt. (on prob.).

Capts. B. Singh and J. M. Gole relinquish their temporary commns.

ROYAL AIR FORCE

V. D'A. Blackburn and J. A. Crockett are granted short service commissions in the rank of Flying Offr. for three years on the active list.

Flight Lts. F. P. Schofield and G. J. Hanly are promoted to the rank of Squadron Leader.

Flying Offrs. H. J. Melville, J. L. Walsh, and A. H. Osmond are promoted to the rank of Flight Lts.

Flight Lt. M. J. Cahalane relinquishes his temporary commission on completion of duty.

Flight Lt. (Honorary Squadron Leader) E. E. Isaac relinquishes his temporary commission on completion of service.

Dental Branch.—W. V. A. Denney is granted a non-permanent commission in the rank of Flying Offr.

Flying Offr. J. E. Willoughby is promoted to the rank of Flight Lt.

CINERADIOGRAPHY

At a special meeting of Fellows of the Royal Society of Medicine held on May 1st, Dr. **Russell J. Reynolds** gave a demonstration of a practical method of X ray cinematography. The President, Mr. V. **Warren Low**, took the chair.

Dr. Russell Reynolds recalled that in 1897 Dr. John MacIntyre, of Glasgow, had shown the moving bones of living animals. His own first experiments had been made in 1921. Methods, he said, must be simple, expeditious, and inexpensive if they were to come into general use. There were two means of taking rapid serial radiograms: the direct and the indirect. The former being very costly, he had directed his attention to the indirect method, in which an ordinary cinematographic camera was used to take photographs of the shadow cast on a fluorescent screen. The three essential conditions were: a sufficiently brilliant image, cutting off the unwanted X rays from the film and ensuring that the subject was not exposed to an excessive dose. Only recently had technical improvements made it possible to obtain satisfactory records of the viscera. Fortunately the lens itself proved to be sufficient protection against direct rays, and it was only necessary to protect the camera with lead. The patient could be protected by synchronising the working of the X ray tube with the movements of the camera shutter. A total exposure of 16 seconds to one area had been given and repeated, and no ill-effects had been noticed. Dr. Reynolds showed lantern slides of the synchronising apparatus and the general lay-out, and gave details of the technique. The method was simple enough, he said, to be worked in any hospital or consulting room, and the apparatus took up very little room. The film was non-inflammable so that no special fire precautions were necessary. The image could be projected normal-sized or enlarged. It was unnecessary in practice to have a long length of film; a short piece could be made up into a band and run continuously through the projector. In this way cases could be studied at leisure. The exposure need only be long enough to obtain a record of the movements desired; in most cases this could be done on a piece of film a foot or more long in a very few seconds. The resulting negative could be printed off again and again on a length of positive film. The expense of production with a 16 mm. film was small.

Dr. Russell Reynolds considered that the method should prove of immense value in investigating lesions of the lungs and pleuræ, especially after lipoidol injections or artificial pneumothorax. There were obvious advantages, too, in being able to study indefinitely movements in pathological states of the alimentary tract. In orthopædic lesions the range of movement in joints could be observed and progress watched. The permanent records could be used in diagnosis, to watch progress or the effect of treatment, to send to other physicians for information or a second opinion, and for teaching purposes. The value of radiology in elucidating anatomy was well recognised; radio-cinematography would do much to reveal the function of organs, notably the heart.

Dr. Russell Reynolds then took a film on the platform, where apparatus was set out for inspection. The film was developed and shown at the conclusion of the meeting. A series of beautiful human films was demonstrated, showing movements in joints, the process of deglutition, the movements of the stomach and intestines, the action of the heart and aorta, respiratory movements of the diaphragm and ribs, and finally the modified, laboured action of some pathological hearts.

Dr. R. **Janker** (Bonn) said that he had cinematographed small objects only by the direct method, at a rate of 22 exposures a second. He showed lantern slides of his apparatus and technique, and then a series of films. The first was the thoraces of a rabbit and a cat showing respiration and heart action in normal breathing and in single and double pneumothorax. The effects of carbon dioxide were shown, and the pulsation of the bronchi demonstrated by filling them with opaque substance. Some interesting pictures showed opaque injection into the femoral vein, its rapid passage to and through the heart, and the formation of emboli in the lungs. Striking films of gastro-intestinal movements in animals followed.

Both sets of films met with high praise from a critical audience who were obviously impressed with the possibilities of the new technique.

OBITUARY

WILLIAM HENRY WELCH, M.D. Columbia Univ., Sc.D. Camb., F.R.C.P. Edin.

LATE DIRECTOR, JOHNS HOPKINS SCHOOL OF HYGIENE AND PUBLIC HEALTH

THE death is announced of Prof. William Welch, the great pathologist, which occurred on April 30th in the Johns Hopkins Hospital, Baltimore, at the age of 84. His fame was literally world-wide.

WILLIAM HENRY WELCH

From a dry-point portrait by Alfred Hutty

William Henry Welch was born at Norfolk, Connecticut, in 1850 of a remarkable medical lineage, for his father, his grandfather, and his great-grandfather were doctors, while he had four medical uncles. A student of the University of Yale he graduated there in Arts in 1870 with high classical honours, but reverted immediately to the family vocation, and in 1871 began his medical curriculum at the College of Physicians and Surgeons, New York. This he added to by scientific work at Yale, and graduated at the College in 1874, when he became interne at the Bellevue Hospital in New York City. This post he held for over a year, and in 1876 started on a series of post-graduate instruction on the continent. His selection of centres and of great leaders was remarkable. At Strassburg von Recklinghausen, at Leipzig Ludwig, and at Breslau Cohnheim assisted in Welch's acquisition of a wide range of knowledge. In Cohnheim's laboratory he witnessed the early experiments of Robert Koch; he went for some months to Vienna, where Chiari and Hebra added to his accumulating store; and before returning to New York in 1878 he made a short stay in London in order to attend Lister's lectures. More remarkable than the young man's ambition and assiduity must seem his power—soon to be proved—of sifting and assimilating such varied and often critical information, retaining both the spirit and the essentials.

On his return to New York it is not surprising that there was competition for his services, and within the next eight years he was offered teaching positions at the College of Physicians and Surgeons of New York (Columbia University), and at the Bellevue. From his first-hand experiences he was able to take, or rather was given, an absolute leadership in settling the share which bacteriological theory and experiment, pathology and pathological anatomy should play both in the routine education of the medical student and in the general development of clinical medicine. A few years later began his long association with the Johns Hopkins University of Baltimore. The story runs that the authorities of the new university inquired from European leaders of medicine for a man qualified to guide the students of Baltimore in modern pathology, when the reply was received that the ideal man for the task was already in their own country and at their doors. As a result Welch was appointed at the age of 34 the first professor of pathology in the university and pathologist to the Johns Hopkins Hospital. His next step was characteristic, for he immediately returned to Europe further to study bacteriology under Koch in Berlin, to work with Pettenkofer in Munich, and with Flügge in Göttingen. He was absent for a year, but the time was well spent, for immediately in the new medical school developments were made in the teaching of pathology under which all the various branches of the subject were correlated with the well-known results. And he worked in a wonderful milieu, for three of the staff of the hospital at the time were William Osler, W. S. Halsted and H. A. Kelly. When the Johns Hopkins medical school was officially opened in 1893 Welch was appointed dean, and gathered round him an institute of experimental medicine of a character unknown in America before—the names of the post-graduate students make medical history. He held the post for five years and discharged its duties while conducting his own investigations, supervising the collection of pathological specimens for a museum, and lecturing in learned and fascinating; way for his teachings were always suggestive of new undertakings, so that those who studied under him caught the zest of his personality. His famous pupils as much as his own work established him as a world influence; and many of them became the leaders in campaigns of all sorts for social and hygienic reform, for Welch was a great judge of character and knew extraordinarily well the qualities of those who served with him.

Welch's career was one of public service. He was president of the Maryland State Board of Health for a quarter of a century, and modern sanitary conditions in Baltimore are the result of his work. In the legislature he was able to promote the enactment of many measures bearing on public health, while he took a prominent part in the formation of the Yellow Fever Commission of the United States Army, upon whose labours followed the comprehension and prevention of yellow fever. During the war, while acting as director of the Johns Hopkins School of Hygiene and Public Health, he discharged medical duties in connexion with the United States Army Reserve, with the final rank of brigadier-general. He resigned his post as director of the School of Hygiene in 1926, but although aged 76, he knew that he had it in him to further promote the cause of medical science. He accepted the position of professor of the history of medicine in the University and—characteristically—immediately came to Europe to study similar institutes and to buy books bearing on the enormous subject. On his return to Baltimore the university founded what is now known as the William H. Welch Medical Library.

Consultation of the Surgeon-General's Catalogue will reveal an extraordinary list of writings under Welch's name. Most were short—almost pamphlets, all were worth while, and many were reissued more than once and bound up as series. His principal contribution to our learning is the treatise on the general bacteriology of surgical infections. It was not, however, as writer, but as original worker and fine exponent of the work of others that he won his fame. And how far-ranging that was is shown by his possession of a long list of honorary doctorates, his nomination to a similarly long series of presidencies of all sorts, including the medical board of the Rockefeller Foundation, and his decorations received from the governments of many foreign countries.

Welch, through frequent visits to Europe, was well known to many English medical men, who will recall his quietly learned conversation, his hospitality, and his courtesy. He could never be mistaken for other than a great man, and he never posed as such.

He was unmarried.

THOMAS RICHARD LLEWELLYN, L.R.C.P. Lond., M.R.C.S.

THE death occurred on April 20th of Dr. Thomas Richard Llewellyn at his house in Penarth. He received his medical education at University College, London, and for a considerable period practised as a colliery medical officer. He was surgeon to Porth Cottage Hospital, Glamorganshire, and acquired an extensive medical practice in the Rhondda Valley, from which he retired to join the Regional Medical Service on its inception in 1920.

We have received from Dr. Llewelyn Williams, medical member of the Welsh Board of Health, the following tribute to Dr. T. R. Llewellyn, whose death constitutes a genuine loss to insurance medical practice in South Wales: "Dr. Llewellyn acted as regional medical officer for East Glamorgan and Monmouthshire. He was a man of strong personality and his high ideals of medical service called for the best from insurance practitioners who practised in his region. He was always frank and straightforward and had a somewhat courtly manner; no one could take liberties with Dr. Llewellyn, but those who tried to do their best found in him a good friend. His wide clinical experience in a large colliery practice before and after the passing of the National Insurance Act enabled him to perform his duties as medical referee with great satisfaction to approved societies and insurance medical practitioners. Much of the improvement in the clinical aspect of insurance practice is due to his efforts. The Welsh Board of Health have lost a loyal and efficient officer and his medical colleagues a true and faithful friend."

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Lotteries and Hospital Finance

IN the House of Lords on April 26th, the Marquess of LONDONDERRY, in moving the second reading of the Betting and Lotteries Bill, said the Government had not approached this question from the moral point of view. Private morals were a matter for the individual conscience and the improvement of individual behaviour must be left to the influences of religion and education. Their sole concern had been with the social effects of gambling, and they had based their proposals solely on a consideration of the evil social consequences which excessive and continuous gambling had been shown by experience to entail. Under the existing law all lotteries were unlawful, unless expressly authorised by Act of Parliament.

The law made no differentiation between large and small lotteries, or between public and private lotteries; and it was immaterial whether a lottery be for charity or for private gain. If the law were strictly enforced effective steps could be taken to suppress at any rate those lotteries which were promoted in this country. But the law had long been recognised to be too drastic in its provisions so far as concerned certain innocuous forms of lottery; and an administrative practice had grown up in England and Wales, and had been in force for many years, under which the police did not set the criminal law in motion against private lotteries confined to members of a genuine club or society or against such small public lotteries as raffles at bazaars and the like. As the Royal Commission pointed out, a new situation had arisen from the sale in this country of tickets in lotteries promoted abroad, notably the Irish Hospitals Trust sweepstakes. Ever since the introduction of the Irish sweepstakes there had been an agitation in this country for the legalisation of large lotteries for charitable and other objects, but, so far, Parliament had definitely set its face against any relaxation of the existing law, and had maintained the prohibition of all forms of lotteries, whether promoted for charitable or other objects. In 1918, long before the Irish sweepstakes, a second reading was refused in the House of Commons to a Bill (the Lotteries (War Charities) Bill, 1918), which had passed through their Lordships' House, and the object of which was to allow the governing body of a registered war charity, with the consent of the police, to raise money by lotteries.

The question of lotteries, said Lord LONDONDERRY, came up for discussion again in May, 1931, when leave to bring in a Bill to authorise the raising of money by means of lotteries for the support of hospitals was refused in the House of Commons. In 1932 a Bill making it lawful for the governing body or trustees of any charity, within the meaning of the Charitable Trusts Acts, to hold a lottery, with the approval of the Secretary of State, to raise money for charitable, philanthropic, scientific, or artistic purposes, or for carrying out any public improvement or other public object, obtained a first reading in the House of Commons, but made no further progress. The Royal Commission, in their final report, reached the conclusion that a relaxation of the existing prohibition of large lotteries was undesirable and not called for. The Government, having also given independent consideration to the question and having studied the views expressed in the House of Lords on Nov. 30th last (see THE LANCET, 1933, ii., 1346), were in agreement that large scale lotteries, whether promoted by the State, for the direct benefit of the Exchequer, or by a statutory Board, for charitable objects, or by individual charities under a system of permits, were socially undesirable.

As regarded lotteries for charitable purposes, it might be questioned, as the Royal Commission pointed out, whether in the long run voluntary hospitals in this country would benefit by participation in the proceeds of lotteries, and speaking for himself, as president of two hospitals, he was quite convinced that the adoption of the system of public lotteries for the support of our hospitals would be disastrous.

The total receipts of 1014 British hospitals for the year 1930 was over £15,500,000. It was clear that, unless the total subscriptions to lotteries amounted to a very large figure, the proceeds would not be a very material factor in hospital finance. But, quite apart from the purely financial consideration, he was of the opinion that it would be calamitous to this country if, by encouraging hospitals to derive their finances from the proceeds of lotteries, hospitals were to lose that element of personal service and personal interest which the present voluntary system achieved.

If the promotion of large lotteries in this country was to be prohibited, the prohibition of the sale of foreign lottery tickets was a necessary corollary.

The law against lotteries was over 100 years old. In form it was largely archaic, and experience had shown that one of its greatest defects was that it did nothing to stop one essential factor in the success of the Irish sweepstakes—namely, press publicity. Clause 19 of the Bill maintained and re-enacted the general prohibition of lotteries other than certain small schemes. It would continue to be an offence to print, publish, or sell, or distribute, or advertise for sale any tickets or chances in a lottery. The Bill prohibited absolutely the publication of matter descriptive of the drawing, or intended drawing, of any lottery, or any list (whether complete or not) of prize-winners or winning tickets in the lottery. It prohibited the publication of any other matter relating to any lottery which was calculated to act as an inducement to persons to participate in that lottery or in other lotteries. It made it an offence to bring into, or to invite any person to send into, this country any tickets or advertisements of a lottery for the purpose of sale or distribution. It prohibited the sending abroad, by agents in this country, of counterfoils or money derived from the sale in this country of foreign lottery tickets.

The Bill did not seek to make it an offence for an individual to purchase a ticket in a lottery. That was in accordance with the general principle, which they had adopted, that the law was aimed at the exploitation of the gambling propensity of the public, and did not seek to punish the individual citizen who made use of facilities for gambling provided by others.

Water-supplies Bill

In the House of Commons on April 30th the Water Supplies (Exceptional Shortage Orders) Bill was read a third time. Sir Hilton Young, in moving the third reading, said that although there had been a welcome change, it had not been so substantial as to make the measure unnecessary. There had not been more than normal rains, and abnormal rains would be necessary to relieve the Government from the necessity for the emergency measures. He had received returns from nine of the places where the difficulties were greatest, and in only one place had there been such a large increase as to put a new face on the situation. The Government still looked to the country as a whole for its coöperation in protecting itself against the evil consequences of the drought.

Health and Welfare in Shops

On April 30th the Shops Bill, which had already passed through the House of Lords, was read a second time and committed to a standing committee.

Plymouth Hospital Bill

In the House of Lords on May 1st, the South Devon and East Cornwall Hospital, Plymouth, Royal Albert Hospital, Devonport, and Central Hospital, Plymouth (Amalgamation, etc.) Bill was read the third time, and passed.

HOUSE OF COMMONS

WEDNESDAY, APRIL 25TH

Sulphur Fumes from Battersea Power Station

Mr. Alan Todd asked the Minister of Transport whether he was satisfied that the pledge given by the Government on Sept. 26th, 1929, to the representatives of the Chelsea borough council with reference to the emission of sulphur fumes from the Battersea power station had been fulfilled; and if he would make a statement as to the question of emission of smoke and fumes from the power station.—Mr. Oliver Stanley replied: The pledge referred to still holds, and the remaining sections of the new Battersea power station will not be sanctioned unless the gas washing plant already installed is working efficiently. The position at present is that while there is no reason to be dissatisfied with the results so far obtained, the station has not yet been in commercial operation sufficiently long for a final conclusion to be reached.

Medical Treatment of Unemployed Persons

Mr. John asked the Minister of Health whether it was intended that persons in receipt of transitional benefit and who had lost their medical benefit under the National Health Insurance Act should be entitled to medical treatment from the public assistance authorities.—Mr. Shakespeare, Parliamentary Secretary to the Ministry of Health, replied: All persons who are insured under the National Health Insurance Acts are entitled to medical benefit under those Acts. Persons who have ceased to be insured, whether in receipt of transitional payment or not, and who are in need of medical treatment and are not in a position to meet the cost of such treatment, are entitled to have recourse to the public assistance authorities.

THURSDAY, APRIL 26TH

Boys and Corporal Punishment

Mr. Bernays asked the Home Secretary how many boys under 14 were sentenced to corporal punishment in 1933; and whether he was satisfied with the response by magistrates to the official discouragement of the Home Office of the frequent employment of this form of punishment.—Sir John Gilmour replied: Statistics for 1933 are not yet available. A circular letter about the Children and Young Persons Act of 1933 was sent by the Home Office to courts of summary jurisdiction in August last, and in this circular it was pointed out that while in the new Act the power to order a child to be whipped is retained, the practice of the most experienced juvenile courts for many years shows that these courts rarely or never need to exercise this power. The question when use shall be made of any form of penalty authorised by law must be one for the discretion of the justices.

Milk-supplies to Public Institutions

Lieut.-Colonel Heneage asked the Home Secretary whether the contracts of the institutions under his control required the purchase of certified, Grade A, or ordinary standard milk.—Sir John Gilmour replied: As regards schools approved under the Children and Young Persons Act, 1933, some provide themselves with milk from their own farms; the others purchase ordinary standard milk. As regards prisons and borstal institutions, milk contracts require the supply of fresh genuine whole milk, the conditions being substantially the same as those laid down by the Milk Marketing Board. Certified and Grade A milk is not used.

Injuries and Sickness Caused by Police Sports

Mr. Lunn asked the Home Secretary the number of men at present on the sick list as a consequence of injuries received or sickness resulting from participation in police sports.—Sir J. Gilmour replied: At the present time 32 members of the metropolitan police force are on the sick list for the reason stated—one sergeant and 31 constables.

Equalisation of Rents of Council Houses

Mr. Joel asked the Minister of Health the number of councils which, at the present time, were considering schemes for the equalisation of rents under which it was proposed to pool the subsidies and to see that the poorest people get the full benefit and the tenants who could afford it paid economic rents.—Sir Hilton Young replied: Local authorities are not required to report action of this kind, or their consideration of its possibility to me, but under the existing law a general pooling of the subsidies given under two or more separate Acts is not permissible.

Miss Rathbone: Is the right hon. gentleman aware that a considerable number of these local authorities are pooling a part of the subsidy for the relief of poor tenants, and that the Leeds corporation is the only municipality which is pooling the whole of the subsidy and requiring tenants who can afford it to pay the full economic rents as recommended by his own circular?

Sir Hilton Young: I am certainly aware that the development in Leeds goes very much further than anywhere else.

Mr. Mabane: Is it not a fact that in Leeds hundreds of corporation houses are being vacated and are empty?

Sir Hilton Young: I am aware that the experiment being conducted in Leeds is not wholly without friction.

Major Milner: Is the right hon. gentleman aware that in point of fact it is a great success, and that there is a surplus on the rent pool of some thousands of pounds?

No further answer was given.

Scales of Relief for Children

Mr. Hutchison asked the Minister of Health which public assistance authorities had taken steps to raise their scales of relief for children to 3*s*. per head since February of this year.—Sir Hilton Young replied: I am aware that this increase has been made, in the period suggested, by the county borough councils of Bolton, Rochdale, and Salford. I should, however, explain that there is no obligation on public assistance authorities to frame a scale of relief or to report any scale so framed to me, and that there has never been any rule that the relief granted to the head of a family in respect of a child should be fixed at any particular figure.

TUESDAY, MAY 1ST

Medical Branches of Defence Services

Captain ELLISTON asked the Secretary to the Treasury whether he could now announce the decisions of the Government as to the recommendations of the Warren Fisher Report on the medical branches of the defence services.—Mr. HORE-BELISHA replied: The Government have adopted the recommendations of the committee in their application to the medical branches of the Army and Royal Air Force. As regards the Royal Navy it has been considered necessary to modify the scheme recommended in certain particulars. The changes will take effect from to-day, and details will be found in the various orders which are on the point of publication.

MEDICAL NEWS

General Medical Council: Election of Direct Representative

The result of the voting in the recent election of a direct representative for England, in the place of the late Dr. Christine Mary Murrell, was as follows:—

HARRY GUY DAIN, M.B., M.R.C.S.	11,091
EDWARD ANDREW GREGG, L.R.C.P. & S.I.	3,194

Dr. Dain has accordingly been elected a member of the General Council of Medical Education and Registration of the United Kingdom, representing the registered medical practitioners resident in England, for a period of five years from April 27th, 1934.

University of Oxford

On April 26th the degree of doctor of medicine was conferred on F. J. Sale.

University of Cambridge

On April 28th the following degrees were conferred:—

M.D.—F. A. Richards and Hermon Taylor.

M.B. and B.Chir.—Alan Bowen-Davies.

M.B.—R. H. Fish and E. W. Taylor.

B.Chir.—P. R. Goodfellow, H. J. M. Robinson, and W. F. Nicholson.

Royal College of Physicians of London

At a comitia of the college held on April 26th, with Lord Dawson, the president, in the chair, the following members were elected to the fellowship:—

Thomas Gillman Moorhead, M.D. Dub., President of the Royal College of Physicians of Ireland; Duncan Graham, M.D. Toronto (Toronto); Patrick Playfair Laidlaw, F.R.S., B.Ch. Camb. (London); Geoffrey Eden, M.D. Camb. (Birmingham); Helen Marion Macpherson Mackay, M.D. Lond. (London); Walter Rupert Reynell, D.M. Oxon. (London); Richard Christopher Clarke, M.B. Brist. (Bristol); James Riddell Bell, M.D. Melb. (Melbourne); Thos. Sidney Nelson, M.B. Oxon. (London); William Stobie, M.D. Edin. (Oxford); Thomas Arthur Hughes, M.D. Dub. (Lahore); Claude Blaxland Levick, M.B. Sydney (London); Peter Knight McCowan, M.D. Edin. (Cardiff); Maurice Elgie Shaw, D.M. Oxon. (London); Sidney Campbell Dyke, D.M. Oxon. (Wolverhampton); William Moodie, M.D. St. And. (London); William Ernest Lloyd, M.D. Lond. (London); Victor John Frederick Lack, M.D. Lond. (London); Bernard Edward Schlesinger, M.D. Camb. (London); Alan Aird Moncrieff, M.D. Lond. (London); William Edmund Cooke, M.D. Liverp. (Wigan); Edward Revill Cullinan, M.D. Lond. (London); Kenneth Edwin Harris, M.D. Camb. (London); Henry Cohen, M.D. Liverp. (Liverpool); William Robert Fitzgerald Collis, M.D. Camb. (Dublin); William Norwood East, M.D. Lond. (London); Robert Dick Gillespie, M.D. Glasg. (London); Warrington Yorke, M.D. Liverp. (Liverpool); Fergus Robert Ferguson, M.D. Manch. (Manchester); Sir Pendrill Charles Varrier-Jones (Papworth); and John St. Clair Elkington, M.B. Camb. (London).

The following were admitted members of the College:—

Stanley George Browne, M.B. Lond.; William Allen Daley, M.D. Lond.; Ramanlal Ambelal Desai, M.B. Bombay; Kenneth James Franklin, D.M. Oxon.; John Bishop Harman, L.R.C.P.; Arthur Landau, M.B. Cape Town; Charles Roger Tyssen Lane, M.B. Camb.; Gordon Alan Macdona Lintott, M.B. Lond.; Leonard Joseph Alphonse Loewenthal, M.B. Liverp.; Harold Edward MacMahon, M.D.; Naguib Bey Mahfouz; Arthur John Rushton O'Brien, M.B. Edin.; Matthew Burrow Ray, D.S.O., M.D. Edin.; Eric Camillo Ritter, M.B. Glasg.; Cuthbert Harry Rogerson, M.D. Lond.; Martin Richard Thomas, M.B. Lond.; Harold Williamson, M.D. Durh.; Alexander Louis Wingfield, M.B. Lond.; and Barbara Edith Woodhead, M.B. Birm.

Licences were conferred upon 166 candidates (146 men and 20 women) who have passed the final examination of the Conjoint Board, and have complied with the by-laws of the College. The following are the names and medical schools of the successful candidates:—

A. K. Acharya, Calcutta and West Lond.; A. R. Agati, St. Thos.; Helen M. B. Alcock, King's Coll.; E. C. Allibone, Leeds; J. E. O. Amegatcher, Camb. and St. Thos.; J. B. Andosca, Boston and King's Coll.; R. A. Andrews, Camb. and Guy's; M. Appelman, St. Bart.'s; R. C. B. Barbor, Camb. and St. Thos.; A. H. Bartley, Bombay and West Lond.; C. H. D. Bartley, Camb and St. Thos.; H. H. Bayley, Camb. and King's Coll.; R. A. Binning, Camb. and St. George's; L. C. Bousfield, Middx.; J. Boyle, St. Mary's; Joyce M. Brockington and Edith J. R. Browne, Royal Free; J. C. H. Browne, Middx.; A. G. Butters, St. Bart.'s; N. A. Buxton, Camb. and Middx.; E. M. Buzzard, Oxon and St. Thos.; H. Cameron, Guy's; Ruth M. Campbell, Bengal and Royal Free; A. M. R. Cann, Middx.; H. Caplin, London; C. M. Carlyle-Gall, St. Thos.; R. Carpenter, St. Bart.'s; R. M. Clarke, Middx.; C. D. Clements, Univ. Coll.; C. J. Cobbe, St. Thos.; A. N. F. Critchley, St. George's; J. H. J. Crosse and T. M. Daniel, Camb. and St. Bart.'s; H. H. Davies, St. Bart.'s; D. W. A. De Gazon, Univ. Coll.; Audrey P. Dence, Royal Free; Rosalind M. S. Derham, Bristol; A. E. De Sa, Bombay and Middx.; A. M. Desmond, London; J. A. Dhacka, Bombay and Univ. Coll.; Lynette Dowsett, Royal Free; F. W. Dunn, Charing Cross; C. E. Elliott, Camb. and St. George's; H. J. Fenn, King's Coll.; A. B. R. Finn, Camb. and St. Thos.; J. M. Fleming, London; P. A. Flood, Camb. and St. Thos.; J. F. A. Forster, Guy's; J. A. C. Franklin, St. Thos.; Violet Fry, Bristol; L. B. Furber, St. Bart.'s; W. R. Gavin, Camb. and St. Thos.; S. W. Gillman, Univ. Coll.; Bessie W. Goodwill, Birmingham; H. W. Gordon, Witwatersrand and London; R. I. N. Greaves, Camb. and St. Mary's; J. Greenhalgh, Guy's; T. F. Greenwood, Middx.; G. D. Hadley, Camb. and Middx.; G. J. Hamilton, St. Bart.'s; W. H. Hamilton, Guy's; J. W. Hannay, Camb. and London; J. Hardman, Birmingham; J. H. T. Harrington, Oxon. and St. Mary's; L. D. Harris, Cornell and St. Mary's; T. N. Hart, Camb. and Manchester; Violet C. Hart, Royal Free and West London; A. E. M. Hartley, Camb. and St. Mary's; L. A. Hawkins, Camb. and London; Barbara D. F. Hay-Cooper, Royal Free; J. N. Heales, Bristol; D. F. Heath, Birmingham and Durham; R. R. Henderson, St. Thos.; T. S. Heslop, Manchester; R. Hill, St. Mary's; I. W. Hockley, St. Thos.; N. T. Holden, Camb. and Westminster; R. D. Holloway, Camb. and St. George's; M. H. Hosny, Birmingham; A. G. Hounslow, Univ. Coll.; D. A. Hovenden, St. Thos.; H. G. Howitt and G. B. Hughes, London; N. G. Hulbert, Camb. and St. Bart.'s; J. A. C. Hunter, Guy's; D. B. Hyslop, Charing Cross; R. S. Illingworth, Leeds; A. Innes, Camb. and St. Bart.'s; J. E. Jameson, St. Thos.; C. C. Jeffery, London; B. S. Jones, Camb. and London; I. D. Jones, Middx.; A. C. Kanaar, St. Bart.'s; H. R. Kasday, New York and Middx.; L. M. Kelly, St. Thos.; R. L. Kerr, Camb. and St. Mary's; M. A. Khan, Osmania and West London; J. Kingston, London; J. W. J. Knowles, St. Thos.; Hilda I. Lanceley, King's Coll.; K. A. Latter, St. Bart.'s; A. M. Lester, King's Coll.; T. Levitt, Cape and Middx.; Margaret M. C. Louden, Royal Free; D. Lubin, Ohio and Belfast; K. Lumsden, Camb. and St. Bart.'s; W. D. F. Lytle, St. Thos.; W. M. Macleod, St. Thos.; I. Magdi, Cairo and St. Bart.'s; T. F. Malcolm, Manitoba; K. W. Martin, Camb. and St. Bart.'s; L. C. Martin, Camb. and Middx.; J. D. Martin-Jones, Camb. and St. Bart.'s; S. P. Mason, Middx.; H. B. May, Camb. and London; Queenie I. E. May, Royal Free; N. H. Merchant, Bombay and Univ. Coll.; Lida O. Meredith, West London and Royal Free; W. G. Q. Mills, Camb. and St. Thos.; R. H. Moodie, Bristol; J. N. Morris, Univ. Coll.; L. O. Mountford, Camb. and London; D. J. M. Moynahan, St. Bart.'s; J. H. Neal, Middx.; G. P. Neogy, Bengal and London; A. Orlek, Witwatersrand and St. Bart.'s; N. C. Oswald, Camb. and Charing Cross; B. H. Page, Camb. and London; C. G. Parsons, Camb. and Birmingham; J. E. G. Pearson, Oxon. and Middx.; D. S. Piper, Guy's; G. T. Pitts, Camb. and St. Thos.; C. H. G. Price, Bristol; R. E. A. Price, London; Silvia W. Pyddoke, Royal Free; S. Rameshwer, Lucknow and Middx.; T. A. [illegible], Camb. and St. Thos.; K. B. Rogers, St. Mary's; [illegible]; K. G. Seager, St. Mary's; B. Selwyn, Univ. Coll.; J. G. Sheldon, Liverpool; T. L. H. Shore, Camb. and London; H. S. Shucksmith, Leeds; M. Shun-Shin, Univ. Coll.; G. E. T. Soden and H. G. Stanton, St. Bart.'s; W. J. Stokes, London; G. L. R. Tapsall, Madras and St. Mary's; W. P. M. Telfer, St. Bart.'s; Elisabeth J. M. Thomas, Univ. Coll.; A. S. Till, Camb. and Middx.; G. C. Tooth, Camb. and St. Bart.'s; Elsie E. Vincent, Royal Free; J. H. Walters, Camb. and King's Coll.; W. F. Walton, Camb. and St. Thos.; C. R. H. Weekes, Camb. and St. Bart.'s; C. W. Warne, Guy's; Elizabeth B. White, Royal Free; P. A. Wilkinson, Guy's; M. Williams, Camb. and St. George's; J. W. Wishart, Manchester; A. R. Wood, Royal Free and Camb.; O. H. M. Woodbridge, Guy's; and A. R. C. Young, St. Bart.'s.

Diplomas in tropical medicine and hygiene were conferred jointly with the Royal College of Surgeons upon the candidates whose names were given in THE LANCET of April 21st (p. 874).

The diploma in gynæcology and obstetrics was conferred jointly with the Royal College of Surgeons upon K. S. Jayakar, Bombay.

Lord Dawson was re-elected representative of the

College on the governing body of the British Postgraduate Hospital and Medical School.

Dr. C. H. Andrewes is delivering the Oliver-Sharpey lectures on May 1st and 3rd on viruses in relation to the ætiology of tumours, and Prof. O. L. V. S. de Wesselow the Croonian lectures on June 5th, 7th, and 12th on arterial hypertension.

Charles Murchison Scholarships in Clinical Medicine.—An examination for this scholarship will be held at the College from June 19th onwards and is open to students of medicine studying in London or Edinburgh. Further particulars will be found in our advertisement columns.

Scottish Conjoint Board

As a result of recent examinations of the conjoint examining board of the Royal College of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow, the following candidates have been granted the diplomas of L.R.C.P. Edin., L.R.C.S. Edin., L.R.F.P. & S. Glasg. :—

J. B. Coltman, A. B. Daoud, M. W. M. de Silva, P. J. Duff, M. H. Flinter, T. D. Fraser, T. K. Ghosh, Leonard Grech, Sylvia S. Gunn, M. A. Hayford, J. S. Hunter, I. M. Ali Ismail, W. A. Kennedy, T. A. Kester, Arthur Lucas, Adolph Meyer, P. F. Meyer, M. A. Nasr, M. G. Odendaal, M. K. K. Pillai, A. W. Pollock, Michael Siger, J. K. Swanston, I. I. Thomas, J. F. Trigg, E. B. Weeks, and D. S. Williams.

University of London

The senate are inviting applications for the Laura de Saliceto studentship for the advancement of cancer research, which is of the value of £150 a year. Applications should be sent to the academic registrar of the University, South Kensington, S.W.7, before July 1st.

University of London Medical Graduates Society

The annual meeting and dinner of this society will be held at the Langham Hotel, W., on Tuesday, May 8th, at 7 for 7.30 P.M. Applications for tickets should be sent to the hon. secretaries, 11, Chandos-street, Cavendish-square, W.1, not later than to-day, Saturday, May 5th.

Cambridge Graduates' Medical Club

The annual dinner of the Cambridge Graduates' Medical Club will be held at the Langham Hotel, W., on Wednesday, May 9th, at 7.15 for 7.45 P.M., with the president, Dr. H. Morley Fletcher, in the chair. The honorary secretaries are Dr. F. G. Chandler and Mr. W. D. Doherty, and applications for tickets may be addressed to 10, Upper Wimpole-street, London, W.1.

Glasgow University Club, London

This club will dine at the Trocadero Restaurant, Piccadilly-circus, W., on Friday, May 25th, at 7.15 for 7.30 P.M. Sir Robert Muir, F.R.S., will be in the chair. The honorary secretary may be addressed at 62, Harley-house, N.W. 1.

Aberdeen University Club, London

The ninety-first half-yearly dinner of this club will be held at the Trocadero Restaurant, Piccadilly-circus, W., at 7 for 7.30 P.M., on Thursday, May 17th, with Prof. Alexander Low in the chair. The secretary may be addressed at 16, Tregunter-road, S.W.10.

British College of Obstetricians and Gynæcologists

The quarterly meeting of the council was held on April 27th in the College House, with Dr. J. S. Fairbairn, the president, in the chair. Agnes Marshall Cowan (Manchuria) and Charles Leopold Granville Chapman (Grimsby) were elected to the membership of the College.

The president formally admitted to the fellowship :—

Duncan Coutts, India ; Peter Fleming Gow, India ; Gordon Grant, Johannesburg ; Sydney Nuttall Hayes, India ; Maurice Lawrence Treston, India ; and James Hayward Willett, Liverpool.

and to the membership :—

Margaret Emily Anderson, Gavin Stiell Brown, John Lloyd Davies, Charlotte Ann Douglas, Gwyneth Griffith, Kathleen Marguerite Douglas Harding, Jocelyn Adelaide Medway Moore, Percy Peltz, John Marshall Scott, and Arthur Joseph Wrigley.

A silver mace was presented to the College by the Gynæcological Club.

Royal College of Surgeons of England

The council invites applications for election to the office of Hunterian professor, Arris and Gale lecturer, and Erasmus Wilson lecturer for the coming year. Particulars will be found in our advertisement columns.

London Jewish Hospital Medical Society

Dr. Charles Singer, professor of the history of medicine in the University of London, will deliver the annual oration of this society on Thursday, May 10th, at 4 P.M., at the London Jewish Hospital, Stepney Green, E. The subject of the lecture will be the contrast between ancient and modern science.

Will Edmonds Clinical Research Fund

A Fellow is to be elected in June who will receive a salary of £500 under this fund. He must devote the whole of his time to clinical research in a metropolitan hospital, and will be eligible for re-election annually up to a term of five years. Applications should be sent, in proper form, to the honorary secretary of the fund, 68, Great Cumberland-place, London, W.1, not later than June 1st.

Cremation Conference

The Federation of Cremation Authorities and the National Association of Cemetery and Crematorium Superintendents are holding the third annual joint conference at Birmingham from June 25th to 28th. Sir Gilbert Barling is among those who will read papers.

Shenley Mental Hospital

The Middlesex county council announce that the King, who will be accompanied by the Queen, has consented to open this new hospital, near Radlett, Hertfordshire, on Thursday, May 31st.

Norfolk and Norwich Hospital

Last year this hospital treated 6422 in-patients, the largest number on record ; the income of £54,232 also exceeded all previous figures, and left a credit balance of £2947.

East Suffolk and Ipswich Hospital

Last year the contributory scheme of this hospital produced £31,230, which was 59 per cent. of its total income. Every firm in Ipswich is a member.

Liverpool Medical Institution

The fifth Hugh Owen Thomas memorial lecture will be given in the institution on Thursday, May 10th, at 4.30 P.M., by Mr. John Fraser, regius professor of clinical surgery in the University of Edinburgh. Prof. Fraser will speak on lipoid granulomatosis of bone.

A Five-day Week

During the present summer a five-day week will be worked in the Nottingham factories of Boots Pure Drug Company, which employ 5000 people. The premises will be closed from Friday evening until Monday morning, and there will be no reduction of pay. The scheme is at present experimental, but if the results, on review in September, are found to be satisfactory, it may later become permanent—at any rate in the summer months. Lord Trent, the chairman of directors, announces that his firm hope next year to arrange some form of extra holidays, with pay, for their retail employees.

Medical Research Fellowships

The Rockefeller medical fellowships for 1934–35 will shortly be awarded by the Medical Research Council. The value of these fellowships will be not less than £350, exclusive of allowances, and they are given in accordance with the wishes of the Rockefeller Foundation, to graduates who have had some training in research work in the primary sciences of medicine, or in clinical medicine or surgery, and are likely to profit by a period of work at a university or other chosen centre in the United States before taking up positions for higher teaching or research in the British Isles. In special circumstances the fellowships may be tenable at centres of research not in America. Further particulars are obtainable from the secretary of the Council, 38 Old Queen-street, Westminster, London, S.W.1. Applications must be made by June 1st.

Navy Medical Compassionate Fund

At the quarterly meeting of the directors of this fund, held on April 19th, with Surgeon Vice-Admiral Sir Reginald Bond, medical director-general of the navy, in the chair, the sum of £235 was distributed.

University College, London

The fellows of University College held their annual dinner at the college last Monday with Sir John Rose Bradford, M.D., F.R.S., chairman of the college committee, in the chair. Before dinner, those who had been recently elected were admitted to the honorary fellowship or fellowship by the chairman. Emeritus Professor Karl Pearson, F.R.S., is among the new honorary fellows and Mr. Alan Sterling Parkes, D.Sc., F.R.S., among the new fellows.

The Ministry of Health

Mr. E. J. Maude, C.B., has been appointed deputy secretary to the Ministry of Health in succession to Sir Arthur Lowry, C.B., deputy secretary and chief general inspector, who has retired after 42 years of service in the Local Government Board and the Ministry of Health. Mr. T. D. Harrison succeeds Mr. Maude as solicitor and legal adviser to the Ministry, and Mr. H. A. Leggett, C.B., director of establishments, will act as chief general inspector also.

Conference of Voluntary Hospitals

On Wednesday June 13th, the Prince of Wales will open a Conference of Voluntary Hospitals of Great Britain and Ireland, at the Guildhall, London, E.C.2. The speakers at the conference will include Sir Robert Bolam, Mr. E. Rock Carling, Lord Horder, Dr. René Sand and Sir George Newman, and it will end, with the annual meeting of the British Hospitals Association, on Saturday, June 16th. The Duke of York is to preside over the conference dinner at the Guildhall on the 14th. Particulars may be had from the organising secretary at 12, Grosvenor Crescent, London, S.W.1.

National Hospital, Queen-square

The annual report of this hospital for nervous diseases states that no material progress has been made with the extension and rebuilding scheme, but the reconstruction of the surgical department is being strongly urged by the medical committee which points out that if the hospital "is to maintain its reputation" its recommendations "should be put into effect without delay." Last year there were 1459 in-patients whose average stay was 44 days and average weekly cost £3 9*s.* 6*d.* Expenditure exceeded income by £3817, and brought the deficits of six successive years to £27,000.

Worthing Hospital

Sir E. Cooper Perry has succeeded the late Mr. Robert W. Charles as chairman of the governors, and at the annual meeting on March 29th he announced that it had been decided to proceed to a new maternity block which would increase the number of beds from 67 to 78. The deficit on the year's working amounted to £1125. The governors were of the opinion that the Sussex Provident Scheme and the household box scheme were two sources of income most likely to increase. At present each brought to the hospital over £500 a year. The special appeal during 1933 for £4000 for the maternity and pay-patients' wards had raised £3783.

National Health Insurance in South Africa

In the Union House of Assembly at Capetown on March 27th, in reply to a question by Dr. E. P. Baumann whether the Government had taken into consideration the advisability of establishing a State Medical Service in the Union, the Minister of Public Health, Mr. J. H. Hofmeyr, said: "If, as is assumed, the hon. member means by a State medical service a contributory scheme of health insurance such as that in force in Great Britain or Germany, it is not considered practicable at present to establish such a service." The Minister added that he hoped shortly, in connection with the Budget, to give the House full information in regard to provision for the needs of the large section of the population unable, under existing conditions, to secure medical attention.

Donations and Bequests

Dr. Edward John Cave, of Bath, who died on Feb. 16th left estate of the value of £49,679, with net personalty £47,547. He left £6000 to St. Bartholomew's Hospital, for an entrance scholarship to be known as the Helen Cave memorial scholarship.—The late Mr. Joseph Bourne Bradley, of Dudley, Worcs, among other bequests, left £400 to the Dudley District and Bradley District Nursing Home; £400 to the Guest Hospital, Dudley; and £400 to the Royal Orthopædic and Spinal Hospital, Birmingham.—Under the will of the late Mr. Thomas Keaveney, J.P., of Belfast, the Mater Infirmorum Hospital, Belfast, will receive £1000 for a "Keaveney Bed."—The late Sir Alexander Lyle, among other bequests, left £1500 or such larger sum as may be required for the endowment of a bed in the Perth Royal Infirmary, to be called "The Lyle Bed" and £1000 to Greenock Hospital and Infirmary.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, May 8th.

Therapeutics and Pharmacology. 3.30 P.M. Annual General Meeting (at the Pharmaceutical Laboratory, University College). Demonstrations: Sir William Bragg and Mr. R. Paul: 1. Apparatus for Prolonged Artificial Respiration. Katharine H. Coward: 2. Estimation of Antineuritic Vitamin. F. J. Dyer: 3. Estimation of Parathyroid Hormone. J. C. Gage: 4. Standardised Preparation of Digitalin. H. Barcroft: 5. Increase of Systemic Flow Following Occlusion of the Thoracic Aorta. S. L. Cowan: 6. The Rein Thermo-stromuhr. W. Feldberg and O. Krayer: Liberation of Acetylcholine by Dog's Heart during Stimulation of the Vagus. G. W. Theobald: The Influence of Changes in Intra-ureteric Pressure on Water Diuresis. 5 P.M. *Communications:* G. W. Theobald: An Antidiuretic Substance in the Ultra-filtrate of Blood from Eclamptic Patients. H. R. Ing: The Pharmacological Action of Quaternary Ammonium Salts. B. Szabuniewicz: The Alleged Occurrence of Water Diuresis as a Conditioned Phenomenon. G. W. Theobald and E. B. Verney: Water Diuresis and its Inhibition after Complete Denervation of the Kidney.

Psychiatry. 8.30 P.M. Annual General Meeting. Dr. A. Adler. Paper: Aspects of Delinquency.

WEDNESDAY.

Surgery: Subsection of Proctology. 5 P.M. Annual General Meeting. Surgical Treatment of Carcinoma of the Colon; Discussion, to be opened by Dr. Fred W. Ranken (Lexington, Kentucky) and Dr. T. de Martel (Paris), followed by Sir Charles Gordon-Watson and Mr. J. P. Lockhart-Mummery.

FRIDAY.

Clinical. 4 P.M. Cases of Affections of the Gall-bladder: Mr. Mortimer Woolf, Dr. Dorothy Hare, Mr. Cecil Joll, Dr. Charles Newman, and Dr. J. E. A. Lynham. 4.45 P.M. Annual General Meeting. Short Papers on Gall-bladder: Prof. H. H. Woollard, Dr. C. E. Newman, Dr. H. K. Graham Hodgson, and Mr. A. J. Walton.

Obstetrics and Gynæcology. 8.15 P.M. Annual General Meeting. Discussion on Genital Prolapse, to be opened by Mr. Victor Bonney, Prof. Fletcher Shaw, Prof. A. Leyland Robinson, and Dr. C. A. Robinson.

Physical Medicine (at Harrogate). Annual General Meeting.

SATURDAY.

Physical Medicine (at Harrogate).

MEDICAL SOCIETY OF INDIVIDUAL PSYCHOLOGY.

THURSDAY, May 10th.—8.30 P.M. (at 11, Chandos-street, W.), Dr. Mary Ferguson and Dr. Hilda Weber: Case Reports Illustrating Menopausal and Post-menopausal Neuroses.

SOUTH-WEST LONDON MEDICAL SOCIETY, Bolingbroke Hospital, Bolingbroke-grove, Wandsworth Common.

WEDNESDAY, May 9th.—9 P.M., Mr. C. P. G. Wakeley: Head Injuries.

PADDINGTON MEDICAL SOCIETY.

TUESDAY, May 8th.—9 P.M. (at the Gt. Western Royal Hotel, Paddington), Addresses by Representatives on the Work of the London Panel Committee. The meeting will be open for discussion on any matter connected with the N.H.I.

accelerated and 8 months after the commencement of treatment the eczema had completely cleared up.

That was three months ago and James' skin is still clear and there have been no further attacks of asthma.

ETHEL was the elder of two girls with a young, hearty mother and an affectionate father. She wept most of the day, started when spoken to and was terrified of the dark. No medical reason for her pale face and thin body and the dark rings under her eyes could be discovered. At school she was said to be exceedingly slow and unable to concentrate. During her work at the Institute, layer upon layer of fear and struggle were shown to be in her mind. The bluff, hearty mother, having no other outlet for her practical emotions, had found it impossible to allow Ethel to grow out of that state of babyhood in which everything had to be done for her. The violent revolt of the child's nature resulted in the fears and nervousness.

When Ethel first came to the Institute she sat about listlessly and was unable to carry out any task calling for concentration. Later, she quickly improved. Interviews with the mother modified her attitude to the child. Through the work carried out in the playroom the inhibitions in Ethel's mind slowly cleared away, her physique and appearance improved, and, from being a backward child, she became, by the time she was discharged, equal in ability to any normal child of her age.

Further information may be obtained from the Secretary of the Institute at 26, Warwick-avenue, London, W.9.

BUDGET RELIEF ON SMALL INCOMES

CHARTERED ACCOUNTANT, who as a member of a recognised professional body does not subscribe his name, writes: "With reference to the paragraph in your journal of last week drawing attention to the limited relief given by the Budget to those with small incomes, much of the point made by the income-tax consultant was lost in the choice of examples which he gave. The emergency budget of 1931–32 increased the standard rate from 4*s*. 6*d*. to 5*s*., at the same time cutting severely the allowances; in 1934–35 the standard rate is again reduced but none of the allowance cuts are restored, entailing a definite hardship. Taking a married man with one child whose income is all earned, the following table shows that the load on moderate incomes is still a severe one and, further, that the lower the income the greater the hardship still endured.

Income.	Income tax.			Increase 1934–35 over 1930–31
	1930–31	1933–34	1934–35	
£1250	£139 1 6	£178 2 6	£160 6 3	£21 4 9
650	26 10 0	58 2 6	52 6 3	25 16 3
400	4 16 0	15 0 0	13 10 0	8 14 0

The taxation burden of the £1250 a year man is 15 per cent. greater than in 1930–31, whereas his poorer countrymen at £650 and £400 bear an increased load for the current year of no less than 97 per cent. and 181 per cent. respectively compared with pre-emergency conditions. The restoration of the allowances to 1930–31 figures would have given greater benefit to the professional classes as a whole than the 6*d*. cut in the standard rate of tax."

FUN IN BED[1]

WE have here brought together a number of essays, rhymes, jokes, and problems with the view of cheering the later stages of the sojourn in the hospital or nursing-home by suitable reading. The menu is so varied that every palate must find in it some item that is agreeable, and as a whole a ludicrous feast is provided. Some of the old facetiæ were worth reproducing, some were not, but even in such a comment it should be remembered that there is no standard by which what is generally amusing can be assessed. "The secret of a quick cure," says the editor to the patient, "is to relieve your boredom but not to increase your fatigue," and he and his distinguished collaborators, alive and dead, have done much in the indicated directions. The fun for the intelligent reader lies in the malicious fact that both he and his illnesses, and his doctors, nurses, and their ministrations, are all being mocked at. As a rule the gibes are either in themselves good-natured, or are related to such preposterous circumstances that no serious wound is inflicted. But this is not always so, and the portrait of Miss Lyons as drawn by Mr. Ring Lardner, is a loving piece of cruelty.

IN reference to Prof. E. H. Kettle's article on the Detection of Dangerous Dusts, published in our last issue, it should have been stated that this work was done under a grant for expenses from the Medical Research Council.

THE MAKING OF MODERN SPECTACLES.—Theodore Hamblin, Ltd., have issued an invitation to ophthalmic surgeons to their works at 28–32, Aybrook-street, London, W. 1 (near High-street, Marylebone), for a demonstration in the making of modern spectacles and ophthalmological instruments. The production of lantern slides for teaching purposes will also be shown. Up to the end of June the demonstration takes place on any week-day at 10.30 A.M. or 2.30 P.M.; Saturdays at 10.30 A.M. only. A tour of the works takes a little under two hours.

Appointments

HARVEY, R. S., M.B., B.S. Lond., has been appointed Hon. Medical Officer in Charge, Injection Clinic, Royal Waterloo Hospital for Children and Women.

MILLER, ARTHUR, F.R.C.S. Edin., D.L.O., Assistant Aurist, London County Council.

NIXON, WILLIAM C. W., M.D. Lond., F.R.C.S. Eng., M.C.O.G., Assistant Obstetric Surgeon, with Charge of Out-patients, to St. Mary's Hospital.

Sheffield Royal Infirmary: WAYNE, E. J., M.B., Ch.B. Leeds, M.R.C.P., Hon. Associate Physician; and RAYNER, G. H., L.D.S. Sheff., Hon. Asst. Dental Surgeon.

Certifying Surgeons under the Factory and Workshop Acts: GRANT, R., M.B., Ch.B. Edin. (Falkirk); MILLER, A., M.B., Ch.B. Glasg. (Larkhall, Lanarkshire); and SAVAGE, E., L.R.C.P. Lond., M.R.C.S. (Caerphilly).

Births, Marriages, and Deaths

BIRTHS

ASERMAN.—On April 24th, at St. John's Wood-terrace, N.W., the wife of Dr. David Aserman, of a daughter.

FORD.—On April 26th, at a nursing-home, the wife of Dr. R. Kelson Ford, St. Olave's Hospital, Rotherhithe, S.E., of a son.

KNOX.—On April 23rd, at High-street, Tring, Herts, the wife of Dr. Norman Knox, of a daughter.

SWINDELL.—On April 28th, at Westwood-road, Southampton, the wife of Dr. R. S. Swindell, of a son.

MARRIAGES

NIXON—YSEBRAND.—On Feb. 19th, William Nixon, M.D., F.R.C.S., to Miss Vroukje (Vennie) Ysebrand, daughter of the late Mr. and Mrs. Hendrick Ysebrand, of The Hague, Holland, and Durban, South Africa.

DEATHS

RIDDELL.—On April 26th, at Holly House, Plumstead Common-road, Woolwich, Dr. D. F. Riddell, M.C., M.A., M.B., Ch.B., D.P.H.

RUTHERFORD.—On April 25th, suddenly, from heart failure, at Budleigh Salterton, Vickerman H. Rutherford, M.A., M.B., of [illegible] 's Park, N.W., aged 73.

SPREAT.—On [illegible] Oakleigh Park, Frank Arthur S[illegible]

STURGE.—On [illegible] an accident, William Howard Sturge, M.D., of Hoddesdon, Herts.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

ADDRESSES AND ORIGINAL ARTICLES

THE HORMONES AND THEIR CHEMICAL RELATIONS *

BY E. C. DODDS, M.V.O., M.D., D.Sc., F.R.C.P. Lond.

COURTAULD PROFESSOR OF BIOCHEMISTRY IN THE UNIVERSITY OF LONDON; DIRECTOR OF THE COURTAULD INSTITUTE OF BIOCHEMISTRY AT THE MIDDLESEX HOSPITAL

LECTURE II

Synthetic Compounds resembling Œstrin

THE constitution of the œstrus-producing hormone and the pharmacologically active derivatives have already been discussed. As pointed out, the actual synthesis of the œstrin molecule is fraught with the very greatest difficulty, and it was decided to investigate the activity of synthetic organic compounds whose structure resembled in one direction or another that of œstrin (Cook and Dodds, 1933; Cook, Dodds, and Hewett, 1933; Cook, Dodds, Hewett, and Lawson, 1934; Cook, Dodds, and Greenwood, 1934).

Since œstrin contains a partly hydrogenated phenanthrene system containing oxygen groups, it seemed natural first to investigate simpler compounds of this type. Phenanthrene itself was found to be completely inactive, but the compound 1-keto-1 : 2 : 3 : 4-tetrahydro-phenanthrene was found to possess definite œstrogenic activity; this compound is represented by the formula shown in Fig. 7. When this is injected in doses of 100 mg. into castrated rats, it was found that within some 40 hours full œstrus had developed, including uterine changes. The œstrus is of very prolonged duration, lasting in some cases for 20 days. It would appear therefore that it is possible to reproduce all the known phenomena of œstrus in the rat and mouse with this compound. Moreover, when it is injected into immature female mice, premature puberty is induced. In the immature female rat and mouse the vagina is represented by a solid cord of cells which become canalised either at puberty or following the injection of œstrin. This keto-tetrahydro-phenanthrene compound is capable of causing canalisation of the vagina, and of inducing œstrus in these animals.

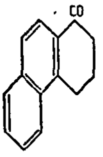

FIG. 7
1-Keto-1 : 2 : 3 : 4-tetrahydrophenanthrene.

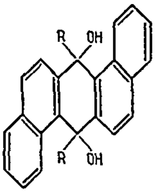

FIG. 8
Dibenzanthracene diols.

Another series of compounds have been very carefully studied and these include derivatives of 1 : 2 : 5 : 6-dibenzanthracene in which the ring-system is partly reduced and hydroxyl groups introduced.

It will be observed that the molecules of these substances are symmetrical, and that each half of the molecule is of the same type as 1-keto-1 : 2 : 3 : 4-tetrahydro-phenanthrene. A series of diols having the general constitution 9 : 10-dihydroxy-9 : 10-dialkyl-9 : 10-dihydro-1 : 2 : 5 : 6-dibenzanthracene have been investigated; the graphic formula is seen in Fig. 8.

Now if the di-methyl compound be made, this, when injected, is without activity in doses of 100 mg. The di-ethyl compound, however, shows evidence of activity in doses as small as 1 mg. It is thus over 100 times as potent as the keto-tetrahydro-phenanthrene compound.

Ascending the alkyl series, we next encounter the di-*n*-propyl, and the activity of this compound is so great that 0·025 mg. will produce all the signs of œstrus in castrated rats. It is thus 40 times as active as the di-ethyl, and 4000 times as active as the phenanthrene compound. This substance is considerably more active than the tri-hydroxy-œstrin, which is one of the natural œstrus-producing agents.

Ascending the series still further we find the next homologue in di-*n*-butyl: this shows less activity than the di-*n*-propyl in that 0·1 mg. represents the effective unit. That is to say, it has about quarter the activity of the di-*n*-propyl compound.

Increasing the length of the side-chain shows that the di-*n*-amyl homologue is inactive, whilst the six-carbon atom side-chain in the next homologue, the di-*n*-hexyl, is also inactive. Table I. shows the relative activity of members of this series.

TABLE I.—*The Activity of Members of the Series* 9 : 10-dihydroxy-9 : 10-dialkyl-9 : 10-dihydro-1 : 2 : 5 : 6-dibenzanthracene.

Substance.	No. of animals.	Dose in mg.	Per cent. positive.	Remarks.
Di-methyl ..	Rats, 5	100	nil	—
Di-ethyl ..	,, 5	100	100	Œstrus lasted 13 days.
	,, 5	10	100	,, ,, 13 ,,
	,, 5	1·0	100	,, ,, 6 ,,
Di-*n*-propyl	,, 5	5	100	—
	,, 5	1·0	100	—
	,, 5	0·1	60	—
	,, 10	0·05	80	—
	,, 10	0·025	40	—
Di-*n*-butyl	,, 10	100	100	Œstrus lasted 28 days, animals then killed.
	,, 9	1·0	50	Œstrus lasted 48 hours.
	,, 14	0·1	50	,, ,, 36 ,,
	Mice 11	1·0	100	Animals in œstrus when killed on 10th day.
	Rats, 10	10	90	Suspension in water per os.
	,, 10	1·0	10	
Di-*n*-amyl ..	,, 5	100	nil	—
Di-*n*-hexyl ..	,, 3	100	nil	—
1-keto-1 : 2 : 3 : 4-tetrahydro-phenanthrene	Rats, 36	100	100	Œstrus lasted 20 days.
	,, 5	100	nil	Suspension in water administered per os.

This is a very instructive series, since it shows how the chemist can manufacture what might be termed a skeleton key with which to open the œstrus lock. The real key is ketohydroxy-œstrin, which is produced by the body. The skeleton key is the dibenzanthracene compound which we have indicated. By building up artificial teeth, so to speak, on the key, it is possible to open the lock with difficulty with the di-ethyl; but by putting on another tooth in the di-propyl, the lock slides back with ease, in fact, with just as much ease as with one of the real keys provided by nature. Another tooth in the di-butyl compound makes the key a little stiff, whilst yet another in the di-amyl makes it jam. It is also possible to show that these compounds, when administered, give an increase in the size of the uterus similar to that which occurs in natural œstrus.

In order to prove that the lock has been genuinely opened and not forced, it can be shown by a further series of experiments the effect of two of these compounds on the plumage of the capon (Cook, Dodds, and Greenwood, 1934). It is a well-known fact that the brown leghorn capon retains its male plumage, and if large doses of œstrin are injected subcutaneously into such a bird, the plumage changes from male to female. We were able to show that with two of these compounds—namely, 1-keto-1 : 2 : 3 : 4-tetrahydro-phenanthrene and 9 : 10-dihydroxy-9 : 10-di-*n*-butyl-9 : 10-dihydro-1 : 2 : 5 : 6-dibenzanthracene—even this lock was capable of responding to our synthetic key. Fig. 9 shows the effect on the plumage of injecting these compounds. The birds were brown leghorn capons whose plumage showed male characteristics. On injecting the compounds mentioned it can be seen that in the growing feathers there is a rapid change from the male to the female type. This is particularly well shown in feathers from the breast region. The markings in the illustration indicate the male and female areas in the feathers, but the striking character of these changes cannot of course be fully appreciated without coloured reproduction.

We can state, therefore, that, in so far as is known up to the present, these compounds possess all the known activity of the natural œstrus-producing hormone.

Specificity of Hormones

The significance of these observations is considerable, since they throw grave doubt on the question of specificity of hormones. The original conception postulated that hormone action was one of the most specific. Whilst it is known that para-hydroxy-phenols and their derivatives are capable of causing a slight rise of blood pressure, it would have been deemed incredible that so complicated a series of events as occur in the œstrus cycle could be initiated and maintained by any other than the naturally occurring hormone. Here, however, we see compounds of somewhat differing structures which are capable of reproducing the whole phenomenon, not only in mammals, but also in birds. *It appears justifiable to assume that there are certain parts of the œstrin molecule which are necessary to reproduce the physiological activity, and that these compounds of ours also possess this.*

The significance of this to the organic chemist is great, since *it may mean that it is not necessary* to synthesise the whole of the elaborate molecules that occur in nature, but that skeleton keys may possibly be found for many of the other hormones. At the present time it is impossible to state the exact groupings necessary in the substances for this activity. In all the active compounds the phenanthrene nucleus is to be seen. We now know, however, that even this is not essential, since we have found evidence of œstrogenic activity with the derivative of anthracene—namely, 1-keto-1 : 2 : 3 : 4 : 5 : 6 : 7 : 8-octa-hydro-anthracene—which is represented in Fig. 10. Research has been extended on these lines, and *it is possible to state from unpublished data (Cook, Dodds, and Lawson) that definitely active anthracene derivatives may be obtained.* The important factors seem to be a certain degree of unsaturation in a condensed carbon ring-system together with polar groups. These are probably necessary for a high order of activity, although definite activity of a low order was shown by some compounds which contain no oxygen. A great many compounds were tested with negative results.

These results provide a possible explanation for the very remarkable experiments carried out by Aschheim and Hohlweg (1933), who show that the extraction of a wide variety of bituminous substances is capable of yielding products with very definite œstrogenic activity.

Certain coals, mineral oils, &c. were used as starting material in the preparation of the œstrogenic substance. Aschheim and Hohlweg advanced the very attractive theory that this œstrogenic substance in coal was in effect that variety of the œstrus hormone that is known to be present in plants, and which was later called *tokokinin*. It has been shown that tokokinin has the same constitution as keto-hydroxy-œstrin, and according to Aschheim and Hohlweg's ingenious theory, the œstrogenic activity of extracts from coal could be attributed to the tokokinin of primeval forests which had been preserved in the form of coal. In view, however, of our results it would appear that such an assumption is not necessary, since it is well known that extracts of coal will contain compounds of the same type of structure as those which have been proved to be capable of giving rise to œstrus. We ourselves have shown that certain of the ulmins of coal possess definite œstrogenic activity.

In order to complete a review of compounds capable of causing œstrus apart from the naturally occurring hormone, it is necessary to refer to the statement made by Coke (1930) that clupanodonic acid possesses marked œstrus-producing activity. Now this compound is a straight chain, unsaturated fatty acid obtained from certain fish oils. A very careful investigation has been made into this problem, but it has been found impossible to confirm the œstrus-producing activity of this compound. We were able, however, to demonstrate low-grade activity in certain highly unsaturated fatty acids of the general formula of clupanodonic acid.

This raises the very interesting possibility that perhaps the body possesses the power of converting the straight chain into a carbon ring compound. From the chemical point of view it has been proved that cyclisation of such a highly unsaturated compound does occur (Edisbury, Morton, and Lovern, 1933). As, however, the activity is so small, the other possibility—namely, that the fish oils contained a trace of œstrin which was not eliminated in the purification process—must be borne in mind. Up to the present, therefore, it is safe to say that all the synthetic œstrus-producing substances appear to belong to the condensed carbon ring system, and that the most powerful possess the phenanthrene nucleus.

Carcinogenesis and Œstrogenesis

The hydrogenated phenanthrene ring type of compound, as already pointed out, has only recently been recognised as a normal constituent of the body. A list of the typical compounds of the body belonging to this group has been given earlier together with the structural formulæ. Mainly through the work of E. L. Kennaway and his co-workers at the Cancer Hospital, it has been proved that a carcinogenic agent present in tar also belongs to this particular type of chemical compound (Kennaway, 1924, 1925, 1930; Cook, Hieger, Kennaway, and Mayneord, 1932; Cook, 1932). It will here be necessary to consider the question of carcinogenesis in some detail.

The observations of industrial cancer led to the suspicion that tar was capable of producing malignant disease when applied to the skin. This was first proved by Yamagiwa and Ichikawa (1915, 1917, 1918) who, in 1915, were able to demonstrate experimentally that on application of tar to the skin of rabbits an epitheliomatous condition in a large proportion of cases resulted. Tsutsui (1918) repeated these experiments with mice in 1918, and this was confirmed by Passey in 1921 who used soot (Passey, 1922). It was found necessary to continue the experimental painting for very long periods, and nine months to a year was frequently necessary in order to produce a malignant tumour.

It was at first assumed that the tar acted by producing a chronic irritation which later became the subject of malignant change. Doubt, however, was cast on this view by the observation that not all tars were capable of causing malignant changes. In a very important investigation Kennaway (1924, 1925) showed that the carcinogenic agent could be produced by heating acetylene or isoprene in the presence of hydrogen. This proved conclusively that it was possible to obtain a carcinogenic agent which contained only carbon and hydrogen. Mayneord in 1927 studied the fluorescent spectrum of these synthetic mixtures, and observed the similarity of the spectrum to that of the carcinogenic tar. This work, which was continued by Hieger, suggested that the mixtures contained hydrocarbons of the polycyclic aromatic type. An investigation was at once commenced on the synthesis of a series of these compounds and a study of them from the point of view of their ability to produce carcinoma when painted on to the skin of mice. In a number of papers these workers (Cook, 1932; Cook, Hewett and Hieger, 1932; Cook, Hieger, Kennaway, and Mayneord, 1932) showed that a series of compounds related to 1 : 2-benzanthracene possessed carcinogenic properties. The only compounds of this series that we need consider at the present time are 1 : 2 : 5 : 6-dibenzanthracene, 1 : 2-benzpyrene, and 5 : 6-*cyclo*penteno-1 : 2-benzanthracene (Fig. 11). It can be seen at a glance that these carcinogenic compounds bear some resemblance to the group of substances that we discussed earlier.

The gradual elucidation of the structure of cholesterol, vitamin D, and the sex hormones has increased the theoretical importance of the work of Kennaway and his colleagues, since prior to these investigations it might have been argued that the production of tar cancer was of purely academic interest, as the carcinogenic agents apparently bore no relationship to substances taking part in the composition of the body. Their extensive investigations, however, have shown that the carcinogenic hydrocarbons belong to this form of condensed carbon ring compounds, and, as has been pointed out by Cook, the processes which would be entailed by the formation of these compounds from the naturally occurring sterols and bile acids would involve reduction, dehydration, and dehydrogenation, and might readily occur in the animal body; it seems possible that these carcinogenics might result from these processes operating upon degradation products of sterol metabolism (Cook, 1933).

The most potent synthetic œstrus-producing agent obtained by us is 9 : 10-dihydroxy-9 : 10-di-*n*-propyl-9 : 10-dihydro-1 : 2 : 5 : 6-dibenzanthracene which, it can be seen, is a derivative of 1 : 2 : 5 : 6-dibenzanthracene, the carcinogenic hydrocarbon (Fig. 12).

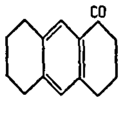

FIG. 10
1-Keto-1 : 2 : 3 : 4 : 5 : 6 : 7 : 8-octa-hydro-anthracene.

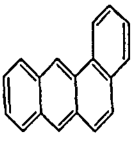

FIG. 11.—1 : 2-Benzanthracene.

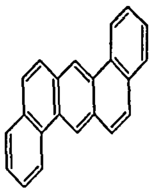
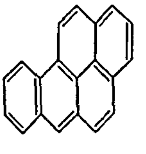
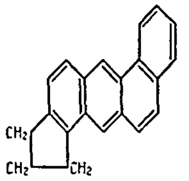


1 : 2 : 5 : 6-Dibenzanthracene



1 : 2-Benzpyrene.



5 : 6-*cyclo*-Penteno-1 : 2-benzanthracene.

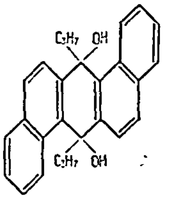


FIG. 12
9 : 10-Dihydroxy-9 : 10-di-*n*-propyl-9 : 10-dihydro-1 : 2 : 5 : 6-dibenzanthracene.

In view of the resemblance of the molecular structure of these two compounds, it was decided to investigate the carcinogenic hydrocarbons to see whether they possessed any œstrogenic activity. Accordingly a series of tests were made in which 1 : 2 : 5 : 6-dibenzanthracene, 1 : 2-benzpyrene, and 5 : 6-*cyclo*penteno-1 : 2-benzanthracene were used. With 1 : 2 : 5 : 6-dibenzanthracene completely negative results were obtained; but with the 1 : 2-benzpyrene and the 5 : 6-*cyclo*penteno-1 : 2-benzanthracene it was found possible to produce a full œstrus response by the injection of 100 mg. of the compound. The usual strict criteria for true œstrus was applied rigorously in these two instances, and the net results of these investigations establish the fact that these two compounds possess dual activity—namely, the power of carcinogenesis and œstrogenesis (Cook and Dodds, 1933). It must, however, be pointed out that the œstrogenic action, though definite, is only feeble, and that the main pharmacological action of these compounds lies in their carcinogenic powers. For example, the dibenzanthracene molecule is carcinogenic in the aromatic state, but œstrogenic when suitably hydrogenated and supplied with hydroxyl groups.

I believe that this is the first instance of the description of two entirely separate actions of a single molecule, and this again throws considerable doubt on the whole conception of hormone activity; not only have we already proved the lack of specificity of hormones, but have proved now that a single substance of known constitution may have at least two entirely separate actions initiating such differing processes as œstrus and the production of carcinoma. There is not at the moment sufficient evidence to warrant a great deal of speculation, but two possible thoughts arise to the mind: either the phenomena of œstrus and carcinoma are closely related or, alternatively, the carcinogenic hydrocarbons bear the same relationship to the production of cancer that the synthetic œstrus-producing agents bear to the œstrus phenomenon—namely, that they are both skeleton keys. It must be admitted that the excessive cellular proliferation occurring in the early stages of œstrus bears a superficial resemblance to certain phases of carcinoma.

Œstrogenic Activity of Vitamin D

As has already been mentioned, the condensed carbon ring group of compounds also includes vitamin D or calciferol. The vast amount of chemical work that has been pursued on this subject has shown that it is possible to take the inert sterol, ergosterol, and by irradiation with ultra-violet light under suitable conditions, to confer upon it the activity associated with vitamin D. By the application of chemical methods it has been possible to isolate in crystalline form the vitamin from the products of irradiation, but the exact constitution of this substance is not yet determined. The formula of ergosterol is shown in Fig. 13. From what is known of its constitution at the present time it can be seen that it is at any rate closely related to the group of compounds that we have discussed.

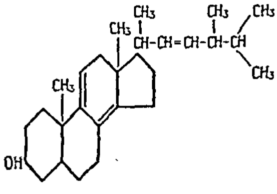

FIG. 13.—Ergosterol.

Bearing in mind the very remarkable observations on the dual activity of benzpyrene and 5 : 6-*cyclo*penteno-1 : 2-benzanthracene, it was felt that a careful trial of sterols related to ergosterol and calciferol for œstrus-producing activity would be interesting. Again, the same elaborate precautions were taken to be sure that any effects produced represented the whole of the œstrus phenomenon. The ovariectomised animals were injected with a solution of the sterol in oil, and 100 mg. were administered in each case. It was found that the greatest activity was possessed by neo-ergosterol; 40 per cent. of the animals injected with this compound developed full œstrus. In the case of calciferol full œstrus was developed in 20 per cent. of the animals, while with ergosterol 20 per cent. of the animals also showed definite evidence of œstrus-producing activity.

In all cases a number of animals were killed at the height of œstrus, and the characteristic enlargement and distention of the uterus was found. In the case of those injected with calciferol, the animals died at a later date with the characteristic symptoms of hypervitaminosis, but it must be emphasised that the œstrus changes occurred before there was any sign of intoxication. It must of course be borne in mind that the amount of calciferol required to produce œstrus is quite out of proportion to that required to protect an animal against rickets.

An interesting point was brought out by running a series of control animals which were injected with parathormone. These animals developed a hypercalcæmia similar to that obtained in hypervitaminosis, but no œstrus resulted. One can therefore definitely state that elevation of blood calcium does not produce œstrus, and that the œstrogenic activity of vitamin D appears to be quite apart from its power to raise the blood calcium content.

We have therefore a very striking confirmation of the observation that a single molecule may possess at least two entirely separate physiological effects, in this case antirachitic and œstrogenic activity. Until this observation was made this dual activity had only been observed with the synthetic carcinogenic hydrocarbons. In the case of vitamin D, however, we were able to reproduce the same phenomena with a naturally occurring substance. Again, it is too early to speculate upon the theoretical process underlying these surprising observations. It seems impossible to imagine that all these groups of compounds are converted in the body of the ovariectomised animal into œstrin, and there is certainly no evidence for such an assumption at the present time. In any case, these observations taken all together indicate the extreme importance of the

TABLE II.—*Relative Potencies of Sterols*

Substance.	No. of rats	Dose in mg.	Per cent. positive.	Remarks.	Method of Preparation.
5 : 6-*cyclo*penteno-1 : 2-benzanthracene ..	10	100	30	—	Cook (1931).
1 : 2-benzpyrene ..	10	100	30	—	Cook, Hewett, Hieger (1933).
Neo-ergosterol ..	10	100	40	—	Inhoffen(1932).
Calciferol	10	100	20	3 died.	—

1 : 9-dimethyl-phenanthrene ..	5	100	60	—	Haworth and Mavin (1932).
Clupanodonic acid (after treatment with bromine)	5	50	50	1 died.	—
Coal ulmins	5	100	40	—	—

sterol group in the metabolism, not only of animals, but also of human beings. Whether the phenomena associated with rickets, malignant disease, and sex activity are all related, or whether all the locks are capable of being opened by skeleton keys, remains yet to be proved. It can be seen that in this particular sterol group there is no œstrogenic activity with cholesterol, but the potency increases with the increasing degree of unsaturation rising to a maximum in the case of neo-ergosterol. Table II. indicates the relative potencies of vitamin D, &c.

The Thyrotropic Hormone

It will be remembered that in Lecture I. the various hormones secreted by the anterior lobe of the pituitary were discussed, and amongst them appeared the thyrotropic hormone. It would seem that this hormone bears a very similar relationship to the thyroid to that which prolan bears to the ovary. We have already seen that prolan acts upon the ovary and stimulates it to produce œstrin and allied compounds. The thyrotropic hormone stimulates the thyroid to produce its own hormone, thyroxine. It will perhaps be advisable to review very briefly the experimental evidence of the existence of the thyrotropic hormone.

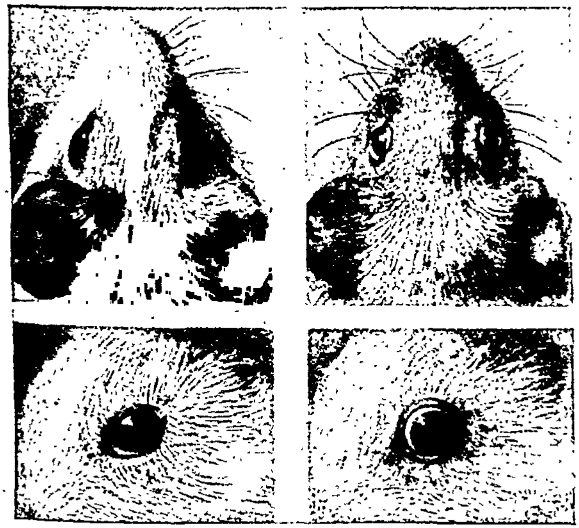

FIG. 14.—Exophthalmos in the guinea-pig. Reproduced from the *Bulletin* of the Johns Hopkins Hospital.

As in the case of prolan in relation to the ovary, the evidence produced by a study of cases of Simmonds's disease indicates the connexion between the anterior lobe of the pituitary and the thyroid gland. It has also been shown that removal of the pituitary gland causes either reduction of development or atrophy of the thyroid (Adler, 1914; Allen, 1916: Smith, 1916; Foster and Smith, 1926; Smith, 1927; Richter and Wislocki, 1930). Several of these observers noted the decrease in basal metabolic rate, and Foster and Smith (1926) and also Richter and Wislocki (1930) noted that the changes can be prevented by injection of an extract of the anterior lobe. Moreover, the addition of an extract of the anterior lobe of the pituitary to the fluid in which axolotls are kept initiates a metamorphosis. The metamorphosis is preceded by hyperplasia of the thyroid gland.

In 1929 Max Aron published an account of the action of an extract of the anterior lobe of the hypophysis upon the thyroid of the guinea-pig. In a later series of papers in 1930 he reported a very careful study of this hormone and showed that there was great hypertrophy of the parenchyma of the gland associated with liquefaction and final disappearance of the colloid; if the injections be discontinued the thyroid gland returns to its normal state (Aron, 1929 and 1930,[1, 2]).

Krogh, Lindberg, and Okkels (1932) made a very careful histological investigation of the thyroids of guinea-pigs following prolonged treatment with anterior lobe extract; they maintained that whilst the glands gave the appearance of having returned to normal after cessation of injections, it was found that the Golgi apparatus still showed the hyperplasia in increase which is characteristic of Graves's disease.

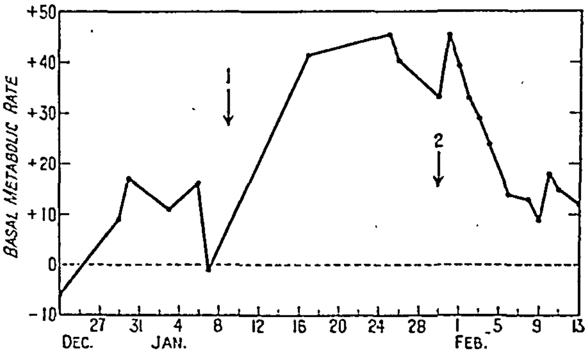

FIG. 15.—Chart showing effect of thyrotropic hormone on the basal metabolic rate of a woman (age 27). Administration of the hormone, in doses of 600 mouse units daily, was begun at the point marked 1 (Jan. 9th) and was stopped at 2 (Jan. 30th).

Some of the first observers to study the effects of the hormone upon the basal metabolic rate of animals were Verzár and Wahl (1931). They showed that it is possible to increase the basal metabolic rate to a very considerable level and that this falls on withdrawing the extract. They further made the interesting observation that this rise in basal metabolic rate could be controlled by the administration of potassium iodide. It was also found impossible to produce hyperactivity of the thyroid in an animal receiving large doses of potassium iodide. This observation was also made independently in my laboratory.

It is very interesting to compare this phenomenon with the well-known effect of iodine in reducing the high basal metabolic rate in persons with thyrotoxicosis. In general it may be stated that the increase in basal metabolic rate is directly dependent upon the amount injected.

A still further effect of this hormone is the production of exophthalmos in animals. This has been successfully demonstrated by Hogben (1922–23) and by Spaul (1923–24); it has also been observed in ducks and guinea-pigs by Schockaert (1931[1, 2] and 1932) and by Loeb and Friedman (1931–32.) The following illustration is reproduced from a paper by Friedgood (1934) and shows very clearly the marked exophthalmos occurring in a guinea-pig (Fig. 14.)

It would appear that here we have an experimental method of producing Graves's disease, and as in the case of Graves's disease the condition can be controlled by the administration of iodine.

With regard to the chemical properties of the extract, very little at present is known. It is apparently of a protein character and is readily destroyed by heat and in alkaline solution. It seems, therefore, to belong to the protein group and to correspond in properties roughly with hormones such as prolan and insulin. The accompaning chart shows a typical experiment made in my laboratory upon a volunteer with this material (Fig. 15).

Guinea-pigs were used for the animal experiments and their oxygen consumption was measured by a modified Krogh apparatus.

I have made a very careful study of the urine of patients suffering from Graves's disease and thyrotoxicosis in the hope of finding a hormone in the urine in the same manner that one finds prolan in the case of pregnancy, but so far no conclusive evidence has been obtained. By a modification of the method of Dickens (1930) for the separation of prolan, it was possible to obtain definite though small yields of a thyrotropic substance. It has, of course, been conclusively shown by many observers that this hormone is without effect upon the basal metabolic rate of animals from whom the thyroid has been removed. We can see, therefore, that the relationship of the pituitary gland to the thyroid resembles in many respects the relationship that it holds to the ovary.

ROYAL FREE HOSPITAL.—At the annual meeting recently, Lord Riddell, the president, stated that during the past year an average of 1000 patients had been treated daily, including 100 children in the Eastman Dental Clinic. The nurses' home had been completed at a cost of about £150,000; two new wards were opened for ear, nose, and throat cases, with 30 beds and a theatre; the pay beds have been increased to 23. The Albert Levy wing at the Queen Mary building, comprising an obstetric and gynæcological out-patients' department and an electrotherapeutic and massage department, has been brought into full operation. Patients' dietaries have been revised to bring them into accord with modern ideas. Sir Hilton Young, Minister of Health, congratulated the governors upon the mortality in the maternity wards being only 2·8 per 1000, "the lowest in London, and possibly in the whole country."

INTERNATIONAL COÖPERATION IN PUBLIC HEALTH

ITS ACHIEVEMENTS AND PROSPECTS *

BY SIR GEORGE S. BUCHANAN, C.B., M.D., F.R.C.P. Lond.

The International Sanitary Convention, 1926

AFTER the war, as I have already shown, the impulse to establishment of greater confidence between countries was growing, while it had to be realised that the latest convention, though as recent as 1912, now related to a pre-war political geography that was extinct, and to States whose governments as well as whose frontiers had been radically changed. Meanwhile, also, a good deal more had been learned from the war years about international coöperation over infectious diseases, and it was clear that if any general new convention was made it could no longer be limited to cholera, plague, and yellow fever. Several countries had, for example, adopted a policy of their own to control the entry of typhus and small-pox infection at their sea or land frontiers, and action in regard to these two diseases at least required some mutual understanding in the interests of traffic and of rational hygiene. We were in great difficulties also in consequence of the way in which rat plague had spread from port to port by means of shipping, often causing human plague and, in any case, great expense in its eradication. The danger was being met by efficient methods of effectively destroying rats, particularly by cyanide fumigation, but shipping was finding itself in the impossible position of having to submit to deratisation and all the delay and cost that it involved, at one port after another, undertaken merely because the vessel had originally come from an infected country, and without regard to the previous deratisations or fumigations to which she might have been subjected in course of the same voyage. It may well be supposed that when the fumigation of a ship on which there was no evidence of any plague infection was found to cost several hundreds of pounds without producing a single dead rat, the owners became eloquent.

The difficulties of amending the 1912 Convention and adjusting it to new conditions, political and medical, were very great. Nothing could have seemed more contradictory, for example, than the post-war policies of the health services of the United States, Japan, and Great Britain on many of the questions at issue. Indeed, at one time it seemed likely that no new world-wide agreement would be possible, and that the whole matter would have to be left to particular agreements negotiated between countries or to regional agreements. This view was strongly contested by countries like our own with a large world trade, and fortunately with good effect. The convention which at present regulates all these matters—the International Sanitary Convention of Paris, 1926—drawn up by a plenipotentiary conference working on the drafts prepared by the Office International d'Hygiène publique—is world-wide in its application, and was able to be so by its being based on the adoption of new principles of international coöperation. The rat difficulty, for example,

---

* The Milroy Lectures delivered before the Royal College of Physicians of London on Feb. 27th and March 1st, 1934, with a few subsequent additions of detail.

was met with by establishing the now well-known international system under which all ships are liable to examination every six months at designated ports, in order to ascertain whether they are rat-infested and should or should not be deratised. Then, again, the several infections were no longer dealt with collectively but each according to the natural history of the disease. For "infected ship" we substituted "plague-infected ship," cholera-infected ship, and so on. Next, the whole system of intercommunication between countries in regard to the prevalence of infectious diseases was altered. While diplomatic communications were preserved for certain purposes, it was the technical office in Paris which was then made directly responsible for the receipt and dissemination of the necessary information to the health departments of the signatory countries. It was here that the links with the Singapore Bureau and the Pan-American Sanitary Bureau, already described, became important.

The Office International was made responsible also for many other duties, such as the coördination of the sanitary control of the Mecca Pilgrimage, the promotion of subsidiary local agreements, and generally for a continued supervision over the way in which the Convention worked in practice. This function it has fulfilled conscientiously and thoroughly by means of a standing Quarantine Commission which meets during its half-yearly sessions, and gives its opinion for transmission to governments on any anomalies which are brought to its notice and on any matters of practice which are not defined in the Convention but require a common understanding. At recent sessions, for example, the Quarantine Commission has dealt with the standards which should be adopted for the fumigation of ships by cyanide, or sulphur, with the abolition of the aged but unvenerated requirement that ships should carry and produce bills of health in relation to the ports from which they have come, with measures for facilitating direct communication between port medical officers of adjoining countries, with the international codes of flags, signals, and wireless which are required for public health purposes, and many other relative questions. Their findings on these matters are often only arrived at after discussion at two or three sessions, during which the delegates have been in position to ascertain the views of their own governments and consult their experts; but when arrived at they have never to my knowledge been seriously questioned, and are now very widely adopted and govern the ordinary practice of port sanitary authorities

We are, of course, far from having achieved finality by the International Sanitary Convention, 1926, but it may safely be asserted that its prescriptions, when subject to constant practical consideration and revision in the way which is effected in Paris, have within the last few years almost metamorphosed the practice of port sanitary administration for the better. One anomaly after another has been removed, in each case with the object on the one hand of strengthening the national sanitary authorities in their real task of disease prevention, and on the other of saving transport and shipping from useless and unnecessary interference. The Paris Office in this matter has, I believe, come to possess the confidence both of the public health departments and the shipping interests of the maritime countries. All this, I may add, is exemplified in the changes which have been made in our own system of port sanitary administration in the United Kingdom since 1926, during which time we have given close attention at the Ministry of Health and in the Departments of Health for Scotland and Northern Ireland to the equipment and working of our port administration on the lines internationally agreed to. In recently amending and consolidating the port sanitary regulations made under national legislation in the United Kingdom, the various requirements of the Convention have received due recognition. Their working, as I have indicated, is dependent on the system by which the intelligence we obtain about infectious diseases abroad under the terms of the Convention, and also through the activities of the British Consular Service, is classified and made readily and rapidly available to port medical officers of health. This is done in the Medical Intelligence section of the Ministry of Health, chiefly by means of a confidential "Weekly Record," designed by my colleague Colonel S. P. James, which I venture to claim as a model of its kind.

The International Sanitary Convention for Aerial Navigation, 1933

The experience gained in preparing the International Sanitary Convention, 1926, encouraged the Paris Office a little later to take up a proposition originally made by the Italian representative at the time of the Peace Conference—namely, that international rules should be established in respect of the precautions to be taken to prevent the transmission of infectious disease by aircraft. At first sight this object seemed one which could be attained by enunciating a few simple and general principles. While international air-traffic did undoubtedly add a new route by which infection could be carried, the number of passengers was infinitesimal in relation to those going by sea, and, relatively speaking, they were well-to-do and responsible people. The parallel case seemed rather to be that of international journeys by train and road, for which a few simple rules, chiefly in the direction of securing the maximum of liberty and non-interference with merchandise, had sufficed. But it soon became evident that something more was wanted. The opening up of long air routes, from the East in particular, was held by certain countries which are always apprehensive of the importation of cholera—e.g., Egypt or Persia—to require the imposition on arrivals by aircraft of the same measures which had been so lately settled in Paris for arrivals by ship. Thus, passengers coming from infected or suspected countries like India were to be made liable to detention at the aerodrome, say, in Persia or in Egypt, pending the results of bacteriological examination of their stools, and special requirements were being prescribed in respect of place of landing of the aircraft itself and the movement of its crew.

Another and troublesome demand arose for evidence of the health of the places from which the aircraft had come, which took the form of expecting air traffic to be complicated with the same system of bills of health which had proved such an irksome and profitless formality in the case of shipping. In fact, we were up against several of the old questions of unnecessary and irritating measures which were not warranted by the actual risks.

There was, however, another side to it. The introduction of air traffic in certain cases has actually created a new kind of risk of introduction of infection by reason of the rapidity of air flights from distant countries. The public health authorities were within their rights and, indeed, only performing an obvious duty when they were taking measures to protect themselves against these risks. The questions, internationally, were what form the action should take, how to define it in terms of maximum measures, and how to secure a reasonable uniformity which would enable the air lines to know what was expected of them. The case with which we were principally concerned was that of yellow fever, less perhaps in respect of the existing air lines than of those which sooner or later are sure to be established between the yellow fever infected countries in Africa to other parts of that continent. Such lines are already in operation in the New World when the countries of yellow fever prevalence are traversed. The yellow fever danger, in the absence of control, was accordingly represented as being a very formidable one, seeing that all the conditions, including the presence of stegomyia, which promote the spread of yellow fever infection were present in the uninfected eastern part of Africa, and that India and other countries farther to the East, where the same position obtained, had the gravest apprehensions about the introduction by air of a disease which, on account of its natural history and methods of spread, was believed hitherto never to have gained access to their populations.

Fortunately, however, the case was one in which the establishment and observance of an agreed code of action should go a long way to the removal of any legitimate apprehensions on this ground. The key of the position was that the number of aerodromes at which countries permit arrivals from other countries is very small, for customs and political reasons. Hence there are few centres to control and at most of them access to medical services is feasible. So that, given an aerodrome used for international flight which is in a region where yellow fever exists, it is usually quite a practicable thing to keep that aerodrome and its personnel free from infection. And as to mosquitoes, it is fortunately not difficult to secure their destruction in passenger aircraft. And finally, in order to obviate the risk of the flight of passengers who have quite recently been infected and who might be able during the six days thereafter to infect stegomyia in a susceptible country, the problem is no greater than those which are constantly dealt with by any medical officer of health for other diseases. It resolves itself into medical examination and inquiry into recent movements of the passenger at those particular aerodromes where the possibility of yellow fever infection has to be considered—i.e., those which, by reason of the greater euphony of the French name, we have termed "Anti-Amaryl Aerodromes." This can, if need be, be supplemented by observation of the passenger until the end of the six-day period.

By degrees and after several sessions, and always in close consultation with representatives of air navigation, the Committee of the Office found itself therefore in a position to supplement the International Sanitary Convention, 1926, which deals with sea and land transport, by the International Sanitary Convention for Aerial Navigation, which was opened for signature at The Hague in April, 1933, and has already been signed on behalf of many important countries and their possessions. The code is sufficiently comprehensive to be applicable to American air routes, as well as to the Old World; and subject to the completion of a technical reservation, which gives no difficulty, this Convention is to be signed by the United States. It should be added that the Second Pan-American conference of Directors of Health also assisted the Office International by giving consideration and approval to the text.

Looking to the great importance attached to the yellow fever aspect of the question in West Africa and the East, it is satisfactory to note that its universal acceptance by states, dominions, and colonies in the Continent of Africa has already nearly been achieved. For this result, special recognition is due to the initiative of the Government of the Union of South Africa, which secured a conference on this and other subjects at the end of 1932 and went into the question in all its bearings. In this, the coöperation of the Health Organisation of the League of Nations proved most useful, since they not only accepted the request of the Union to convene the conference but also were represented by Dr. Park and myself as Secretary and President respectively.

Other International Health Conventions: the Brussels Agreement, 1924

The international conventions and agreements on health questions which may come before the Paris Office are by no means limited to quarantine. The Royal College of Physicians has a particular interest in one such agreement—that which settles the International List of Causes of Death (which owes much to the help given to the British delegation by our former President, Sir Humphry Rolleston) and has to be related to the Nomenclature of Diseases for which the College is responsible. But as the position of the Paris Office to that agreement is not one of direct responsibility, I will choose another example—namely, the Brussels Agreement of 1924—using a few notes from my colleague, Dr. M. T. Morgan, who in future will represent the United Kingdom on the Permanent Committee of the Paris Office, and has also been included by that committee among its nominees to the Health Committee at Geneva.

Many of us will remember our apprehensions of increase in venereal disease after demobilisation, and especially the fear we had of the introduction of severe types of syphilis from eastern and other foreign countries on the resumption of normal sea traffic. To meet this apprehension special care was taken in the United Kingdom to augment the number and increase the efficiency of our State-subsidised venereal disease clinics, and more than ordinary attention was given to this provision in our seaports. At our venereal disease clinics it has always been the practice to give the same facilities to the foreigner and to the foreign seaman as to our own nationals. But this practice was far from being general or reciprocal in all parts of the world, and we had evidence that in several ports overseas the incidence of venereal disease was very high, and that British seamen were contracting these diseases there without being treated, and were introducing the infection on their return to home ports. In these circumstances I was instructed to raise the question before the Permanent Committee of the Paris Office in the spring of 1920, and the discussions which then began ultimately materialised in an international agreement respecting facilities to be given to merchant seamen for the treatment of venereal diseases, which was signed at Brussels on Dec. 21st, 1924. This agreement, therefore, has been in operation for over nine years. It has been ratified by 16 countries, including some of the principal maritime nations of the world, and received the adherence of 24 Governments, who apply it although they have not gone through the formality of ratification. To these should be added other countries who, rather inconveniently, are not signatory, but conform fairly closely to the scheme of the Agreement. This document consists of seven articles, by which the signatory countries undertake to establish and maintain in each of their principal sea or river ports services for the treatment of venereal disease open to all merchant seamen or watermen without distinction of nationality, such services comprising modern treatment. The supply of medical necessaries, and treatment in hospital should the doctor of the service consider it essential, are to be free of charge, as also are necessary medical supplies to enable treatment to be followed on the voyage to the next port of call.

It is part of the system that each patient receives a card following an official international model which is strictly personal to himself and on which he is designated by a number only. This card records diagnosis, treatment carried out at the various centres, and the results of serological and other special examinations. Masters of ships and shipowners are to make known to the crews the existence of the services, and similar action is to be taken by port sanitary authorities. A list of the ports at which the system is working was lately published by the Paris Office and covers some 750 seaports. At the instance of the Ministry of Health this list of centres at ports at home and abroad has been distributed to our own port clinics for venereal diseases, and, through the instrumentality of the Board of Trade and shipowners, copies are also made available to seamen on British ships.

The whole system has worked well and there can be no doubt that it has not only done a good deal for the merchant seaman himself, but has checked the spread of infection among the population generally. The Paris Office last year made inquiries of all the Governments concerned in regard to the practical working of this agreement and the directions in which improvements might be desirable. It was clear from the replies that the international system is by now well known to sailors, who frequently ask for information about these centres and expect to obtain treatment there. At certain ports, however, some additional measures are needed to make the facilities better known. At other ports arrangements still have to be made for the relatively rare cases in which it is necessary to detain the seaman in hospital. Experience also suggests that certain alterations in the form of the seaman's personal card would be useful. All these details are now receiving fresh attention; I draw attention to them as an example of the special advantage of the Paris Office as a means of securing that international agreements and conventions are duly applied in practice, or revised when experience brings out some new factor which had not been taken into account when the agreement was made. There are, I believe, many international agreements on other subjects which would be in a healthier state if this principle was applied to them.

General Work of the Office International d'Hygiène Publique

It can hardly be supposed that the delegates from the health departments of over 50 countries could meet for ten days in the spring and again in the autumn and limit themselves to discussing the terms of diplomatic agreements and supervision of their application, however necessary these things may be. The fascination—I use the word advisedly—of these meetings is the use of them which has grown up, particularly under the guidance of our late President, M. Velghe, to communicate and exchange information about the particular happenings which are troubling a particular country to-day, but may well affect its neighbour to-morrow, or of which another neighbour may have special experience. One introduces, for example, the characteristics of the small-pox we have had epidemic in England during recent years; with its copious rash and classic beginnings fading off almost without fever, pustulation or pitting, and with a practically negligible mortality even in the unvaccinated. This brings out experience of "alastrim" elsewhere; it leads after one or two sessions to an understanding of the nature and geographical extent of what we now agree to call "variola minor," to the understanding that it can coexist with variola major, and presently to the adoption of these two terms in official nomenclature—incidentally to our own great convenience, administratively, in this country. We got these conclusions in this particular case because one member of the Committee, Prof. Ricardo Jorge of Lisbon, was willing to give his time and unrivalled epidemiological acumen to a survey of the world data, and prepare a report for us. Prof. Jorge has rendered us many such services, as have Dr. Jitta, Dr. Lutratio, Dr. Hamel, Dr. Tsurumi, the late Prof. Cantacuzène, and the representatives of the French and Belgian Colonial health services—it is, indeed, invidious to mention names, since one member after another takes up the particular burden for the common good. *Proximus ardet*; when Dr. Madsen tells us of epidemic myalgia, under the name of "Bornholm disease," in Denmark, we start looking for it in other Scandinavian countries, or in Poland, in Germany or England, and bring the results to the next session. The early inquiry into undulant fever in England, made for the Ministry of Health by Sir W. Dalrymple-Champneys in 1929, was the result of communications which I brought home from Paris, which showed how necessary it was to look out for this disease in Northern Europe. There have been many such.

Sometimes common action needs to be concerted between delegates although a formal agreement is recognised to be undesirable—this has been the case with the European prohibition of the importation of parrots since the psittacosis of 1929–30. If we were to stop the movements of parrots from country to country—and it was necessary—we had to act together in Europe. In this country we were at first some weeks behind other countries, and were running a definite risk of being swamped by possibly infected parrots which were denied their usual markets on the Continent. I hope that the European countries will continue to pool all their information on this subject if the Paris Office should recommend—the matter is not yet settled—that universal prohibition is no longer necessary; unfortunately it is not only with parrots that the removal of a restriction is more difficult than its original imposition.

I should end my note about the work of the International Office of Public Health in Paris by a reference to the review of its 25 years of activity, presented to us by the Director of the Office in October.[1] For all the work I have described and for much more we depend on the Director of the Office, Dr. Abt, and his deputy, M. Marignac, and the small competent personnel through whom all the regular intelligence functions of the Office under the Conventions are carried out. They have also the really considerable credit of that unique monthly publication, the Bulletin Mensuel de l'Office International d'Hygiène publique. This bulletin is authoritative as regards public health laws and regulations in different countries ; it now reproduces all the chief contributions made or presented by the delegates at the sessions, and adds abstracts and reviews selected for their international value.

---

[1] Vingt-cinq ans d'activité de l'office international d'Hygiène publique, 1909–33. Par Dr. Georges Abt. Published at 195, Boulevard St. Germain. 1933.

A word must also be said here to recognise the accuracy with which this small staff deals with documents in many languages and presents them in the official language of the Office, which is French. This goes far, though obviously not far enough for English-speaking people, to compensate for the absence from our Paris meetings of the bilingual system of the League of Nations, in which there are two official languages—French and English. An English edition of the Bulletin Mensuel, if funds allowed, would certainly be of very great advantage.

Some Concluding Observations on the *International Health Organisations,* and British *participation*

I feel, in conclusion, that, notwithstanding the description I have given of the working of the organisations at Geneva and at Paris, I may still be asked a familiar question—namely, whether it is necessary that public health and medical work which is so essentially dependent on Governments and their Health Departments, should continue to be conducted in two capitals by two committees and two secretariats.

Another occasion must be taken to discuss the advantages and disadvantages of reviving and revising the Assembly project of Dec., 1920, mentioned at the beginning of these lectures—taking account of the special lines on which each of these international organs has developed, and the strength which each of them has gained, since that date. New international discussions and new conclusions on this subject will be required sooner or later. But meanwhile, from the point of view of those who participate in the work, the duplication, such as it is, gives relatively little trouble. And the advantages of the two organs functioning side by side each in the directions which I have mentioned are so great, that it is hardly desirable to raise constitutional questions about their mutual relationship unless or until some new and strong reason arises to disturb the present order of things. Objections may be made to the scheme of creation which gives us a left hand as well as a right, and there are occasional drawbacks from the right hand not knowing what the left is doing. At the same time it is our general experience that, given a good directing brain, we get on with two hands better than with one.

There are in this connexion some *imperial and domestic considerations* worth a moment's further review. No one could take part, as I have done, in the many official conferences, in the preparation of international conventions, or in the discussions at these international health offices, without realising how naturally they come to assist the mutual understanding and helpfulness of the English-speaking peoples, and here, with experience of the way in which the great public health service of the United States, under the epoch-making direction of Surgeon-General Cumming, has responded to every call for international effort, it is right to add the U.S.A. and the British Commonwealth of Nations together. It is not that the English-speaking peoples combine against those of Latin or other nationalities—in several ways the American and Australian methods are much closer to those of other countries than they are to the United Kingdom—but it comes about from the language, and also the [illegible] basic traditions of health [illegible] and medical practice.

Australia, Canada, New Zealand, the Union of South Africa, the Irish Free State, the Sudan, are all countries which adhere to the Rome Convention, 1907, and are represented by their own delegates at the Paris Office. In one or two cases where distance makes it inconvenient for the Dominion to send a representative from its health service, the Ministry of Health has been invited to permit one of its medical officers to act for and report to the Dominion Government. This practice has been found mutually convenient, particularly as it has put at the disposal of the Office International medical officers with such special experience as is possessed by my colleagues, Colonel S. P. James, the representative of New Zealand, on all tropical medicine questions, and by Colonel P. G. Stock (who was formerly Director of Medical Services in South Africa) on matters of quarantine.

Indian participation again has from the first been of great importance, seeing that it is on Indian information that we have so much to rely when we are dealing with major epidemic diseases such as cholera, plague, and severe small-pox. Until 1929 there was no separate representation for the British colonies, but the creation of the office of Medical Adviser at the Colonial Office naturally carried with it direct representation of the colonies by Dr. Stanton, which has since been continued. The results of the international work are now communicated to the public health services of practically all British colonies and dependencies and countries under British mandate, and every endeavour is made to bring British colonial problems which would help or benefit from international discussion before the Paris Committee—an endeavour which corresponds with that of the numerous colonial and overseas possessions of other countries, notably France, Belgium, and Holland. The coördination or mutual understanding of health work between adjoining colonies of different nationalities, which is so often needed, particularly in Africa, can thus be helped centrally as well as locally. On the League of Nations Health Committee also, though British Empire representation is less complete, the Indian Medical Service has been represented almost from the beginning, while most of the Dominions at one time or another have had a member drawn from their health services.

It is thus not difficult to understand how these international meetings bring together the public health services of the English-speaking nations in a way which would not otherwise be achieved. We come almost of necessity to establish a personal relationship with fellow-workers overseas which is invaluable as a time-saver when dealing with common problems.

One might even go further in enumerating the advantages of international coöperation by referring to our domestic arrangements. British representation at, and the chief work connected with, these offices naturally falls on the Ministry of Health. In this respect that Ministry inherits, through the Local Government Board, the traditions of the medical department of the Privy Council. It is to the Ministry of Health, and its medical service, that the home Government looks in the first instance for advice on questions of health policy affecting its relations with foreign countries, and through the Ministry that necessary liaisons with other departments are maintained.

But representation of His Majesty's Government in administrative matters concerning health naturally entails consultation by the Ministry of Health with many other government offices at all stages, and the making of reports which have to go to many different quarters if the representative is properly to do his business; in particular, if we are to pull our weight, the association with the Medical Research Council and its many committees and research workers must be specially close. In all these matters, what is done through these official international health offices is only half done if it is just treated as belonging to a remote corner of some one department, labelled "international," and only remembered, if at all, when a difficulty has arisen.

A delegate or member of these international committees develops, of course, a kind of special sense as to the administrative bearings of the questions with which they deal, and he may bring to the international council a special personal competence on some one subject on which he is an authority. But for most things he asks for nothing better than the position of a trusted intermediary. As an agent, he wishes to occupy a normal place in the national public health machinery, he wants others to feed him—even to overfeed him—with material to take to and bring back from the international sessions and discussions. The pleasure of the work—and I have found it a great pleasure—is its measure of the confidence and willing help of one's colleagues, in one's own department, and in all sections of the public service, given for the common benefit.

I should refer in this connexion to a useful practice by which the programme of work at Geneva and Paris is communicated to and discussed generally at the Ministry of Health with medical officers from the Medical Research Council, the Departments of Health for Scotland and for Northern Ireland, and the British Colonies, by means of a medical committee over which my colleague, Dr. T. Carnwath, now presides. The helpfulness of this arrangement can hardly be exaggerated, particularly since the ultimate output needs to be dealt with also in the same way. I must add also a word about the value of our consultations with the London School of Hygiene and Tropical Medicine, which itself has been placed in direct association with the Medical Director and Health Section at Geneva for a number of purposes, including, as I explained above, the arrangements for the reception and guidance of visitors from overseas who desire to study particular British questions. As the work which I have described goes on from strength to strength, as I think it must do, other means may be devised by which its nature and results become more used and better known than they are at present by public health officers and the medical profession generally, for example, by securing some closer association of them by our great medical colleges and universities.

HEY'S DISLOCATION

By J. W. Riddoch, *M.C.*, M.B., F.R.C.S. Edin.

HON. SURGEON, MIDLAND HOSPITAL, BIRMINGHAM

Posterior dislocation of the proximal phalanx at the metacarpo-phalangeal joint of the thumb has drawn on itself a certain amount of notoriety owing to the fact that it is frequently impossible to reduce by ordinary manipulation. There have been several factors put forward as the cause or causes of this difficulty in reduction, such as :—

1. The head of the metacarpal being caught between (*a*) the flexor pollicis brevis and the adductor pollicis; (*b*) the two heads of the flexor pollicis brevis.
2. The tendon of the flexor pollicis longus winding itself round the neck of the metacarpal.
3. The volar accessory ligament being torn from its proximal attachment to the metacarpal, and being interposed between the bones.

The last-mentioned factor finds most general acceptance and the treatment recommended is the tenotomising of the volar accessory ligament through a puncture on the dorsal aspect of the joint.

A CASE DESCRIBED

A recent case is of interest as it was dealt with by open operation.

J. W., a girl of 7, was admitted to hospital on Sept. 2nd, 1933, after falling on the right hand. Reduction was attempted under an anæsthetic in the casualty department, but failed. On the 4th another anæsthetic was given and attempted reduction was again unsuccessful. A posterior incision was then made on the radial side of the extensor tendons and the joint opened. The dislocation of the phalanx was typical, the displacement being towards the ulnar side as well as backwards.

The volar accessory ligament had been torn from its proximal attachment and passed backwards over the base of the phalanx, its free end lying in the posterior part of the joint. Manipulation with the joint open failed, but when the ligament was pushed forward the dislocation was easily reduced, and showed no tendency to redisplacement. When the dislocation was reproduced the ligament again passed back between the joint surfaces.

REMARKS

Assuming, as is the general opinion, that the mechanism demonstrated above is the cause of the difficulty in these cases, I find it difficult to understand how tenotomy can be carried out without doing damage to structures in front of the joint, if indeed it can be carried out at all on a structure which is not on the stretch. The tenotome would have to be used fairly forcibly to be sure of piercing the volar ligament, and it would be very liable to penetrate the long flexor of the thumb. Probably the essential happening, when this procedure is carried out, is that the ligament is pushed forward out of the way, and this enables reduction to be carried out by manipulation.

In view of the damage that is liable to be done to the joint surfaces as well as other structures by a sharp instrument, it would probably be better to confine the use of the tenotome to the opening of the joint, and then to introduce some blunt instrument such as the flattened end of a Cheyne's dissector to push forward the ligament preparatory to manipulation.

Bath Mineral Water Hospital.—Last year there were 1115 admissions. This is a small decrease due, the annual report thinks, to the increased facilities in many towns, especially in London, for the outpatient treatment of rheumatism in its early stages. Each patient stayed on an average 43·2 days. The establishment of a school of massage is under consideration.

DIABETES MELLITUS IN CHILDREN

By Leslie Cole, M.D. Camb., F.R.C.P. Lond.
PHYSICIAN TO ADDENBROOKE'S HOSPITAL, CAMBRIDGE;
UNIVERSITY TEACHER IN MEDICINE

(*Concluded from p. 950.*)

TREATMENT

Method of standardisation.—All patients are admitted to hospital as soon as possible after the diagnosis has been made and usually on the day of their first attendance. Starvation or severe restriction of diet have not been employed, except in the cases which were admitted before 1927. On admission, patients have usually been placed on a diet containing one-third to one-half of the caloric requirements for the age, the carbohydrate not exceeding 40 g. Lawrence's[16] line ration scheme (5-gramme carbohydrate lines) is used in arranging this diet. In most patients a small dose of insulin is given from the start, and this is gradually increased until the 24-hourly specimen of urine is sugar-free and the blood-sugar is within normal limits. This takes from one to four weeks and during this time the patient is kept entirely in bed. During this period any focal sepsis is treated if the patient is sufficiently fit. When the blood-sugar is consistently normal and the urine is sugar-free, the diet and insulin are increased gradually. The carbohydrate has not, as a rule, been increased at this stage to more than 80–100 g. During this stage the patient is allowed to get up. When the blood-sugar is consistently normal and the 24-hourly specimen is sugar-free on the fuller diet the patient is encouraged to be as active as possible about the ward, and if any slight symptoms of hypoglycæmia develop or the blood-sugar readings are consistently too low, the dose of insulin is reduced. Before discharge the insulin is reduced slightly because when children are leading a more active life at home they almost always require less insulin than in hospital. If septic foci have been eradicated at the beginning of treatment a greater reduction is made to allow for the late recovery from the effects of sepsis on the islet tissue. Even with this reduction it is sometimes found that further reduction of the dose is required during the first few months as an out-patient. Patients are usually kept in hospital for from one to two months. To shorten this period is undesirable and usually leads to more difficulty later on and the necessity for readmission. In hospital the details and working of the diet are explained to the parents and they are taught to measure and inject insulin. Children over 10 who are sufficiently intelligent are taught to measure and inject their own insulin. Some are taught to test their own urine for sugar.

After discharge they attend as out-patients every two months. Urines are tested and blood-sugar is estimated, and adjustments made in diet and insulin. Patients who are now taking more than 100 g. of carbohydrate have had the additional amount added during the last three years, usually after they have been taking the lower amount for a year or more. In a few of the more recent cases higher figures have been given (Cases 3, 7, 16, and 18) after the first month of treatment, but it is still too early to say how far this is satisfactory. One of these developed an infection after six months and the diet has since had to be reduced.

Energy requirements.—Adults require food for maintenance and activity. Children require in addition food for growth and to compensate for their relatively greater heat loss. This additional requirement is large. Lawrence's figures for normal children of different ages are as follows:—

Under 1 year	100	calories per kg.	6– 9 years	70–60	calories per kg.
1–2 years	90–80		10–13 years	60–50	
2–5 years	80–70		14–17 years	50–40	

Although the aim has been to give diets approximating to the normal in order to ensure normal growth and activity, this is often difficult, owing to the severity of the disease in children, even if a very large dose of insulin is given. In most of the more severe cases it has proved impossible, or inadvisable, to give the theoretical caloric requirement either because the disease is so severe that with such a diet it is impossible to keep the blood-sugar even near the normal limits or because children have been growing and living normally on a low diet and have been definitely less fit when it was increased. In these latter it is remarkable how nearly normal they have remained both in growth and activity.

The relative proportions of protein, fat, and carbohydrate in the diet is a subject upon which different views are held. At one end of the scale the ratio of ketogenic and antiketogenic substances is determined[17] by the formula $F = 2C + \frac{1}{2}P$. The advent of insulin however made it at once possible to give a more liberal allowance of carbohydrate. Of recent years good results have been obtained with a far higher proportion than had previously been thought possible. Rabinowitch[18] showed that in a series of cases a diet such as C. 50, P. 50, F. 150 (1750 calories) could be changed to one of C. 236, P. 73, F. 56 (1736 calories). In seven out of ten cases the change made a reduction of insulin possible. Short,[19] Poulton,[20] and others have also used diets of this type and for the comparatively short period for which they have been tried have found them satisfactory. The diabetic is able to tolerate these larger amounts of carbohydrate probably because of their stimulating action on the secretion of insulin by the remaining healthy islet tissue. Macleod[21] has shown that in healthy human subjects a greater fall of blood-sugar follows small doses of insulin plus glucose than follows the same amount of insulin alone. How exactly this is brought about is not yet quite clear, but from the evidence afforded by cross-circulation experiments he considers that the secretory activity of the islet tissue is under the control of the vagus centre and that this is stimulated by an increased concentration of glucose in the blood.

In most of the cases recorded above the carbohydrate has been increased during the last three years in amounts varying between 30 and 60 g. and in some there has also been a reduction in fat. The results have been generally satisfactory, particularly in that the patients have felt fitter and have been less liable to mild attacks of hypoglycæmia. To attain this increase no corresponding increase in insulin has been necessary in the less severe cases. In the very severe cases of long duration (such as Cases 2, 4, 5, and 6) it has not been found possible to increase the carbohydrate above 110 g. In the milder cases the diet can be varied considerably on the same dose of insulin without any corresponding change being observed in the blood-sugar readings or urine analyses.

In practice no hard-and-fast rule has been followed either as to the total calories given or the relative proportions of the different elements. The figures given by Lawrence for total caloric requirements have been used as a rough guide only, being modified according to the requirements and progress of the individual. The amount of carbohydrate has been varied according to the severity of the case, the stability of the blood and urine findings, the liability to hypoglycæmia and the sense of well-being, activity, and growth of the patient. Broadly speaking, all these considerations are best met with a diet containing between 90 and 110 g. of carbohydrate in very severe cases and between 120 and 200 g. in less severe ones.

PROGRESS

The progress of the disease is very difficult to estimate and this is particularly so in children whose food requirements are constantly changing. Infections too are a very disturbing factor in estimating progress. A mild infection such as a slight cold or an infected tooth undoubtedly has a considerable effect on the efficiency of the remaining islet tissue. If standardisation of diet and insulin is carried out with such infection present or before the results of an infection have quite passed off there may be considerable apparent improvement when such effects do pass off.

Case 7 shows this early recovery very clearly.

On admission he was on the verge of coma. He had had symptoms of diabetes for a few weeks and had scalded his foot four days before admission. The scald was a slight one and did not appear to be septic, and there was no evidence of any other infection. His blood-sugar was 0·4. In the first 24 hours he received fluids containing 80 g. of glucose and 85 units of insulin. His progress is seen in Table I.

TABLE I.—*Treatment in Case 7*

Diet.—April 14th to 17th: Fluids; 60 g. glucose. April 18th to May 24th: C. 80, P. 60, F. 120.

Date in 1933.	Units insulin.	Urine (24 hr.). Sugar (no acetone).	Blood-sugar.	Date in 1933.	Units insulin.	Urine (24 hr.). Sugar (no acetone).	Blood-sugar.
April				April			
14	60	+	0·11	30–			
15	30	0	..	May			
16	36	+	..	2	30	T.	..
17	36	+	0·16	3	20	0	0·04

19	45	+	..				
20	40	+	0·08	11	20	0	(6 A.M.) 0·14 0·09
21–24	40	+	..				
25	40	+	0·13	13	20	0	0·08
27	40	+	(6 A.M.) 0·18	15	10	0	..
			(10 A.M.) 0·06	17	10	0	0·07
28	40	0	0·06	20	N.	0	0·08
29	40	0	0·06	24	N.	0	0·09

N. = none. T. = trace.

This patient was finally sent out on C. 200, P. 60, F. 80, and 20 units daily. On this his resting blood-sugar has remained below 0·1, and his 24-hourly specimen has not contained more than a slight trace of sugar.

This patient might have been standardised on a smaller amount of carbohydrate and no insulin, but he is probably safer on a larger diet and this dose of insulin if he develops any infection. The liability of children to sudden increased loss of tolerance when an infection develops makes treatment without insulin, even in mild cases, extremely risky, and it should never be attempted.

Case 8 is another example of early improvement.

In March 1931 this patient was admitted on the verge of coma and was standardised on C. 45, P. 45, and F. 90, and 15 and 10 units of insulin daily. At this time three very septic teeth were removed. During the next six months the insulin was steadily reduced on account of hypoglycæmic attacks and in August it was stopped entirely. In September he had a relapse and began to pass sugar again, and was readmitted in October with a blood-sugar of 0·26. He was discharged on a diet of C. 85, P. 60, F. 110, and 12 units of insulin twice a day, which during the next few months was reduced to 11 units b.d. In May 1933 the diet was again increased to C. 160, P. 72, F. 120, and no further increase of insulin was found to be necessary, the urine remaining sugar-free, and on nearly all occasions the blood-sugar within normal limits. In this case the great recovery during the first six months of treatment was probably partly due to the beneficial effects of insulin and partly to the removal of focal sepsis.

If every infection could be treated under hospital conditions its effects might be less, but unfortunately in this series this has often not been possible. The following are examples of the progress of the disease:—

Case 12.—Three weeks after the first symptoms appeared the resting blood-sugar was 0·26 per cent. (For further details, see case notes.) She was then standardised on a diet of carbohydrate 85, protein 45, and fat 90, and six units of insulin twice a day. During the next 18 months the resting blood-sugar varied between 0·04 and 0·12 (one reading of 0·18 per cent.). The 24-hourly specimen was generally sugar-free, but occasionally showed a trace of sugar. To maintain the blood-sugar at this level the insulin had to be increased gradually to 10 units twice a day. At the end of this period she developed a severe cold with bronchitis, and for a short time had a high blood-sugar, glycosuria, and severe ketosis. At the age of 5 she was readmitted and restandardised on a diet of C. 90, P. 50, and F. 45 (on account of ketosis), and 24 units of insulin daily. This child is now 7 and, although the diet has been increased to C. 110, P. 60, and F. 120, she still only needs the same dose of insulin to keep the blood-sugar between 0·03 and 0·09 per cent. Her progress may be tabulated as follows:—

	Diet.	Insulin.	Weight.
Age 3.	C. 85, P. 45, F. 90, Cal. 1400	6 b.d.–10 b.d.	.. 1 st. 11 lb.
„ 4½.	Infection with severe relapse of diabetes.		
„ 5.	C. 90, P. 50, F. 45, Cal. 965	12 b.d.	.. 2 st. 9 lb.
„ 7.	C. 110, P. 60, F. 120, Cal. 1800	12 b.d.	.. 3 st. 5 lb.

Case 9, after she had been treated for 18 months, was standardised at the age of 9 on C. 90, P. 56, F. 105, Cal. 1575, and 25 and 20 units of insulin daily. Weight 4 st. At the age of 11 she was taking C. 102, P. 60, F. 105, Cal. 1640, and 20 units of insulin twice a day. Weight 5 st. 3 lb.

Progress may be summarised as follows. The onset of symptoms is acute over a period of a few days or weeks. Sometimes the parents think they can state accurately the day on which the symptoms began. How long the disease may be latent before symptoms appear it is difficult to say. Within a few days or weeks of the onset of symptoms there is a great degree of impaired sugar tolerance and ketosis, which is often made very much greater by the development of an infection. If the disease is then controlled with diet and insulin there is considerable improvement of carbohydrate tolerance, and if there happens to be an infection present and this subsides or a septic focus is removed there is even more improvement. This improvement is particularly marked if treatment is begun soon after the onset. After one or two years of insulin treatment, although it is often possible to increase the diet with growth and increase the amount of carbohydrate given without increasing the insulin, there does not seem to be recovery in any of these cases to the extent that insulin can be stopped or even reduced very much. On the other hand, the occurrence of further infections or of failure to control the disease with insulin usually leads to further permanent loss of tolerance.

INFLUENCE OF INFECTIONS

The severe effects of acute or chronic infection in the course of the disease are well known, and their frequency in childhood makes management more difficult than in the adult. In the present series this has been shown again and again. Every severe exacerbation in an established diabetic was associated with some infection, and the rise in blood- and urine-sugar and ketosis with even a slight cold is remarkable. This effect is well shown by Case 13 who, while in hospital, developed an acute bronchitis of moderate severity (see Figure) and by Case 16.

An acute infection is nearly always the cause of diabetic coma. The risk, however, of coma developing in a diabetic child is comparatively slight, provided that the dose of insulin is not reduced. Chronic infections as in adults also have a bad effect on the disease and it is of the utmost importance that, if these are present, they should be dealt with early in treatment. It should be remembered that the effect of infection probably persists for some considerable time after it has apparently subsided or a focus has been eradicated, and allowance made for this during standardisation.

BLOOD-SUGAR DURING TREATMENT

An increased amount of glucose in the blood is a stimulus to the secretion of insulin, and in order that what remains of normal islet tissue may not be over-stimulated the blood-sugar should be kept within normal limits all the time. In children this ideal is difficult to achieve, particularly if the doses of insulin are limited to two daily, because the blood-sugar level is controlled by so many variable factors. These are chiefly activity and infections. There is also the variation in strength of different samples of insulin and apart from gross diet delinquences, the slighter variations which must inevitably occur, at any rate in out-patients of this class. Even when children are under strict supervision in hospital there is often an unaccountable variation in the blood-sugar, and this is usually most marked in children during the early months of insulin treatment. In the more severe cases it is difficult to prevent a rise of blood-sugar in the early hours of the morning before the first dose of insulin is given.

Blood-sugars of out-patients are taken between two and three hours after breakfast, and in most this reading can be kept within the limits of normal (0·06–0·12). Apart from the incidence of infections many children remain steady year after year. In others the story is very different, and to steer a course between hypoglycæmic attacks on the one hand, and readings of 0·2 per cent. on the other, seems impossible. This cannot be entirely attributed to carelessness over diet and insulin for it occurs with patients in hospital under strict supervision. Case 13, after being an in-patient on a constant diet and insulin dosage for three weeks, had the following blood-sugar readings on six successive days, two hours after breakfast: 0·04, 0·05, 0·22, 0·15, 0·25, and 0·07. In some patients in whom control is difficult the choice lies between a very strict régime with rather curtailed activities and a normal blood-sugar and no glycosuria; and a normal life with a fuller diet, a raised blood-sugar, and frequent glycosuria. In such a case, I think the latter course is preferable. Patients often feel and appear very much better on a freer diet, even though it means occasional glycosuria and a raised blood-sugar. The risk is that the effects of a raised blood-sugar on such processes as arterio-sclerosis and cataract are not yet known.

GLYCOSURIA DURING TREATMENT

In these patients the aim has been to keep the 24-hourly specimen completely free from sugar. This ideal has rarely been attained. Many patients pass only an occasional slight trace of sugar and remain sugar-free for long periods, in others the urine frequently contains small amounts of sugar. The latter are usually sugar-free after the first dose of insulin in the morning until late at night or early in the following morning when the pre-insulin rise in the blood-sugar occurs. A few cases are still more difficult and at times pass considerable amounts of sugar at other periods of the day. Here again, if they feel perfectly well and are able to live a normal life as is usually the case, a more limited diet and a stricter régime are avoided.

HYPOGLYCÆMIA

Wauchope[22] says: "The point at which hypoglycæmia begins is even more difficult to determine than the normal level; it is indeed not a point but an elastic zone." She suggests the following figures for adults: normal fasting blood-sugar 0·1, symptoms of hypoglycæmia at about 0·08, these become severe at 0·05 and death may occur in the neighbourhood of 0·025. The figures are probably lower in children. Harrison[23] estimated the blood-sugar in a number of children under 12 years of age, and in 11 of these it was below 0·05 on 28 occasions without symptoms, and the lowest value was 0·028. In this series none of the cases was actually observed in coma. Readings of 0·04 were, however, often seen in children with no symptoms, the lowest without symptoms being 0·035. The early symptoms in children are very likely to be missed, for even adults find them very difficult to describe. Wauchope says that children often become pale and tearful, often they are merely naughty or perverse. They may fly into a sudden rage, scream and kick, and refuse obstinately whatever is suggested. They are more prone to develop convulsions than adults. The actual coma is liable to be mistaken for natural sleep. In these, the early symptoms were usually very indefinite and included such complaints as irritability, inexplicable crying, pallor, flushing, hunger, and perspiration. Diagnosis usually depended on the time of onset in relation to the dose of insulin and a careful history as to food and exercise. In the more severe attacks coma usually developed without much warning. Convulsions occurred five times in nine cases of coma. There were no fatal cases, in spite of the fact that in most, medical aid was not available at the time and no treatment was given until the patient began to come round, in some cases after two or three hours, and could take sugar by the mouth. Very few fatal cases in children appear to have been recorded.

Hypoglycæmia occurred most commonly during the first year of insulin treatment and usually resulted from a patient being discharged on too high a dose of insulin. The causes of this in these patients appeared to be three: failure to allow for the effects of exercise; too rapid standardisation and failure to allow for the initial improvement in carbohydrate tolerance; and failure to allow for the improvement of carbohydrate tolerance following the removal of a septic focus.

Lawrence[24] has shown the effects of exercise in lowering the blood-sugar. If too little exercise is given in hospital during the later stages of treatment, when the child goes home and resumes a normal life the dose of insulin is too high, the blood-sugar is lowered, and the carbohydrate reserves are depleted. If standardisation is carried out too rapidly there may be considerable recovery in tolerance after discharge from hospital so that the dose of insulin becomes too high and hypoglycæmia develops suddenly before this is realised. If standardisation is carried out after the removal of some septic focus or while the effects of some latent infection are still present, the patient requires a much larger dose of insulin than is the case later when these effects have passed off, with the result that hypoglycæmic coma develops some weeks after discharge.

The condition can in most cases be avoided if the patient is watched carefully, particularly during the first few months after discharge, but when patients are only able to attend hospital at intervals of a month or two months adjustments of insulin dosage are not always carried out. Other cases are due to carelessness, such as the omission of a meal after insulin or an overdose.

Great instability of the blood-sugar readings occasionally occurs and has already been mentioned. When this is present hypoglycæmic attacks may be troublesome. Brucke [25] describes a child of 8 who had seven severe hypoglycæmic attacks in less than a month although diet and insulin were under strict supervision, and Heimann-Trosien and Hirsch-Kauffmann [26] another in which extreme variations in the blood-sugar readings occurred with no clear explanation. Wauchope emphasises that after manifestations of hypoglycæmia, however slight, insulin should be discontinued or reduced and guarded by abundant carbohydrate until the balance is re-established; she considers that the last course is probably the best because it promotes replenishment of glycogen stores.

DIABETIC COMA

In this series diabetic coma occurred six times in four patients. Two of these were cases of acute coma in which the diagnosis of diabetes had not previously been made and no treatment had been given. One of these was fatal. In four cases coma occurred as a result of infections during the course of the disease, and in three of these it was caused by the usual dose of insulin being stopped because the child was ill. One of these died in coma. In the fourth, the patient developed an acute empyema of antrum, and, although the usual dose of insulin (20 units b.d.) was continued, coma developed. Recovery was rapid with a small extra dose of insulin. Both the cases who died were in extremis when they were admitted to hospital with prolonged coma and dehydration. They had neither been given any insulin for the coma.

Apart from the two cases of initial coma only one occurred in this series, which covers 60 diabetic years, which might not have been prevented by continuation of the usual dose of insulin. The case in which insulin had been continued proved extremely easy to treat.

Of the treatment of a diabetic child during an infection Joslin [15] says :—

> "Do not omit insulin but rather give it more frequently adjusting the dose to keep the urine sugar free or nearly so. Presumably it will be necessary to increase the insulin one-half or even to double it, but if it is given at six- or four-hourly intervals there is little danger of an insulin reaction. With care a diabetic child will pass through any sort of infection which a normal child will withstand."

Unfortunately, fear of hypoglycæmia is still one of the causes of coma. The danger of the former during an infection is, however, slight, and in cases of real doubt can be made still less by giving fluids containing plenty of glucose. The Figure shows clearly the way in which the blood-sugar rises during an infection, even though the amount of carbohydrate given is diminished and the dose of insulin increased. This child was extremely sensitive to infections and eventually died in coma when insulin was stopped during a cold.

GROWTH ACTIVITY AND SEXUAL DEVELOPMENT

An important test of the efficiency of treatment is the *growth* and development. Table II. shows the present height and weight of the 16 surviving patients here described :—

TABLE II.—*Showing Height and Weight of 16 Surviving Patients*

Case	Sex.	Duration of diabetes in years.	Age now.	Weight* now.		Average for age.		Height* now.		Average for age.

18	M.	½	9½	5	0	4	8	4	8	4	4¾

* Without shoes, with clothes.
† Congenital heart disease.

Case 11 is grossly undergrown, but he has severe congenital heart disease. Cases 7 and 18 have only had diabetes for six months. Of the remaining 13 cases, five are underweight, one is of average weight, and seven are overweight. Two are over average height, five are of average height, three are 1 in. or less under the average, and three are 2¾ in., 2 in., and 1½ in. under the average respectively. The physique of all except Case 11 compares very favourably with that of other children of the same age and class. None of the patients have the puffy myxœdematous appearance seen in patients taking insulin.

Activity.—The activity of these patients is not restricted in any way. Those who are still of school age attend regularly and do not appear to catch more infections than normal children. In intelligence they seem to be rather above the average. Case 4, who is now 13 and one of the worst diabetics in the series, and has had the disease since he was 7, has played all games, including football and swimming for several years, is top of his class, and sings in a college choir.

Sexual development.—(Males). Case 2, aged 21, has had very severe diabetes for eight years and is quite normal in development and function. The five other males between 13 and 16 appear to be developing normally. (Females). The five females between 15 and 21 have all developed normally. Three of these aged 15, 17, and 18, who have had diabetes for 8, 5, and 7 years have never had any

Dr. Robert Helig Library
S. M. S. Medical College
No. 33319

menstrual periods. Case 15, who is now 21, and has had the disease for seven years, had no periods until she was 20, and has had three since. Case 5 started normal periods at the age of 14 and these ceased when she developed diabetes at 14½. After six months' insulin treatment they returned and have continued irregularly since but getting more regular.

Joslin [15] states: "The normal sexual development of a diabetic child at puberty may soon be considered as an index of good or bad treatment." In considering the above results however it should be remembered that in those cases with a longer duration than five years insulin treatment was often insufficient to control the disease and the diet was often very restricted.

In conclusion, I should like to thank Dr. C. E. G. Wolf and the staff of the biochemical laboratory at Addenbrooke's for their investigations, Dr. G. S. Haynes. Dr. J. F. Gaskell, and Dr. C. H. Whittle for sending me cases, and Miss J. I. Mills for help in arranging diets.

PLEURO-PULMONARY PERFORATIONS

THE USE OF GAS ANALYSIS IN THEIR DIAGNOSIS*

By C. Allan Birch, M.D. Liverp., M.R.C.P. Lond., D.P.H.

LATE SENIOR MEDICAL REGISTRAR, ROYAL INFIRMARY, LIVERPOOL, AND DOROTHY TEMPLE CROSS TRAVELLING FELLOW

The methods ordinarily employed in the diagnosis of the presence of a communication between the pleural space and the lung may be summarised as follows:—

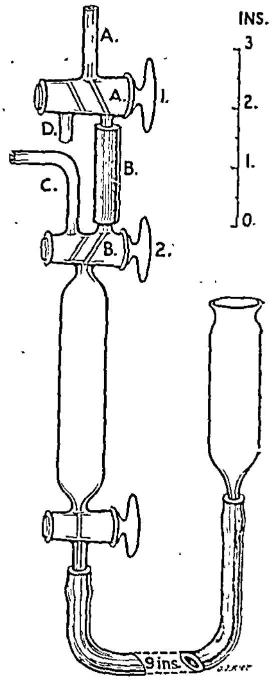
1. *Clinical.*—If a patient known to have an empyema suddenly coughs up a large amount of pus, or if a complete spontaneous pneumothorax develops, the presence of a pleuro-pulmonary perforation is obvious. Other suggestive points are maintenance of a pneumothorax in spite of deflation, amphoric breathing over a pneumothorax cavity in some cases, and the lung fistula sound. Inversion of a patient may reveal by clinical signs a fistula previously sealed by fluid.
2. The injection into the pleural space of dyes and volatile substances may by their subsequent detection in the sputum reveal the presence of a fistula.
3. Pleural pressure studies such as the test of Bard and of Dumarest.
4. X ray of the chest in inspiration and expiration may suggest a fistula by the behaviour of the mediastinum and collapsed lung.
5. A fistula may be visualised by thoracoscopy.

In addition to these methods it is possible to detect a pleuro-pulmonary perforation by gas analysis, and the purpose of this paper is briefly to describe this method.

Since the original observations of Davy [1] in 1823, numerous records have been made of the composition of the gas in the pneumothorax cavity. So far this method has been used in the study of special cases only. It can however be used as a routine procedure, and the air in the pleural space can be examined with the same ease as a pleural effusion. A sample of gas is taken from the pneumothorax cavity into a sampling tube by displacement of mercury and its oxygen and carbon dioxide content determined.

APPARATUS AND TECHNIQUE

Any apparatus is suitable which is capable of analysing a sample of gas of about 10 c.cm. volume and in which the CO_2 and O_2 together are not more than about 25 per cent. Accuracy to two places of decimals is not necessary, since only large and definite variations of oxygen and carbon dioxide are clinically significant. Small and portable machines are liable to imperfections and leaks which invalidate the method, and it is easier and better to carry the sample to the machine than the machine to the patient. A good sampling tube is essential, and the model here illustrated was made so that a sample could be obtained at about atmospheric pressure and transferred to the gas analysis apparatus without any possibility of leakage.



It has a capacity of 25 to 30 c.cm. and obviates the necessity of a special tube for washing out the connexions. A sample is taken through A and B by lowering the levelling bulb. This contaminated sample is expelled through C, having closed tap 1 and turned tap 2 so as to connect the sample tube and C. Another sample is then taken. The outlet D is to enable the mercury from the apparatus to fill the tubing as far as tap 1 before the specimen is expelled for analysis.

Most phthisiologists now use atmospheric air in the pneumothorax cavity, but it is known that no matter which of the gases hitherto used is introduced into the pleural space, the resulting mixture has a fairly definite composition, provided that the gas has no irritant effect on the pleura. When air is introduced into the pleural cavity, CO_2 diffuses into it from the capillary blood more rapidly than oxygen passes from the pleura into the blood; this causes a temporary increase in the volume of the pneumothorax first noted by Dautrebande and Spehl.[2] However, in a matter of hours equilibrium is established. The actual composition of the pleural gas will be changed by variations in degree of collapse of the lung, by histological changes in the pleura, and by the presence of pleural effusion.

In order to provide a background on which these results can be judged, the gas content of the pneumothorax cavity has been examined in 150 cases, and from this series the following conclusions can be drawn:—

Whereas the atmospheric air contains about 21 per cent. oxygen and practically no CO_2 (0·03 per cent.)

---

* From the Sea View Hospital, New York City, and the Respiration Laboratory, Royal Victoria Hospital, Montreal.

the air of a dry pneumothorax cavity contains roughly between 1 and 5 per cent. of oxygen and between 6 and 8 per cent. of CO_2.

When inflammatory fluid or exudate is present the oxygen content is low and may be below 1 per cent., and the CO_2 is high and usually over 10 per cent.

In the present series of cases without fistula the oxygen content of 60 dry cases varied from 0·9 per cent. to 4·56 per cent., and the CO_2 content from 5·85 per cent. to 10 per cent.

In 90 cases with definite fluid present the oxygen content varied from 0·4 per cent. to 4·31 per cent., and the CO_2 from 9·84 per cent. to 14·7 per cent.

As long ago as 1876 C. A. Ewald showed that the air in open pneumothorax contained 16·75 per cent. oxygen, which fell to 2·6 per cent. when the fistula closed, but no detailed studies were made. In many cases the sum of the evidence may show very definitely that the fistula is open, but in others it may be difficult of proof.

ILLUSTRATIVE CASES

In ten cases analysis of the pleural gases was of value in demonstrating the presence and state of a pleuro-pulmonary perforation. The following are details of three of these cases:—

(1) A. B., male aged 50.

Had extensive bilateral pulmonary tuberculosis when first seen. Sputum was Gaffky 10 and fluid in the right chest contained tubercle bacilli. He was considered unfit for artificial pneumothorax, but he developed a spontaneous pneumothorax in the left side and was deflated many times.

Gas analysis showed oxygen 1·14 per cent. and CO_2 12·2 per cent., and four days later oxygen 2·5 per cent., CO_2 11·5 per cent. Three days later 2000 c.cm. of fluid were removed, and by shifting the patient samples of gas were obtained at intervals during the removal of the fluid. These showed—

O_2 ..	2·0 per cent.	CO_2 ..	11·3 per cent.
O_2 ..	2·12 ,,	CO_2 ..	13·18 ,,
O_2 ..	2·16 ,,	CO_2 ..	13·20 ,,

At this point the patient developed sudden dyspnœa and pain in the chest. Amphoric breathing and bubbling sounds were heard at the left base. Gas analysis showed oxygen 10·21 per cent., carbon dioxide 9·85 per cent., indicating that air had entered the pleural space from the lung.

At autopsy a pyopneumothorax with a bronchial fistula was found.

(2) C. D., male aged 26.

Had a spontaneous pneumothorax on the right side two weeks before admission. Gas analysis showed—

O_2 ..	3·8 per cent.	CO_2 ..	8·2 per cent.
O_2 ..	2·1 ,,	CO_2 ..	8·7 ,,
O_2 ..	1·2 ,,	CO_2 ..	11·3 ,,

When fluid developed analysis showed O_2 0·9 per cent., CO_2 12·6 per cent. Later he developed rise of temperature, dyspnœa, cyanosis. Gas analysis showed O_2 8·5 per cent., CO_2 11·7 per cent., indicating that a pleuro-pulmonary fistula had opened. The coughing up of gomenol in oil previously put into the pleural space confirmed this.

(3) E. F., male aged 18.

Had initial pneumothorax on the left side five months after the onset of illness. Five weeks later fluid developed which subsequently showed tubercle bacilli. Gomenol in oil was injected as a disinfection oleothorax and was coughed up. An X ray photograph showed the gomenol to have disappeared. Methylene-blue was also coughed up. Two gas analyses showed—

O_2 ..	8·52 per cent.	CO_2 ..	9·60 per cent.
O_2 ..	7·61 ,,	CO_2 ..	9·75 ,,

indicating a broncho-pleural fistula.

PERCENTAGE OF FAT IN HUMAN MILK

INFLUENCE OF THE METHOD OF EXTRACTION

By Margaret Frances Lowenfeld, M.R.C.S. Eng.
CO-DIRECTOR OF INSTITUTE OF CHILD PSYCHOLOGY

Sibyl Taite Widdows, B.Sc. Lond., F.I.C.
LECTURER IN CHEMISTRY AT THE LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN; AND

Hazel H. Chodak Gregory, M.D., M.R.C.P. Lond.
PHYSICIAN FOR CHILDREN'S DISEASES, ROYAL FREE HOSPITAL

Clinicians interested in infant feeding are continually brought in contact with the problem of fat absorption, and except for the generally accepted fact that the strippings of a breast or udder contain more fat than the milk of the earlier part of the feed, it has been usually assumed (see Truby King manual) that the percentage of fat in human milk remains roughly at an average of 3·5.

In a recent paper in the *Biochemical Journal*[1] the authors reported results obtained in an investigation of the fat percentage. Previous work[2] on the percentage composition of early milk had suggested that the method of extraction exerted considerable influence on the percentage of the fat although that of the other constituents was not affected. There has always been a considerable variation in the fat percentage of human milk recorded by different investigators, without any reasonable grounds for this variation being suggested. We may summarise the facts already put forward.

With regard to the factors which influence the percentage of fat in milk, these are method of extraction, period of lactation, individual variation, and the volume of the milk in the breast at the time of taking the sample; all of which were taken into account when considering the effect of the method of extraction.

In the normal action of the baby feeding two mechanical factors are concerned, pressure and suction. Direct pressure exerted by the gums of the baby upon the nipple and areola of the breast, and suction action exercised by tongue and cheek drawing on the openings at the end of the nipple. Digital expression and gentle suction from a breast pump, used without pressure on the breast, seem to give the nearest approach which can be made artificially to reproduction of these two factors of the normal process, and were the methods of extraction employed by us. As a result of systematic comparisons made by these two methods (details of which were given in the *Biochemical Journal*[1]) it was shown that pressure is the most important factor in producing a high percentage. The greater the pressure the steeper the rise in the fat percentage. Suction alone tended to lower the percentage.

It is a well-known fact that the percentage of fat in samples taken at the end of a feed is normally higher than that in the milk taken from the breast at the beginning of the feed. Yet it was possible, by using digital expression to extract the milk at the beginning of the feed, then allowing the baby to feed for three minutes and using the breast pump to extract the end milk, so as to show that not only was this difference annulled, but that the percentage of fat in the end specimen in some cases was actually lower than that in the one taken before the feed. After investigating the milk of 51 mothers and analysing 294 specimens, the conclusion we drew was the following: that in any given sample of milk, other factors being equal, the percentage of fat present will depend inversely on the *quantity of milk in the breast* at the time of taking the sample, and directly upon the degree of pressure exerted upon the areola and nipple in the process of extraction. The practical use to which the above facts have led has been in the treatment of certain clinical difficulties occurring in connexion with breast-fed infants.

It is generally agreed that of all the ingredients of milk, fat is the most difficult for the infant to digest. Czerny and Keller[3] state that only few children can tolerate high fat percentage in their feeds. The majority of infants who are fed for a long period on high fat milk mixtures become pale and ultimately more or less anæmic. These observers also state their experience that infants on high fat rations suffer from vomiting, and that the vomiting fails to respond to therapeutic measures, and only yields to an alteration in the diet. In Prof. Findlay's wards at the Royal Hospital for Sick Children, Glasgow, "fat dyspepsia" was recognised as a definite clinical entity. This diagnosis was made because the vomiting and failure to put on weight, for which the infants were admitted to hospital, were completely relieved by the substitution of skimmed milk mixtures for the whole milk which the infants had previously been taking.

Brennerman[4] states that: "The amount of fat in cow's milk has a decided effect on coagulation, but even more so on the emptying time of the stomach. Fat-free milk coagulates more quickly and completely than does whole milk, and forms a harder, whiter curd. The richer the milk in fat, the slower and less sharply defined is the separation into curds and whey, the yellower and smaller and softer the curd, but the harder to digest and the slower to leave the stomach." Because of this effect of fat in forming smaller and softer curds, Macy[5] erroneously attributes to Brennerman the statement that fat aids the digestion of protein. Some dried milk manufacturers have put a half-cream milk powder upon the market.

While high fat percentages undoubtedly interfere with digestion, it is important not to overlook the value of an adequate supply in the feeds of weak and undernourished babies. This has been specially emphasised by Koeppe,[6] who has observed improved growth and development in some weakly infants suffering from malnutrition, when they have been allowed to secure the last portion of the milk from the mammary gland. Our observations on the fat percentages obtained in milk samples by different methods of extraction show that the percentage of fat ingested even from the same breast by different infants will vary considerably, a baby who is a vigorous sucker being able to obtain a higher proportion of fat than the child who is a poor sucker. Macy and her collaborators state that Dr. Emmet C. Troxell, as a dermatologist, has observed that in some vigorous, hardy, breast-fed infants a certain type of eczema develops that clears up by shortening the nursing period and by allowing the infant to feed from both breasts, and thus preventing the baby from obtaining the strippings.

In the Infant Welfare Department of the Royal Free Hospital, in coöperation with Dr. Hazel Chodak Gregory, clinical observations were made along the lines suggested by the findings in our paper in the *Biochemical Journal*,[1] and, as a result of this work, it became possible to put the babies observed into two groups.

Type 1.—A small active baby showing dyspeptic symptoms such as vomiting and green stools. Careful inquiry and observation elicits the facts that the baby is a very vigorous sucker and that the mother's *milk yield is not plentiful*. This baby is getting a milk containing a very big percentage of fat, probably the highest fat percentage possible for this woman. As the quantity of fluid ingested is small, the total *fat will be proportionately large*. This condition, once recognised, we have found, can be rectified by an understanding of the situation and an alteration of conditions. The aim to be achieved is an increase of *total fluid resulting in a proportionate diminution of fat, combined with an absolute reduction in fat intake*. We have found that the first can be achieved by administering boiled water before and during the feed, the second by *ensuring that the infant does not get the strippings of the milk*. This can be secured by putting the baby to both breasts at each feed and not allowing the strippings to be taken from either. Manual stripping afterwards maintains the milk supply.

Type 2 is the exact antithesis of Type 1. Here the baby weighs above the average at birth, is contented and sleepy, and yet fails as time goes on to increase satisfactorily in weight, and this in spite of ingesting apparently adequate quantities of milk, a point which can be verified by test weighing. In many cases of this type studied, there was present an abundant supply of milk, but the musculature of the nipples was so lax that the milk tended to spurt from either breast before feeding. The baby is therefore in the position of taking dripped milk, which will be the lowest possible in fat for that mother (see *Biochem. Jour.*[1]).

As has been shown,[2] no effect is produced by the method of extraction upon the sugar content. Dripped milk will therefore contain a normally high sugar content. The second type of child is therefore obtaining a milk ample in quantity, normal in sugar, but deficient in fat, due to the fact that the baby does not suck, and the total feed therefore is practically that of dripped milk. We have found this condition to be corrected, first by lengthening the intervals of feeding, so as to allow the infant to get hungry and thus encourage *increased pressure and cause a rise in the percentage* of fat intake. Secondly by withdrawing some of the fore milk, and thus ensuring that what milk the infant can be induced to suck should contain a large *quantity of strippings*. By these procedures both conditions can be rectified without taking the baby off the breast.

It is possible that the facts that have been recorded *above may be of assistance to clinical officers* in coping with certain of the difficulties that arise in maintaining successful breast feeding.

HOSPITAL WAITING-LISTS.—It was stated at a recent meeting of the Swansea Hospital Board that the waiting-list has increased from 64 last year to 1149. The contributory scheme has now been joined by 955 firms and 85,000 employees belonging to them, and 25,000 unattached contributors.—The Fleming Memorial Hospital for Sick Children, Newcastle-on-Tyne, is stated to have a waiting-list of some hundreds. It has been swollen by a decrease in the number of beds "owing to the lack of space and modern sanitary arrangements."

CLINICAL AND LABORATORY NOTES

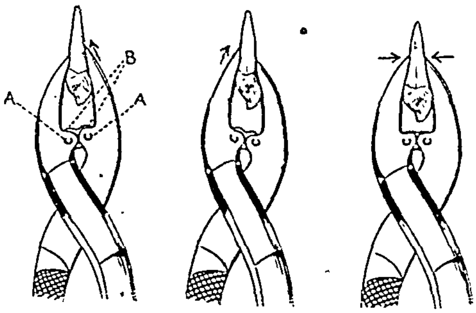
A NEW DUAL-ACTION PRINCIPLE IN TOOTH-EXTRACTION FORCEPS

By D. M. Shaw, L.D.S. R.C.S. Eng.

This note describes a new type of dental forceps and also reports opinion on the results of some first trials of the instrument in the extraction of over 300 teeth, as many as possible of which were selected as being likely to prove "stiff" or firmly planted units. Most of the extractions were done in private practice; some were at dental hospital clinics and in the dental department of a general hospital.

The Levatorceps, as it is called, differs from all ordinary forceps in that each blade or beak can, in a simple and effective manner, be independently thrust and advanced along the surface of the root for a short and safely controlled distance, the directional control at each forward thrust being made more complete by the maintained engagement of the opposing (and then stationary) beak. And thus, by the alternate and successive advance of each blade, the penetration of both blades to any desired depth is mechanically facilitated. The rootward penetration is in this way effected with only about half the manual thrusting effort required for that simultaneous advance of both beaks to which ordinary forceps are restricted. During the alternating advance of the thrusting beak through a short (2 to 4 mm.) and nearly flat arc, the fit and alignment of the other—the opposing and then less active—beak does not tend to be wrongly disturbed; with ordinary forceps the latter kind of faux pas is the not very uncommon result of the attempt to secure the wished-for advantage—of some degree of alternating single-beak penetration—by the makeshift of a rocking or swinging movement of the whole forceps. And further, the reasonable expectation that the gradual single-blade penetration might involve rather less bruising or crushing of the investing tissues appears to be supported by close observation of the levatorceps in action, as well as of the post-extraction condition.

FIGS. 1 2 3



4

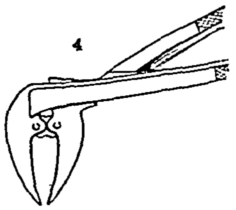


FIG. 1 shows the new principle of pivoting the main members solely on the twin axes A, A, which axes are situated at each end of a short link or shackle bar B, the latter having a restrained range of movement in the same plane as that of the opening and closing movements of the instrument. To save space, Fig. 1 also indicates the advance of one blade along the root surface.

FIG. 2 shows the advance, in succession, of the opposite blade.

FIG. 3 shows the "penetration" arrived at after a few alternating (and relatively moderate) thrusts in succession.

FIG. 4 shows a "hawk's-bill" forceps for lower teeth.

Although the levatorceps may fairly be said to combine in one instrument, and to a proved serviceable extent, the distinct and hitherto immiscible utilities of the elevator and the forceps, no absurd suggestion is here implied that the new instrument could take over or perform any of those operations in which the unique and invaluable services of the elevator proper are specially called for. In addition to the above-noted primary feature of the levatorceps, the more forward placing of each axis or fulcrum (*in front* of the usual and necessary "crossing" of the main members) provides, as the accompanying illustrations make sufficiently evident, a much greater leverage (mechanical advantage) and better non-slipping grasp of the root; and again with marked economy of manual gripping effort. In effect, and in surprising degree, there was experienced a welcome reduction in that muscular strain and fatigue from sustained gripping effort which sometimes, in stubborn extractions, compels the prudent operator to desist and take one or more rests. In the levatorceps, as in many types of ordinary forceps, the diagonal "crossing" is boxed in, thus affording an added security against undesired looseness in the more forward and real axes of movement.

The impression given by the 300 extractions with the levatorceps was that the teeth were dislocated and removed with decidedly increased ease, as compared with like extractions with ordinary forceps. The very firmly planted teeth, in particular, were extracted with an expedition and a minimum of strain that proved very satisfactory to patient and operator. In a few chance instances, in each of which a very "stiff" tooth did not even begin to dislocate during patient attempts with ordinary forceps, a change-over to the levatorceps quickly resulted in a successful whole-tooth extraction. The new instrument proved serviceable also in extractions of displaced and incompletely erupted teeth removed for the regulation of crowded dentitions.

Any desired shape or size of beak or of handles may be incorporated in the levatorceps. Moreover, the alternating single-blade method of penetration is quite optional—that is, there is nothing to hinder the operator from using it, at will and at any operative stage, by the simultaneous advance of both beaks, just as with ordinary forceps. This latter choice of a variable technique has indeed in some cases been advantageously applied during multiple extractions, wherein some of the teeth were stiff and some were easy propositions.

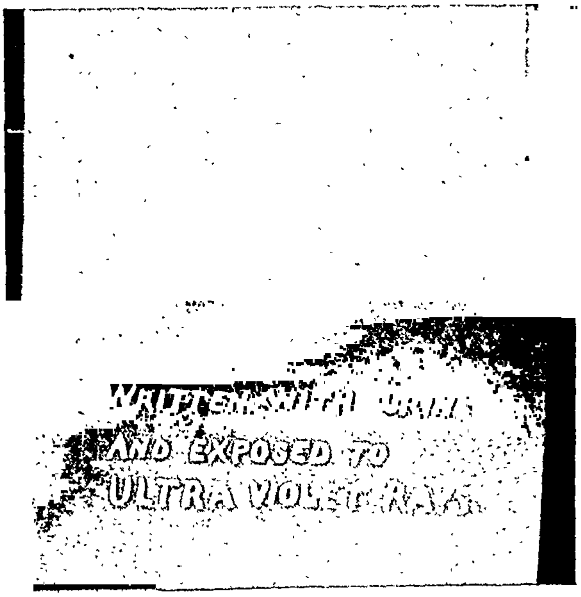
One of the arguments stressed by proponents of the open or "surgical" removal of teeth pointed earnestly to the lamentably large proportion of broken teeth and roots, unremoved root remnants and sequelæ associated with extraction and attempted extraction by forceps. They urged that that long trail of trouble would be reduced to about vanishing point if and when the advised surgical method came to be widely adopted. However that may or may not be, no one can safely assert that the limits of perfection or usefulness in forceps design have already been attained. The number of teeth relegated to treatment by forceps in this country alone amounts to several millions in each year. And so the advent of a new type of instrument by which adequate penetration along the socket is made surer and easier, and a stronger non-slipping grasp obtained with relatively less effort, is perhaps of sufficient general interest to merit further attention and trial.

SECRET COMMUNICATIONS MADE VISIBLE

By F. W. MARTIN, M.D. Glasg.
ASSISTANT, FORENSIC MEDICINE DEPARTMENT, UNIVERSITY OF GLASGOW; AND

KONRAD BEÖTHY, M.D. Pécs
LECTURER, MEDICO-LEGAL INSTITUTE, PÉCS UNIVERSITY, HUNGARY; ROCKEFELLER RESEARCH FELLOW AT GLASGOW UNIVERSITY

ULTRA-VIOLET radiation has come to be recognised as a force both valuable and versatile in its application. Criminologists have found filtered ultra-violet light a valued assistant in many spheres of their work. Existing literature provides ample evidence of the many possible applications of the filtered ultra-violet ray. Investigations with these rays can be carried out expeditiously, and are simple in execution. Moreover, the test as applied by the analytic quartz lamp has the valuable advantage that the object under examination is in no way damaged, marked, or altered. As has been pointed out by Rubner,[1] and also by Goodman,[2] correspondence to and from prisoners can be examined in a few seconds by exposure to filtered ultra-violet light, since the substances commonly used by prisoners for secret writing—e.g., urine, saliva, milk, all show fluorescence on such exposure.



Two photographs of a sheet of paper on which is a sentence written with urine. Above, by ordinary light. Below, by filtered ultra-violet light.

No evidence of the exposure is left on the communication and this method of rendering the invisible visible is far in advance of the usual method of heating. Where heat is used the writing turns black or brown. As a result the communication cannot be sent to its destination, because suspicion would be at once aroused. Under filtered ultra-violet light, however, such writing is read without altering the letter or communication in any way, since the rays leave no trace of any kind to warn the recipient, and thereby put him on his guard.

Such photographs form a permanent record of the invisible rendered visible, and may be produced in a court of law and submitted with striking effect to a jury.

A NOTE ON THE VALUE OF THE DICK TEST FOR INSTITUTIONAL PURPOSES

By R. M. BATES, F.R.C.S. Eng.
RESIDENT MEDICAL OFFICER, STOKE PARK COLONY, BRISTOL

THE first evidence of an outbreak of scarlet fever in Stoke Park Colony (for mental defectives) occurred when two children simultaneously developed the disease. They were isolated at once, but both were school-children and it was found that the direct and indirect contacts among the patients numbered 389. It was decided that an attempt should be made to check the epidemic and to "Dick-test" all the contacts. The youngest children were tested first.

The method used was that generally employed—namely, the intradermic injection into the left forearm of 0·2 c.cm. of a dilution of the filtrate obtained from a broth culture of the *Streptococcus scarlatinæ*. Into the right forearm a similar injection was made of 0·2 c.cm. of the same toxin, boiled for two hours. The toxin and control were both obtained already diluted. Injections were given into both forearms simultaneously and great care was taken to ensure that the weal raised was of the same size on each forearm. After injection the patients were examined in twenty-four hours and again in forty-eight hours. It was occasionally necessary to make a third examination, especially in those cases in whom there was a definite reaction on both forearms. It was found that when the reaction on the left side was larger than that on the right a definite positive reaction subsequently developed.

All patients giving a positive reaction received 4 c.cm. of antiscarlatinal serum intramuscularly—the outer side of the thigh being used in all cases.

On the first day 58 patients were tested, of whom 23 gave positive reactions in twenty-four hours. Of these 23, 2 patients had developed scarlet fever at the time of examination. All were given serum and the cases of scarlet fever were isolated. Testing was continued each day and a list was kept of the name and age of each patient. Of the 389 patients tested 69 were Dick-positive and each received 4 c.cm. of antiscarlatinal serum. No fresh cases of scarlet fever occurred. Thirty-seven members of the staff were Dick-tested at the same time, of whom 10 gave a positive reaction. The same intramuscular injection of 4 c.cm. of antiscarlatinal serum was given in these cases. Of the 79 cases receiving "passive immunisation" only one, a member of the medical staff developed serum sickness.

Age-groups.	*Total patients.*	*Positive reactors.*	*Per cent. positive.*
5–10	49	21	42·8
10–15	79	17	21·5
15–20	96	14	14·6
20–25	49	5	10·2
25–30	42	1	2·4
30–35	42	4	9·5
35–40	22	6	27·2
40–45	10	1	10·0

The patients tested (exclusive of staff) were arranged in five-year groups as in the accompanying Table, and the percentage of positive reactors in each group calculated. The percentage of Dick-positive patients in each age-group shows a very regular fall down to the age of 30, which is significant of a regularly increasing immunity to the streptococcus. The apparent rise after the age of 30 is more difficult to interpret. Of the 1700 patients at present alive in this institution a recent analysis of their age-incidence shows that only 6 per cent. have reached the age of 35 or over. In the last 400 consecutive deaths in this institution 96 per cent. died before reaching the age of 30. The rise in the Dick-positive percentages after the age of 30 may therefore point towards a decreasing immunity to the streptococcus and possibly to other organisms.

It must be pointed out, however, that comparing the percentages of Dick-positive patients in the 20–30 and over-30-year age-groups a result is obtained which could be produced by random sampling once in 12 times, and the apparent rise may therefore be due to pure chance.

I am indebted to the director of medical services, Prof. R. J. A. Berry, for permission to publish this paper. The incidental expenses were borne by the Rosa Nelson Burden research fund.

REVIEWS AND NOTICES OF BOOKS

The Anæmias

By Janet Vaughan, M.D. London: Humphrey Milford, Oxford University Press. 1934. Pp. 248. 12*s.* 6*d.*

This monograph is a review of present knowledge of hæmatology, and more especially of the advances that have been made during the last five or six years. It is limited to disturbances of the red cells and their precursors, leukæmia and the hæmorrhagic diseases being mentioned only in so far as they affect the erythron. Dr. Vaughan has succeeded admirably in giving a clear picture of modern conceptions of anæmia, and the book, moreover, contains the outcome of much previously unpublished research in which Dr. Vaughan has been associated with Prof. H. M. Turnbull, whose descriptions of normal erythropoiesis and the pathological anatomy of the anæmias are an important contribution.

One of the most useful tools in hæmatological research has been the exact measurement of the size and the hæmoglobin content of the erythrocytes, and it is therefore fitting that the book should open with a summary of these data. The leading motive of the book is the paramount importance of disturbance in the maturation of the red cells in the causation of anæmia. Dr. Vaughan holds that many of the anæmias which have been attributed to hæmolysis are really the result of disturbances in the metabolism or nutrition of the red cells, and it certainly appears doubtful whether we are justified in describing an anæmia as hæmolytic unless free hæmoglobin is detected in the plasma or the urine. A notable section of the book, which is chiefly founded on personal research with Prof. Turnbull, deals with the anæmia, characterised by the presence in the peripheral blood of a few immature white cells of the myeloid series and immature red cells, which appears in certain cases of carcinomatosis with deposits in the bones, and more seldom in other diseases of the bones. For this condition the title leuco-erythroblastic anæmia is proposed and seems more suitable than the previous equivocal nomenclature. In spite of the reticulocytosis, there is no definite evidence of excessive destruction of the red cells, and it appears that the carcinoma cells in some way disturb the maturation of the red cells and render the bone-marrow dysplastic. Rather similar disturbances of the maturation of the red cells occur in the anæmia due to internal radiation with radio-active substances, of which Dr. Vaughan gives a careful description. This anæmia was first observed by Martland in women who had been employed in painting luminous dials and had absorbed the radio-active material from their brushes. While Dr. Vaughan's monograph was in the press, Hamilton Fairley has reported the inhibition of erythropoiesis produced by malaria, amœbiasis, and other tropical infections, and the reticulocyte crises which follow the destruction of the parasite by the appropriate chemotherapy. It is probable that Dr. Vaughan's chapter on toxic dyshæmopoietic anæmias will need expansion in the future, as more is learnt of the agencies which inhibit erythropoiesis and the mechanism through which they act.

Idiopathic hypochromic anæmia and pernicious anæmia are remaining more and more in the hands of the general practitioner, now that their treatment has been simplified and systematised. The attention of the research worker, the pathologist, and the consultant physician is thus transferred to the obscure cases which have failed to respond to ordinary treatment and are obviously of a different type. It is for such workers that this monograph will prove invaluable. It contains accounts of all the rarer forms of anæmia and the special investigations that may help in diagnosis. It should also provide a stimulus to research. There is still much to be learnt and Dr. Vaughan has not failed to point out the tasks that await the hæmatologist.

Biochemistry of Nitrogen Conservation

An Introduction to the Biochemistry of Nitrogen Conservation. By Gilbert J. Fowler, D.Sc., F.I.C., Professor (retd.) of Biochemistry in the Indian Institute of Science, Bangalore. London: Edward Arnold and Co. 1934. Pp. 280. 12*s.* 6*d.*

Let no man allow a dread of biochemistry, instinctive or acquired, to prevent him reading this book. The problem of the satisfactory utilisation of nitrogenous waste material is that of encouraging the right organisms in the right time and place. A kindly Nature has placed them for man's assistance in both soil and sewage. His acceptance of her gift involves public health, economics, and sociology, in addition to microbiology and biochemistry. All these aspects are discussed in Prof. Fowler's book; and if biochemistry is prominent, it is because the prevention of a smell developing and of nitrogen being utterly wasted depends largely on the application of that science. The author is kind to his readers. For those ignorant of microbiology, a short description of the commoner types of organisms and of bacteriological technique is given. For those who know but little biochemistry a brief summary of the chemistry of proteins and carbohydrates is provided.

The importance of two problems is emphasised. The satisfactory disposal of sewage needs no recommendation; but the appalling waste of nitrogen is perhaps not generally appreciated. The total world consumption of "manufactured nitrogen" for agriculture is 1,300,000 tons per annum. The nitrogen excreted by the world population in urine and fæces is 4,000,000 tons per annum, or over three times as much as is required for agriculture. It is interesting to learn that China has been leading the world in nitrogen conservation. Her farmers are masters in the art of making compost from refuse, and are accustomed to use the nightsoil of her cities for the manuring of their crops. Nowadays, however, all over the world "disposal" is beginning to give way to "conservation." That it is not general in Britain is due to the rich nature of the soil, which has no great need of fertilisers. It is perhaps in India that the demand for conservation is most urgent. On the problems of India the author writes with the authority of experience. The insanitary habits and the use of dried fæces as fuel are particularly unfortunate in a land whose demand for organic manure is practically unlimited.

The book describes the various methods of treatment of sewage and sullage. From the older processes of "dilution" by discharge into lake or sea, of treatment in septic tanks and by aerobic clarification, of final purification in contact beds and trickling filters, we come finally to the activated sludge process with the development of which the author had much to do. By its use sewage is converted into an inoffensive brown humus of great agricultural value and a clear odourless solution of nitrates.

The nitrogen undergoes many chemical reactions in passing from urea and protein to the form of nitrate in which it is assimilated by plants. The description of these reactions and the part played by the various organisms of nitrification, de-nitrification, and nitrogen-fixation is by no means the least interesting part of the book.

Evolution of the Vertebral Column

A Contribution to the Study of Vertebrate Phylogeny. By H. F. Gadow, M.A., Ph.D., F.R.S., late Strickland Curator and Reader in Vertebrate Morphology in the University of Cambridge. Edited by J. F. Gaskell and H. L. H. H. Green. London: Cambridge University Press. 1933. Pp. 356. 25s.

There is something of a melancholy interest in the appearance of this posthumous book. Only a few years ago its author was deservedly famous in the world of morphology, and already he is little more than a name to the student of the subject. The editors have done well in bringing out these notes which, although somewhat fragmentary, were evidently intended for publication in book form. Dr. Gadow's outlook on morphology was derived directly from his great master, Gegenbaur. It is bracing to come across such formal monuments of encyclopædic learning in these days when we have swung away after other (but not therefore false) gods, and have neglected to some extent the hard road which morphologists were wont to tread. We have to return to it from time to time, for only thus can we discover the historical element which, to an increasing degree, is being recognised as essential in the study of the organism. Thus this book will take its place as a record of information and work of reference in the future. It is coloured, of course, by the views of its author, which are not always generally accepted. As an instance we may notice, because of its human interest, that Dr. Gadow seems to have held firmly throughout to his conception of the evolution of the mammalian centrum, while probably most morphologists to-day are inclined to support Cope's reading, which gives the main value to the interdorsal. Dr. Gadow's original view concerning the value of the interventral has always seemed to us to have much in its favour. He does not appear to have been acquainted with Barge's work on occipito-atloid development: it is possible, though not by any means probable, that it might have modified some of his opinions.

This monograph deserves study. The second part, which deals with systemic morphology, presents a mass of observations which would without doubt have been welded into a coherent whole by the author, if he had lived. As they stand they are, at the least, records of a multitude of facts, and in many places and ways are suggestive of the lines along which the mind of their compiler was working. Dr. Gadow had always been interested in vertebral evolution in association with vertebrate evolution, and, as the editors say, the book is a "culmination of investigations and reflections of the greater part of an active life devoted to the morphological problems of the vertebrate phylum." Such a book has a definite place in morphological literature.

The Behaviour of Animals

By E. S. Russell, D.Sc., London: Arnold and Co. 1934. Pp. 184. With 32 illustrations. 10s. 6d.

Those who are distracted with trying to understand why people do what they do may well turn for relief to Dr. Russell's account of the behaviour of animals. He treats the subject in an objective way, as a description of what may be observed, and eschews both the method which seeks to dissect behaviour into a series of tropisms and that which explains the facts in terms of human emotions. The actions of animals must, he says, be looked upon as wholes which, like their bodies, are something more than the sum of the parts, nor can they be understood without reference to the end which is reached any more than development is intelligible without considering the mature product. About instinctive and intelligent behaviour he takes the commonsense view that no sharp separation is possible; purely instinctive action is probably as rare as purely intelligent and the two grade into one another. And he urges that, for the present at any rate, simple observation and experiment should replace attempts at explanations partly in physiological and partly in psychological terms. The book may irritate those who have learned from Dr. Russell's previous books to dislike his organismal outlook, but it is delightfully written, clear, and readable, and it should do much to encourage the accurate natural history studies which he would like to promote.

Die Entzündung des Magens

By Dr. med. Norbert Henning, Privatdozent in the University of Leipzig, Oberarzt in the Medical Clinic. Leipzig: Johann Ambrosius Barth. 1934. Pp. 235. RM.23.40.

The German stomach has been extensively investigated in recent years by two new methods. The radiologist introduces a small quantity of a thin barium emulsion, compresses the organ with a pad applied over the abdominal wall, and screens or photographs it; the barium lodges in the sulci of the mucous membrane and outlines the configuration of the rugæ. The physician passes a gastroscope, usually the new safe flexible instrument, distends the stomach with air, and finds himself able to look at the greater part of its inner surface. Nowhere in Germany have these two methods been practised more thoroughly or more extensively than in the huge Leipzig clinic of Prof. Morawitz.

Dr. Henning has handled the whole gastric material of that clinic for the past six years, and his descriptions and opinions are based with convincing directness on his own experience. Chronic gastritis for him is a morphological change in the gastric mucosa. Radiologically the rugæ appear larger, broader, more irregular than normal, less easily altered in shape by palpation and distension; in atrophic gastritis they are abnormally tenuous. Gastroscopically, swollen stiff distorted rugæ can be easily recognised, the normal smoothness of the epithelial surface may be replaced by a knobby or granular irregularity, multiple superficial erosions and hæmorrhages are often seen; in the atrophic cases the large vessels of the submucosa become visible through the shrunken thinned mucosa. These changes are fully described and illustrated in the book. An extensive correlation of them with microscopic appearances has not been possible, since few cases are treated surgically. A correlation has been attempted, however, with the clinical histories of the patients, and with the chemical alterations in gastric secretion. In this, the author's enthusiasm does not betray his judgment. The facts are that some patients with chronically inflamed stomachs, but without ulcers, give ulcer-like histories; others have had less characteristic dyspepsias, usually only for a year or two, and many have had no gastric symptoms at all.

The chapters on ætiology and treatment are good, but they record no striking advance. There are short accounts of the gastric changes associated with ulcer, carcinoma, gastro-enterostomy, biliary tract affections, and pulmonary tuberculosis. The illustrations include many good photographs taken with the author's gastroscopic camera. The book is a well-written, well-balanced account of the author's experience, set against the background of current German teaching.

The Dinosaurs

By W. E. SWINTON, Ph.D. London: Murby and Co. 1934. Pp. 233. With 25 plates and 20 figures. 15s.

Dr. Swinton has produced a readable and interesting account of that strange group of reptiles which occurred all over the world in triassic, jurassic, and cretaceous times and then disappeared for ever, just as mammals were beginning. Besides the desirable anatomical details of the different groups, there are supplied a number of pictures of reconstructed living specimens and throughout their structure is discussed as an indicator of their habits and modes of life. Many of them were small and possibly graceful beasts; better known are the "fearfully great" (as Owen put it) monsters weighing four or five times as much as a big elephant, which impress visitors to our museums. The most interesting chapter for the general reader is perhaps the one in which Dr. Swinton discusses the cause of their disappearance. Was it intrinsic or extrinsic? Did they grow too large and complicated? Were they too stupid (for in some of them the lumbar enlargement is bigger than the brain)? Did some animal arise that ate their eggs (actually found in Mongolia)? Or was there some development of destructive parasites? The author comes to no conclusion, but inclines to think that the scales were finally weighted against them by widespread geological and climatic changes.

MEDICAL SOCIETIES

SOCIETY OF MEDICAL OFFICERS OF HEALTH

AT a meeting of this society held at Upper Montagu-street, London, on April 27th, under the presidency of Dr. G. STANLEY BANKS, a discussion took place on the

Relationship of Measles and Whooping-cough to Chronic Inflammatory Conditions of the Chest

Dr. C. D. AGASSIZ dealt mainly with cases seen in a children's hospital. He said that non-tuberculous fibrosis of the lung in children was first demonstrated by Andrew Clark, W. J. Hadley, and Arnold Chaplin in 1896, and little further work had been done on the subject until comparatively recently. The subjects of this fibrosis might appear robust, but usually had some cyanosis of lips, cheeks, and ears, especially after exercise. Some had a dusky pigmentation, and others had a thickening of the nose. Anæmic children might not show cyanosis until the anæmia had been treated. Dr. Agassiz had found cyanosis present in half his cases, though in only one-third was the circulation affected. Blood oxygenation was definitely lowered. Clubbing of finger ends varied in degree. Cough was a main symptom in 60 per cent. of the cases; sometimes this was paroxysmal and recurrent, but was usually described as bronchitis. Expectoration was infrequent, occurring only in about 1 in 5 cases; the sputum was scanty and glairy and no tubercle bacilli were found in it, but occasionally streptococci and pneumococci. Hæmoptysis was comparatively rare, though sometimes half an ounce of blood might be coughed up. Dyspnœa was present in over 40 per cent. of the cases, exercise bringing on a degree of dyspnœa out of proportion to the effort. Poor lung expansion sometimes occurred bilaterally, but more often in one lung, the percussion note being impaired especially at the base. There might even be cavernous breathing, and sometimes when the child's mouth was open crackling râles could be heard. These children seemed particularly liable to what appeared to be broncho-pneumonia; there might be signs of lobar pneumonia, or febrile conditions with slight dyspnœa. At this period X rays showed certain characteristic appearances; the heart might be pulled over towards the affected side. In many cases there was a history of several bouts of so-called bronchitis or broncho-pneumonia, often of a persistent winter cough, and of an onset following measles, whooping-cough, or pneumonia. It was probable that the primary lung condition started with the measles or whooping-cough. About 44 per cent. of his cases gave a prior history of measles, 33 per cent. of whooping-cough, 31 per cent. of pneumonia. An important differentiating test was the Mantoux test, especially if negative. If it was positive, other factors must be depended on for distinction from tuberculosis. Non-tuberculous fibrosis could hardly be distinguished from pneumonia, if at the time of the examination the child had pyrexia associated with some consolidation. Where there was no pyrexia and no evident respiratory distress, the diagnosis from pleurisy or pleural effusion should not be difficult. It had so often been taught that measles and whooping-cough were precursors of tuberculosis in children that research should be undertaken. Some died in a pneumonic attack but for the most part the immediate prognosis was good; the remote prognosis was still unknown. A few patients developed bronchiectasis, but most recovered, at least as shown by signs and symptoms, and with the growth of the child any unhealthy area of lung bore a smaller proportion to the whole. Of 42 cases which he had followed up for three to six years, only one died of pulmonary tuberculosis, one developed bronchiectasis, the remainder were fit for work or for school. In the few who developed tuberculosis this was of the slowly advancing fibrotic type. There was need for mass research work on the subject, which could only be thoroughly carried out at the large fever hospitals.

Dr. **George Jessel** spoke from his experience of dispensary practice. Practitioners referred many cases of intermittent or chronic cough to tuberculosis officers. Often the illness had been preceded by measles or whooping-cough; in other cases attacks of those diseases might have occurred in forms too mild for recognition, the chest sequelæ being quite as serious. In 1933, in Dr. Jessel's area, 282 children were examined on account of chest symptoms; 83 of them gave a history of measles or whooping-cough. Of these 83, 5 were found to have pulmonary tuberculosis and 15 non-pulmonary tuberculosis. Of the 199 children who gave no history of measles or whooping-cough 4 had pulmonary tuberculosis, 37 non-pulmonary tuberculosis. Of the total number of 282 children 221 were non-tuberculous; 63 of these gave a history of measles or whooping-cough. Dr. Jessel's conclusions were that the children who had had measles or whooping-cough showed a slightly increased incidence of tuberculosis over those who gave no such history, and that this increase was in the pulmonary form. In earlier years radiologists interpreted as evidences of tuberculosis shadows which now were known to bear a different meaning; for example, heavy shadows at the root of the lung were not necessarily caused by active tuberculosis.

Dr. **J. E. McCartney** dealt with the pathological side. The serious inflammatory condition in the chest was the lobular or broncho-pneumonic condition; it was an extension of capillary bronchitis, and was most severe when involving the terminal bronchioles, as it was accompanied by an interstitial change. This peri-bronchitis was characterised by severe congestion, an outpouring of fibrin, and, later, an extension of the condition into the alveoli. Often as a result of this there was an occlusion of bronchi, followed by collapse and atelectasis. The consequent dullness was often thought to be due to consolidation. The interstitial pneumonia seen in measles presented a different picture, as in it there was practically no exudate; the capillaries tended to be dilated, the alveolar walls were tortuous, the alveolar tissue thickened, the fibroblasts were increased, and the lumen was occluded by an increase of interstitial tissue. Bronchiectasis was caused by three different factors—mechanical, infective, and fibrotic. The mechanical factor operated by partially blocking a bronchus, and expiration needed a special effort. When to the blocked condition infection was added inflammation supervened, with a weakening of the musculature and of the elastic tissue, so that the fibres were torn apart and became œdematous, and the cartilaginous plates were separated. Pfeiffer's bacillus was frequently answerable for this. The fibrotic factor was due to a contraction of the connective tissue, extending from the terminal to the larger bronchioles and to the bronchi. The primary damage done to the lung in measles and broncho-pneumonia was interstitial inflammation, extending upwards from the smaller to the larger bronchi; these became occluded, collapsed, and were replaced by fibrous tissue, and the contraction of the latter gave a train of sequelæ. Much could and should be done in the way of prophylaxis against measles. When the next epidemic occurs supplies of adult human serum should be obtained, attenuated, and used for measles contacts, the public meantime being educated to realise its advantages.

Dr. **J. S. Westwater** said that unfortunately the physician in fever hospitals did not see the end-results of his cases. In the last measles epidemic the results he had observed conformed to those set out by Dr. Jessel, and showed that measles did not deserve the bad name it had acquired. He had traced a number of cases for two to four months after they left hospital. He used the Mantoux test as a means of differentiation from tubercle. Respiratory sequelæ tended to occur in the younger children and in those of any age who had had pulmonary complication; also in those who, before measles, had had some respiratory illness. This seemed to him to suggest that even if measles was attenuated, chronic pulmonary infection would not be eradicated. One of the prime factors in these troubles, he considered, was vitamin deficiency. He had not found that whooping-cough usually jeopardised the child's future.

Dr. **J. N. Dobbie** stressed the lack of resistance in the subjects of these children's complaints, and said some degree of rickets could often be found, though admittedly gross rickets was now much rarer than formerly. Some 70 per cent. of the children aged 5 in the London schools showed minor signs of rickets; and the earliest chance of the onset of the respiratory conditions under discussion was at the age when rickets was commonest and most serious. Prophylaxis against these complaints lay largely with maternity and child welfare centres.

Dr. **V. Freeman** emphasised the constitutional disturbances to the child afflicted with these respiratory diseases. Repeated attacks must lead to interference with the general growth; he had satisfied himself of this by an inquiry into the height-weight ratio at different ages and after different diseases.

The **President** said he had long felt that chronic chest disease in children was not occupying its due place in administrative and public health schemes; also that those who were dealing with such acute conditions as measles and whooping-cough did not quite properly correlate them with the sequelæ seen later. Of 100 children whose cases he had inquired into, 66 could be diagnosed as having chronic pulmonary catarrh or dry bronchiectasis; 60 gave a definite history of measles or whooping-cough, or both, and 6 had had pneumonia. Forty-two of them were negative to tuberculin tests, also to the Mantoux and von Pirquet tests. He agreed with what had been said about malnutrition in these children. In one industrial area he formed the conclusion that about 80 per cent. of all the children examined had some signs of rickets, possibly a general avitaminosis, of which rickets was only one manifestation.

Dr. **Agassiz**, in a brief reply, said a child with a rickety chest and a history of bronchitis probably had fibrosis, not tuberculosis. To attribute these chest conditions to vitamin deficiency was, he thought, carrying the cause too far back; but the connexion with measles and whooping-cough was very definite. The great need at fever hospitals was frequent X ray examinations and a follow-up of the cases.

Dr. **Jessel**, in reply, said that in the provinces very few of these children came into hospitals, a fact which accounted for the small proportion of fibrotic cases found in them.

EUGENICS IN PRACTICE

A Series of Essays suggested by the Report of the Brock Committee

I.—MENTAL DEFECT IN THE COMMUNITY: IS IT INCREASING?

In considering any steps which should be taken to control mental deficiency in the community, it is obviously of the first importance to know the extent of the problem. The Royal Commission, appointed in 1904 to consider, among other things, the existing methods of dealing with the mentally defective, found at the outset of their inquiry that there were no statistics available concerning the incidence of defect in the community. They therefore caused surveys to be made in different localities and by this means they estimated the incidence to be 4·6 per 1000 in the general population. In 1924 the Wood Committee, appointed jointly by the Board of Education and the Board of Control, met to consider certain administrative problems. This time a much more extensive survey was undertaken and the incidence of mental deficiency was estimated at 8·6 per 1000. The relative proportions of the different grades were found to be approximately 5 idiots, 20 imbeciles, and 75 feeble-minded to every 100 aments. In both these surveys the incidence in rural districts was found to be significantly higher than the incidence in towns. Superficially, it appears that the mentally defective had doubled their numbers in the course of 20 years. This conclusion is, however, held to be invalid by many authorities. In both these surveys the total number of defectives was probably under-estimated but, owing to greatly improved facilities for ascertainment, the alter survey was the more accurate.

The report (Cmd. 4485) of the Departmental Committee on Sterilisation, conveniently known as the Brock Committee, refers to the question of the extent of the problem in the following terms: "On this point the Wood Committee found it difficult to come to any definite conclusion, and we share their difficulty." The report goes on to state that the impression created by the statistics put before the Brock Committee is that the incidence of mental defect is increasing, though not rapidly. The increase may be due partly to better ascertainment and partly to improvements in the public health services calculated to keep alive defectives who would otherwise have died at a younger age. At the same time it is pointed out that there is no ground for the alarmist views expressed in some quarters that there is wholesale racial deterioration.

EXTENT OF DEFECT IS A MATTER OF DEFINITION

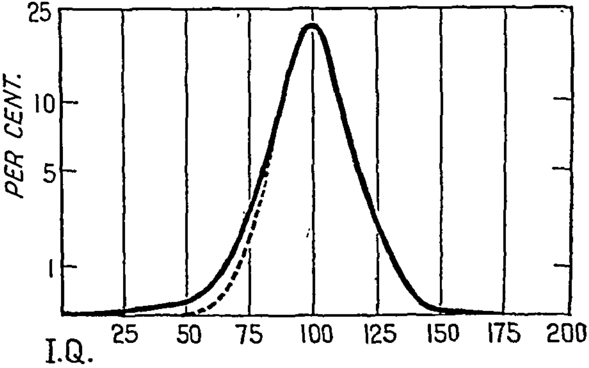
The definition of defect in the Mental Deficiency Acts is not based on mental tests, and authorities differ in their interpretation of the criteria by which it is judged. Though valuable to the administrator, the knowledge of the incidence of defect, as defined by the law, cannot be of much use in considering the problem genetically. As the Brock report states:

> "The definition in the Mental Deficiency Acts is based upon social adaptability, and the definition in the Education Acts upon educability. In other words, both statutory definitions rest upon the end result of the mental condition . . . . and not upon the clinical characteristics."

In other countries different definitions are used, but they are also subject to ambiguity. But, as Prof. R. A. Fisher points out, the educational criterion of deficiency is of greater significance than is the more sociological criterion of the Mental Deficiency Acts.

Thus the general distribution of ability in mental and scholastic tests forms a better basis for the genetic study of mental deficiency than the results of the surveys undertaken by the Royal Commission or the Wood Committee. Such investigations as that carried out by Burt (1921) on the London school population and the recent inquiry made by the Scottish Council for Research in Education (1933)[1] furnish us with suggestive material from this aspect. Unfortunately these surveys suffer from the disadvantage that many children at the upper or lower ends of the scale escaped observation. We can, however, infer from them that the distribution of intelligence, as judged by standardised tests, forms a continuous curve (shown in the diagram) from the lowest idiot to the cleverest scholarship child. The curve approximates, though not very closely, to a normal frequency distribution. There is some irregularity in the lower part of the scale and poor mental endowment appears to be more prevalent than would be expected if ability were distributed symmetrically round a norm. Practically no idiots and few imbeciles can be said to come within the normal range, though probably many of the feeble-minded belong to it. In practice the line of demarcation between normal and abnormal intelligence must, however, be drawn arbitrarily and the incidence of mental deficiency varies according to where this line is drawn. The position of this line is partly determined by administrative considerations. In London, where the borderline is taken to be between the intelligence quotients[2] (or mental ratios) of 66 and 75, provision in the special schools is made for about 1·5 per cent. of the school population. Similar figures hold for many other towns. On the basis of statistics of normal

Diagram showing distribution of intelligence among school-children



The figures at the foot of the diagram represent intelligence quotients (I.Q.): the upright scale denotes the proportion of individuals, per cent., who are distributed at the various grades of intelligence. The upright scale is logarithmic, so that the apex of the curve is very much reduced in height. The dark outline indicates the range of intelligence in the general community: it is not quite a normal probability distribution curve, since it is slightly skew towards the left. The dotted line indicates the limits of the distribution of intelligence found among ordinary school-children. The small segment of the total population to the left of the dotted line consists of the special school population, together with children whose mental grade is too low even for the special schools. The diagram shows (*a*) that there is considerable overlapping of I.Q. between the two groups to the left and right of the dotted line; and (*b*) that the proportion of children judged to be mentally defective depends upon where the dotted line is drawn. The diagram is based mainly on figures given by Cyril Burt in "Mental and Scholastic Tests," London, 1927, pp. 161–162.

---

[1] The Intelligence of Scottish Children, Univ. of Lond. Press.

[2] In children the intelligence quotient (or mental ratio) is the ratio of mental age to chronological age expressed as a percentage. A fictitious maximum of 14 to 16 years is assumed for the chronological age of adults.

children it has been estimated that not fewer than 1·5 and not more than 3 per cent. of Scottish children fall below the boundary line drawn at an intelligence quotient of 70. In the future, when intelligence tests have reached a much higher standard of perfection than they at present enjoy, it may be possible to state exactly what proportion of children are below or above any given limit of mental ability. Until this is so we shall not be able to determine precisely whether or not mental deficiency, in a strict sense, is increasing.

REASONS FOR SUSPECTING AN INCREASE

The evidence for the increase of mental deficiency in the community is partly inferential. The following line of argument is worthy of attention. If the members of a given population mate with one another at random with respect to any given hereditary quality, the proportion of individuals possessing this character remains constant from generation to generation. On the other hand, if mating does not take place at random, stable proportions of the different genetic types in the population will not be maintained. There is evidence that, in the human species, mating is not random where certain characters are concerned, but the degree of assortation has not been found to be great with regard to any character except intelligence. As pointed out in the Brock report (p. 41), persons of like intelligence tend to marry one another. Some of the statistics quoted in appendices support this view.[3] If mental ability were determined entirely by multiple hereditary factors, this kind of assortative mating would cause a continual increase of the more intelligent and less intelligent groups of the population at the expense of those in the middle. The report, moreover, contains an account of a survey, instigated by the joint committee, which records, among other things, the mental ability of the children born to mothers or fathers judged by local authorities (or their representatives) to be mentally defective. The figures show that about one-third[4] of such children, on reaching maturity, are judged to be defective (p. 66); this conclusion applies equally whether the parents were certifiable under the Education Acts or the Mental Deficiency Acts. Now, if the incidence of mental defect is something like 1 per cent. and if mentally defective persons mate at random, it is unlikely, on general principles, that as many as a third of their children will be defective; it can be shown algebraically[5] that the proportion should probably be nearer one-tenth. Thus the high proportion of defective children born to defective parents is evidence for supposing that such persons usually select, for their partners, individuals whose mentality is not much greater than their own. This argument can only apply to defectives who are intelligent enough to live in the general community, and the conclusion is offset to some extent by the fact that idiots and imbeciles hardly ever become parents. The effect of assortative mating would be enhanced if the feeble-minded were especially prolific, but, as the Brock report states, "the supposed abnormal fertility of defectives is . . . largely mythical." All these considerations give some grounds for supposing that mental defect in the community is slowly increasing.

ENVIRONMENTAL INFLUENCES

We have so far been assuming that mental ability is determined only by heredity. Since the hypothesis is a very rough approximation indeed, the conclusion is also approximate. Actually, mental defect has many different forms and adverse environmental influences enter into the causation in a large proportion of cases. In a comparatively small proportion of instances the causation can be looked upon, for practical purposes, as entirely due to environmental factors (p. 19).

Since we are considering what reasons there are for the belief that mental deficiency is increasing, we may ask, to what extent environmental influences can determine fluctuations in incidence? On this topic the Brock report has little to say. The application of the principles of mental and physical hygiene may be reasonably expected to raise the general level of mental as well as physical efficiency in the community. A few principles can be formulated concerning special clinical types. The treatment of acquired syphilis, for example, should have diminished the incidence of amentia due to congenital syphilis during the last 30 years. Unfortunately there are no available figures by which to check this suggestion. Similarly, improved obstetrical technique may have brought about a decrease in the incidence of amentia due to birth injury. The causation of the special type of amentia, known as mongolism, is still a subject of discussion, but there can be little doubt that the maternal age at the birth of the child is the most important factor. If there is a growing tendency for women to marry later in life than formerly, then an increase in the incidence of mongolism is to be definitely expected. Encephalitis lethargica is now known to be an important cause of mental retardation, but the disease was unknown (or unrecognised) 20 years ago.

There remains the interesting problem of the rare diseases associated with severe mental deficiency which are known to be inherited in a fairly simple manner. Amaurotic idiocy is a disease which behaves as a Mendelian recessive, and other forms of idiocy or imbecility due to recessive genes almost certainly exist (p. 13). Natural selection would eliminate such conditions as these very slowly from the community. We can argue, from the fact that these diseases continue to exist, that they are sustained by a mutation-rate adequate to keep their incidence approximately constant. At present little is known about the causes of mutation in general, still less about these circumstances as applied to man. Here are to be found some of the avenues for future research (p. 53).

---

[3] See tables at foot of p. 102 and top of p. 83, which show that the number of families where both parents are defective is greater than would be expected from a random assortment.

[4] A close scrutiny of the figures in the tables suggests that many of the families were selected on account of the presence of defective children and that mothers of the same grade who had no defective children were not adequately represented in the sample. But even if the proportion were no more than one-fifth this would not alter the argument.

[5] Assume that mental grade depends upon multiple Mendelian factors. By a theorem of Fisher's, used in analysing physical stature, it follows that mental grade behaves approximately like an intermediate Mendelian character and that the heterozygote, or carrier, is intermediate between the normal and homozygous types. Call B the gene responsible for mental deficiency. Then the genotype AA is normal and has I.Q. (say) 100. The heterozygous genotype AB is dull and has I.Q. (say) 80. The homozygous genotype BB is defective and has I.Q. (say) 60. In a system of random mating these types have frequencies of $(1 - x)^2$, $2x(1 - x)$ and x^2 respectively, where x^2 is the incidence of defectives in the general community. If x^2 is equal to one in a hundred, these frequencies are as 81 : 18 : 1. (All this applies just the same if B is a recessive gene—as some people believe it to be—and the carrier has I.Q. 100 instead of I.Q. 80.) A mentally defective person, mating at random, 81 times out of 100, will choose a normal mate and there will be no defective children. In 18 cases out of 100 a dull mate will be chosen and, here, half the children will be affected. Once in a hundred matings both parents will be defective and all the children will be affected.

Hence, out of every hundred children having a mentally defective parent $(0 \times 81) + (\frac{1}{2} \times 18) + (1 \times 1) = 10$ children will be affected. That is to say, if the incidence of mental defect is something like one per cent., and if mentally defective persons mate at random the proportion of defective children born to a defective parent should average about one-tenth.

THE LANCET

LONDON: SATURDAY, MAY 12, 1934

PATHOGENESIS OF MAMMARY CANCER

The experimental investigation of carcinogenesis in selectively bred strains of mice which is being carried out in the Institut du Radium in Paris is yielding results of exceptional interest. By selective breeding Mme. Dobrovadskaia-Zawadskaia had succeeded in establishing strains with a very high or very low incidence of spontaneous cancer of the mamma in the female mice. The males never develop mammary cancer, not even in the strains with a high incidence. Last year we drew attention [1] to a short communication by Dr. A. Lacassagne in which he recorded the remarkable observation that the repeated injections of a pure preparation of folliculin into young males belonging to a strain with a high incidence of mammary cancer was followed by the appearance of mammary cancer in these animals. The tumours were sometimes multiple and appeared at a relatively early age. No such effect was then observed either in the males or in the females belonging to strains with a low incidence. The work has been continued and Lacassagne now reports [2] the frequent appearance after repeated injections of folliculin of mammary cancer, from 50–80 per cent., in animals belonging to two strains which normally have an incidence of only 2 per cent. The tumours appeared, however, not as frequently and at a much higher age in these two strains, between the tenth and fifteenth months, while in the strain with a high incidence 80 per cent. of the animals, including the males, had developed cancer between the fourth and the sixth months. A physiological difference observed between a strain with a high and one with a low incidence of spontaneous mammary cancer is that the œstrous cycle is much more prolonged and more regular in the former than in the latter, that the injection of equal doses of folliculin produces a more rapid and more intense vaginal reaction in the former than in the latter, and that the mammary hyperplasia produced by repeated injections of equal doses of folliculin sets in sooner and is more massive in the former than in the latter, both in the males and in the females. In the strains with a particularly high incidence of spontaneous mammary cancer the mammary tissue is therefore particularly susceptible to the action of folliculin. It is this factor of susceptibility—not the disease cancer itself—which is inherited; and it is this factor of susceptibility which is responsible for the exceptionally high incidence of spontaneous mammary cancer in these strains. Dr. W. Cramer has pointed out [3] the importance of this factor of susceptibility in determining the incidence of cancer in man, but it must be borne in mind that while in man the total incidence of cancer is distributed over a number of organs, in mice it is focused mainly on one organ—viz., the mamma.

In response to the action of folliculin the mammary tissue undergoes hyperplasia corresponding to the hyperplasia induced in the skin of mice by some form of chronic irritation such as painting with tar or pure carcinogenic substances. A process of hyperplasia similar to that induced experimentally by the repeated injection of folliculin has also been found in the mammary gland of middle-aged and old mice in the course of their lives, as was shown 24 years ago by Dr. M. Haaland in the fourth scientific report of the Imperial Cancer Research Fund. His figures show hyperplastic nodules composed of acini containing collections of stagnant secretion, which sometimes leads to a distension into cystic spaces. Another relevant fact which may be recalled here is the observation of Prof. N. Goormaghtigh,[4] that the repeated injection into female mice of a preparation which he called folliculin, but which was probably less pure than that used by Lacassagne, produced a condition of the mamma closely resembling what is called in the human mammary gland the maladie de Reclus or Schimmelbusch's disease. Sir Lenthal Cheatle has drawn attention [5] to the fact that in women Schimmelbusch's disease is frequently followed by carcinoma. It is in fact a precancerous condition. We have here another example of the close similarity which exists between the pathogenesis of cancer in animals, whether spontaneous or induced experimentally, and in man.

The nature of the final step, the actual transformation of a normal cell into a malignant one, is as yet unknown. We do know however that this change occurs in one or several sharply circumscribed centres and not in all the cells of the mammary gland simultaneously. We also know from the work of E. L. Kennaway and F. W. Cook [6] that a close chemical relationship exists between certain carcinogenic substances—i.e., substances which produce cancer when applied repeatedly to the skin of mice—and to certain constituents and secretions of normal cells, especially œstrogenic substances. It is only a few years ago that a distinguished authority committed himself to the statement that cancer is a mystery the solution of which surpasses the wit of man. Such pessimism is out of date. Cancer will remain a mystery to those who look for a single factor as the cause of cancer: civilisation, diet, changes in hydrogen-ion concentration, cosmic rays, or what not. They ignore the mass of careful observations on animals and on man patiently collected during the last 30 years or more. But to those who take the trouble to inform themselves, these observations serve as a guide to an understanding of the disease as being the result of a multiplicity of causative factors acting successively and playing an essential part in bringing about the eventual transformation of a normal cell into a malignant one. We are entitled to assume that this final cellular change is essentially the same in whatever tissue it occurs. Only in this sense is it possible to speak of *the cause* of cancer and to admit that *the cause* of cancer is unknown. But the processes which lead up to this final stage may be different for each tissue and in this sense each tissue may be said to have its *causes* and its own specific pathogenesis.

THE ACTION OF LEAD ON THE KIDNEY

GENERALISED arterio-sclerosis is often seen in individuals who have long been exposed to lead, and chronic nephritis may also be observed. That these result from the action of lead cannot be proved, but their incidence in lead workers is high. Some have argued that such changes in the arteries and kidneys, occurring as they do in lead workers giving no history of attacks of colic or palsy, should not be attributed to lead but should be regarded as due to the same factors which cause decrescent arterio-sclerosis in persons not exposed to lead. Such reasoning is tantamount to demanding a history of delirium tremens in a chronic drinker before relating a cirrhosis of the liver to his alcoholism. Medical practitioners in Brisbane and other parts of Queensland have long held that chronic nephritis, terminating fatally in uræmia, is more prevalent in that part of Australia than it is in other parts of the world. In 1929 Dr. D. G. CROLL put this impression on a sound statistical basis by showing[1] from the death returns of the ten-year period 1917–26 that 1309 persons per 800,000 of the population died of chronic nephritis in Queensland before the age of 40, whereas in the other three States of the Commonwealth the number was 436, 421, and 418. A graph of the deaths in the various age-groups indicates clearly that a cause non-existent or non-operative in the other States was responsible for this strangely high mortality in Queensland, with its peak in the 20 to 29 age-group. It fell to Dr. L. J. J. NYE of Brisbane to relate this mortality to chronic plumbism in a work[2] which may be regarded as the most important contribution of Queensland to medical knowledge since T. L. BANCROFT discovered the adult filarial worm there 58 years ago.

Cases of wrist-drop and foot-drop were first described in Queensland children in 1892. In 1897 Mr. J. L. GIBSON began to come across weakness of the external recti combined with papillœdema, which he regarded as an early and therefore important sign of lead poisoning; in 15 years he saw 54 of such cases. In seeking a cause for the plumbism, NYE was led to examine closely the habits of the children. In Queensland houses are commonly built with verandas whose railings are of wood, which, especially in the neighbourhood of towns, are usually painted with white lead paint. In that semi-tropical climate the sun soon converts this paint into a powdery substance, which rubs off easily on the hands, and this has been found to be a soluble carbonate of lead. In the summer young children spend a large part of their time on the verandas, and the younger members of the families affected are generally in the habit of biting their nails or sucking their fingers. Among children a local pastime was discovered which consisted in licking the rain drops from the veranda railings. Quite recently Dr. S. F. MCDONALD, going over the same ground, accepted[3] the "paint-fingers-mouth" theory of causation as the best working hypothesis. As a rule, the patient first comes under medical observation early in adolescence, the history being that for years the child has not been as well as other children. In later stages this lassitude increases, and anæmia, vomiting, failing vision, and often epistaxis occur. Elevation of blood pressure is invariably present, and is accompanied by hypertrophy of the heart. Occasionally cerebral hæmorrhage resulting in hemiplegia has been observed. Retinal vascular changes, with engorgement of veins, hæmorrhages, exudate, and choked discs are commonly seen. Œdema is inconspicuous, and renal failure ending in uræmia is the usual conclusion.

A federal investigation published in 1932 upheld the contention that kidney disease in young people in Queensland is extraordinarily prevalent. It reached the tentative conclusion that the chronic nephritis common in Queensland arises, as elsewhere, as a result of many factors productive of kidney damage, including principally familial weakness of the kidney fabric, damage produced by congenital syphilis, and conditions set up as the result of the acute or prolonged action of toxins derived from pathogenic organisms. In Brisbane, in cases where such predispositions exist, the concurrent ingestion of infinitesimal doses of lead from an undetermined source appears in a proportion of cases to precipitate a fatal issue many years earlier than would otherwise be the case, weeding out the great mass of chronic nephritics before they attain the age of 40. Since whatever factor is operating in Brisbane appears to be operative also in several other cities of the Brisbane type, the possibility of lead poisoning being a factor in these areas, though it does not figure in hospital records, cannot be entirely discounted, but must be investigated before findings can be conclusive. The work on which these tentative findings are based is included in the full report submitted to the Director-General of Health in Canberra. NYE replied to the findings of the official inquiry by showing that after a careful review of the statistical, clinical, environmental, and experimental evidence which has been collected in the federal report and in his work, it must be admitted that lead poisoning in childhood is at least one factor which is responsible for the high rate of mortality from chronic nephritis in Queensland—a rate, however, which happily now shows some signs of abating. The amount of positive evidence incriminating lead paint is indeed so overwhelming that it seems almost perverse to insist on a further search for other causes before taking preventive measures against poisoning. NYE's work emphatically teaches the lesson of the damaging effects of lead on young tissue and strengthens the demand that lead in any form should be banished from places which serve as a playground for restless and meddlesome youth.

TUBERCULOUS EMPYEMA

ONE of the gravest complications of pulmonary tuberculosis is tuberculous empyema, but the outlook should not be regarded as hopeless even though secondary infection with pyogenic organisms has occurred. In some instances a pleural cavity previously full of tuberculous pus will remain dry after two or three simple aspirations or air replacements—a result as surprising as it is gratifying, for such exudate may be loaded with tubercle bacilli. In other instances pus containing pneumococci or other organisms in addition to tubercle bacilli may be sterilised by the injection of aniline dyes or replaced by gomenol oil or by a solution of gelatin containing euflavine as in the method advocated by Crocket. It is only when such methods as these fail, or when severe toxæmia proves that a pyothorax is of malignant type, that surgical intervention becomes necessary. The evacuation of pus, whether by closed or open drainage, is essential in such cases and the risks of further infection from without, of non-expansion of the lung, and of a permanent sinus must be incurred.

In a recent review[1] of the subject J. C. JONES and J. ALEXANDER describe the methods they have employed in the treatment of 70 consecutive cases, and their results are classified in four groups.

Group 1 consists of tuberculous empyema uncomplicated either by active tuberculous disease in the lungs or by the presence of secondary organisms. This, the most benign form, is unfortunately the least common. It usually yields to repeated aspirations which, needless to say, must be performed under strictly aseptic conditions.

Group 2 includes those cases of tuberculous empyema in which pyogenic infection has already occurred, but excludes those in which there is evidence of active tuberculous disease in the lungs. The object here is to evacuate the pus and to cause the lung to re-expand, and this may sometimes be accomplished by aspirations. Irrigations and the injection of antiseptics of the aniline group may assist in cleansing the pleural cavity. If these fail, closed or open drainage will be necessary, for if aspiration is frequently repeated sooner or later further infection will occur. Closed or open drainage should therefore be instituted as soon as it is evident that aspiration has failed. Phrenic avulsion by reducing its capacity will assist in the obliteration of the pleural cavity, but an extrapleural thoracoplasty is often necessary to complete its closure.

Group 3 includes tuberculous empyemata uncontaminated by secondary infection but associated with active tuberculous disease of the lungs. If simple aspiration with air replacement fails the physician finds himself on the horns of a dilemma. If he seeks to cure the pyothorax by bringing its walls into apposition, the ideal method in the treatment of all empyemata, he must either encourage expansion of a lung only recently collapsed as a therapeutic measure for the treatment of active disease, or he must bring the chest wall into contact with the collapsed lung. If there is still hope that the pulmonary disease may be arrested thoracoplasty is indicated, usually preceded by phrenicectomy. It is encouraging to note that of 21 such cases submitted to thoracoplasty 16 could be claimed as "cures," that is to say, obliteration of the empyema cavity was secured without the persistence of a sinus, while arrest of the pulmonary disease was indicated either by the absence of expectoration or of sputum containing tubercle bacilli.

Group 4 is composed of the gravest types of disease in which a secondarily infected tuberculous empyema is associated with active phthisis. An attempt may be made to sterilise the empyema by aspirations and irrigations, though it is only very rarely that this object is attained. Closed or open drainage is usually essential, and though re-expansion of a therapeutically collapsed lung may follow, such a result may even be desirable if the patient suffers from dyspnœa and if the contralateral lung is also the seat of tuberculous disease. In the rare instances in which the opposite lung remains healthy, drainage and irrigation may produce so great an improvement in the patient's general condition and so satisfactory a cleansing of the diseased pleura that a thoracoplasty may be undertaken with some hope of a successful result.

The authors maintain that the prevailing prejudice against operation in the treatment of tuberculous empyemata is not justified by their experience of the risks attaching to it. Though of the 70 patients 23 died only 6 deaths could be attributed to surgical interference, and the same number of deaths occurred among patients who had been treated by aspiration alone. Cures were attributed to thoracoplasty in 32 out of 43 cases so treated. Failures to secure the adequate drainage, upon the success of which the result of thoracoplasty at a later stage may depend, are often due to faulty technique. The drainage-tube may be inserted at too high a level, it may be too short or too long or too narrow, or its removal before the cavity is obliterated or thoracoplasty decided upon may lead to failure. A thoracoplasty may be too timidly undertaken or performed "in so few stages as to make the operative mortality frightfully high." On the other hand, it might be pointed out that there are limits to the endurance of patients, especially of patients whose morale has already been undermined by a lingering disease.

INTERNATIONAL MEDICINE

THE Milroy Lectures of the Royal College of Physicians of London are concluded this week; they have been expanded by the lecturer so as to bring the history up to date of international coöperation in public health, as represented by the general work of the health organisation of the League of Nations. Criticism of the League of Nations is common. The reasons why it has not done certain things which it has tried to do, as well as other things which it has never tried to do, are imperfectly understood, as is evident from everyday comment; but no one who has followed its work for international health can fail to see here much fine achievement. This is what we should expect, for the international nature of medicine is so clear to all that even the most ardent critic of the League of Nations, and indeed of any attempt at international understandings, will allow that coöperation to eradicate disease and to prevent its spread from one country to another is good for the world. Sir George Buchanan, a member since its foundation of the League of Nations Health Committee and our Government Representative at the Office International d'Hygiène publique, has been able in this series of lectures to tell a fine story of international endeavour.

ANNOTATIONS

A CLINICAL RESEARCH UNIT

A NEW departure in hospital practice is announced from the Middlesex Hospital, where a gift of £15,000 has been received from Mr. S. A. Courtauld to found a Clinical Research Unit. The unit will be under the direction of the medical school council, and its activities will be directed to the intensive investigation of selected diseases. Mr. Courtauld's generous and discriminating donation is the culmination of a magnificent series of gifts to the hospital and school, which he has already endowed with laboratory services fitting the institution to serve as a basis of this original and important departure. The unit will consist of small wards of 1 to 3 beds, in all 15 to 20 beds, and will be provided with clinical lecture theatre, test rooms, and offices, and be under the control of the heads of the Bland-Sutton institute of pathology, the Courtauld institute of biochemistry and the department of physiology, while the work throughout is to be conducted in collaboration with members of the staff as they happen to be particularly interested in any diseases or conditions upon which the investigations are being concentrated. A close link is thus forged between the hospital, the medical school, and the research laboratories, for the professorial staff will have direct contact with and share responsibility in the treatment of patients, the fruits of laboratory work being thus carried promptly into the wards. The relations between the clinical and academic staffs of the hospital will be strengthened. The patients, moreover, being in the care of the unit, will have the advantage of prolonged stay under treatment when it is found advisable; they will not lose by the compulsion that must exist in general wards to discharge patients at the earliest moment that they can be moved, their beds being urgently required. In particular those who are not responding to treatment will obtain the advantage of more specialised observation. This association of the medical school in the control over beds in the hospital, sharing in the ultimate responsibility of the Board for the patients, is almost a revolutionary departure, but it is one under which advantage should accrue to the patients concerned, to the students of the school, and, what is more important, to the development of medical science..

DIABETES IN CHILDREN

IT is still too soon to estimate the expectation of life in diabetics treated with insulin from childhood; but we can say at least that this disease has now become compatible not only with life but with normal development, growth, and activity. E. P. Joslin [1] has pointed out that whereas in pre-insulin days an elderly diabetic lived about five times as long as a diabetic child, the balance is now weighed in the other direction. Untreated, these children are quickly reduced to a state of cachexia and misery, and if they live sufficiently long are stunted and infantile; but with insulin and under suitable conditions they can hold their own with contemporaries and have every chance of attaining maturity and parenthood. This change in prognosis was considered in our columns on April 14th by Dr. R. D. Lawrence, and he showed that the result depends largely on the care with which treatment is carried out. Fortunately, however, habits are readily acquired by the young, and although strict dieting is never altogether simple, there is usually less alcoholic and dietetic excess to unlearn in childhood than in later life, while the relatively high carbohydrate diets now in vogue make the régime much less trying than formerly. The actual injection of insulin becomes with many children a routine which is hardly more irksome than cleaning the teeth or evacuating the bowels, and the measurement and administration of the drug can be undertaken by most normally intelligent children over ten. For those to whom the insertion of the needle remains a focal point of unhappiness, an ingenious automatic syringe has recently been devised by H. Busher [2]: the syringe, after being filled, is held under tension by a spring; the apparatus is "cocked," placed firmly against the skin, and released by touching a trigger; and the injection is thus effected, it is said, with great rapidity and a minimum of discomfort.

Granted ordinary care there remain various unavoidable complications—infections are far the most important—which may need special and efficient treatment if they are not to end with the patient in coma. In preventing such disasters it is obviously useful to have frequent blood-sugar and urinary examinations and trained assistance at the first evidence of ill-health; but Dr. Leslie Cole's paper, completed in our present issue, shows that good results can be got even in comparatively poor homes in an agricultural district, where hospital visits are infrequent and medical help is hard to come by. His case reports make very encouraging reading, since nearly all the children are within the ordinary limits of height and weight, show no limitation of physical or mental activity, and have developed normally, although in some of the older girls there has been amenorrhœa or irregular menstruation. When these things are possible under difficult conditions one cannot but feel that the outlook for the child with diabetes is really hopeful, and look forward to the time when something corresponding to insulin can be given without injection.

TRAUMATIC SHOCK

William Clowes in 1568 attributed the prostration following severe injury to the action of some noxious substance produced in the wounded area. A more complete knowledge of the anatomy of the circulatory and nervous systems led subsequent workers to seek an explanation in a derangement of one or both of these systems, but references to a toxic agent appear at intervals in the writings of the last four hundred years, and the toxic theory of shock did not reach its apogee until towards the end of the late war. Cannon and Bayliss [3] produced a state of traumatic shock in cats by subjecting one extremity to blows, when the blood pressure declined and in a brief space they died. As cause of death hæmorrhage could be excluded, for the weight of the damaged extremity showed that the local fluid loss was comparatively trivial. Section of the femoral and sciatic nerves or even of the spinal cord failed to prolong life, and it appeared, therefore, that a third factor must be concerned. It was known that injection of histamine—a substance which can be prepared from most animal tissues—causes a fall in blood pressure and death in the experimental animal, and Cannon and Bayliss came to the conclusion that this substance or some such product was absorbed from the traumatised area and was responsible for death. During the last ten years, however, much additional experimental work on these lines has been done in the United States and on the continent, and the toxic theory of shock has found few supporters. To A. Blalock, one of the most industrious investigators in this field, belongs the credit of having established the importance of fluid loss, not only in experiments of the Cannon and Bayliss type, but in trauma to the intestines and in experimental burns. He repeated the weighing experiments of Cannon and found that if a hindquarter amputation was done instead of a circular amputation of the limb a significant increase in weight could be demonstrated. In summarising his experimental[4] work he also gives an excellent résumé of the history of the subject and of its clinical aspects. He accepts the concept of primary and secondary shock, attributing the former to nervous inhibition and the latter to fluid loss into the traumatised area. Although no evidence of a toxin-formation has been discovered in any of his experiments, he retains this in his mind as a theoretical possibility. In discussing treatment he rightly emphasises the importance of preventive remedies such as warmth and an adequate supply of fluid. Experiment in what he terms "established" shock has been of little value. As he says in his concluding paragraph, there is at present no satisfactory treatment for shock which has persisted several hours.

THE EXTENSION OF LIFE

In a study of mortality in Great Britain and Sweden published in our issue of March 31st, the authors, Dr. Kermack, Colonel McKendrick, and Dr. McKinlay, found that the death-rates at ages have been declining in such a way as to suggest that the expectation of life is mainly determined by conditions obtaining during the child's earlier years. This raises the interesting problem (referred to in a leading article in the same issue) of how far it may be possible to predict future decreases of the death-rates at various ages, and thus calculate the real expectation of life of persons now living.

The extent to which life is likely to lengthen has recently been considered by Louis I. Dublin and A. J. Lotka in an inquiry into the history of longevity in the United States.[5] Large gains in longevity have, they show, been recorded in the last hundred years, and more particularly the last forty. The outlook for further improvement in the average length of life is, they think, entirely favourable, "since we have not yet fully availed ourselves of the knowledge which we now possess towards reducing mortality." To answer the speculative question of the ultimately attainable expectation of life, they have constructed a hypothetical life table, based fundamentally upon the New Zealand life table for females, 1931 (together with the experience of the Metropolitan Life Insurance Company among some of the more favoured classes of policyholders); for "it is surely reasonable to expect that what New Zealand is achieving at present we may hope to exceed in due course." On this basis they have assumed that ultimately the deaths in the first year of life may be reduced from the value of about 60 per 1000 which now prevails to the low level of 25. At age 1 they regard as possible a reduction of 10 per cent. from the mortality observed among females in New Zealand, 1931, while they adopt at older ages a slightly greater, and increasing, improvement, reaching 15 per cent. at age 21. They then assume that this reduction of 15 per cent. from the mortality of the New Zealand table is attainable for all succeeding ages up to 74, after which age considerably smaller improvements are predicted. Construction of a life table on this basis gives an expectation of life at birth of very nearly 70 years compared with 49 years in the United States life table of 1901 and with 60 years in the table of 1930. Comparison of the course through life of the populations in these three tables is of interest. The cohort of 100,000 persons born is reduced to three-quarters of its original number at age 24 in the 1901 table, age 49 in the 1930 table, and age 63 in the hypothetical table; one-half will remain at ages 58, 67, and 76, and one-quarter at ages 74, 78, and 83.

It might be maintained that the application of the New Zealand rates (still further reduced) to the population of the United States, with its large urban and industrialised areas, is too optimistic—that the Scottish authors are on safer ground in their observations of the past course of the death-rate and its regularity in the self-same area for which prediction is attempted. On the other hand, in the light of the experience among ordinary policyholders of the Metropolitan Life Insurance Company, Lotka and Dublin do not think that the values they have adopted for the United States are unduly favourable or incapable of eventual attainment. They see no reason why in the near future the "average" man should not be brought up to the level of the more favoured classes. If this optimism should prove well-founded the increasing proportion of old people in the community will have to be reckoned with more seriously in economic and social organisation. The coincidence of declining birth- and death-rates is shifting age-distribution to an extent that is not yet generally appreciated.

RETINAL ABIOTROPHY

The retina offers exceptional facilities for the study of developmental maladies, of which full use has been made. Some years ago the late Mr. Treacher Collins invited[1] his fellow ophthalmologists to regard retinitis pigmentosa not as the result of choroidal sclerosis but as an abiotrophy of the rods and cones with secondary involvement of the pigmentary epithelium. The term abiotrophy was introduced into general medicine by Gowers to connote the inherent low vitality of certain cells or systems of cells leading to early degeneration, and was lucidly explained by Mott in these words: "In contradistinction to normal senile decay are premature pathological processes of decay attacking groups, systems, or communities of neurons subserving special functions. . . . The neurons of a particular system die prematurely owing to an inherited or acquired want of durability. . . . ." The fact that retinitis pigmentosa is a familial disease in which heredity plays an important part is in favour of its being an inherited weakness innate in certain individuals and quite independent of inflammation or local vascular disease. Collins was able to show that advanced retinitis pigmentosa can exist without any serious involvement of the choroidal vessels. Mr. Arnold Sorsby has confirmed these findings and carried the conception of retinal abiotrophy further in a contribution to the recent ophthalmological congress. Another retinal disease which he finds best explained by the conception of abiotrophy is familial macular degeneration. Here the pigment is central, and day blindness, not night blindness, is the prominent symptom. It is suggested that whereas in retinitis pigmentosa the rods are first affected, in this other familial disease it is the macular cones that give way first. Collins called it "retinitis pigmentosa at the macula." It has been described as occurring at different periods of life in different families—congenital, juvenile, presenile. Some of these cases are purely retinal. Others are complicated by cerebral degeneration. In either case the onset of the condition in children previously healthy, its familial character, and its steady progress stamp it as an abiotrophic process. Little is known of the pathology of Leber's hereditary optic atrophy, but there is evidence that it commences as a primary degeneration affecting either the papillo-macular bundle or the ganglion cells of the macula. Its character as an hereditary disease suggests strongly that it belongs to the group of abiotrophies. Similar arguments are used by Mr. Sorsby to explain some rarer conditions such as the Tay-Sachs disease, which attacks infants of the Jewish race, and certain forms of choroidal atrophy. A schedule, reproduced in an earlier issue,[2] distinguishes between unassociated retinal abiotrophy and cases associated with disease of the brain as in the Tay-Sachs disease, or of the skin as in degeneration of the elastic fibres associated with angeoid streaks of the retina (Gronblad's syndrome), or of the skeleton as in an interesting family group discovered by himself. Here, mother and five out of seven children were affected; besides macular coloboma in both eyes, there were present absence of nails, especially on the index-fingers and big toes, stunting, and even absence of phalanges, and tendency to bifurcation of the terminal phalanges of the thumb and big toe. Retinitis pigmentosa itself is sometimes associated with incurable deafness or with mental defect, which, as Collins suggested, are probably also due to abiotrophy, which picks out tissues which have attained a high degree of specialisation.

BIOLOGY IN THE SCHOOL CURRICULUM

A HEADMASTER of the old type used to say that if a boy was aware that he had either a body or a soul there was something the matter with him. The inference he intended to convey was that the physical and spiritual needs of his pupils were so well satisfied that they could disregard them and concentrate on other things. A hungry child is likely to become preoccupied with the needs of his body to the exclusion of everything else, and a child living in a state of unsatisfied curiosity is in a comparable condition. Biology is still given a casual reception in many schools, being lumped into the despised society of drawing and handicrafts. Miss B. D. Tyrrell, writing in the March issue of *Health and Empire*, has described a biology syllabus which has been followed for the last eight years in the Darlington Training College, a secondary school of over 600 girls. Sex instruction as such has no place in the scheme, and reproduction is emphasised no more strongly than any other vital function. The intention is, of course, that the children should regard reproduction as a natural and inevitable function like breathing—an excellent principle, but one which sometimes does not work out in practice. Children rarely use their powers of deduction except under the influence of a hint, and they can listen intelligently to information about stamens and gynæceums without observing any relevance to human reproduction. The syllabus outlined by Miss Tyrrell, if it is followed, is explicit on this subject as on others. It is allowed that on the whole the best girls work at classics, and finish their study of biology before they have touched zoology at all. Moreover, as she admits, few examiners expect a candidate to have covered the whole syllabus, so that much depends on the personal bias of the teacher. Before the age of about thirteen the girls receive instruction in general experimental science and chemistry only. For a year, while in the lower Vth, they are taught botany for one hour and twenty minutes per week. At the end of the year those who go on the classical side, "picked people on the whole," never study biology again unless they return to the science side in the VIth form. The aim is "to lay foundations of biological science by emphasising (*a*) interdependence of form and function, and (*b*) adaptation of form (expressing that function) to environment and to seasonal change." The chances of doing this during one hour and twenty minutes a week in the course of a single school year seem rather remote, but even a smattering of botany is better than no biology at all. The girls who go on the science side naturally have a greater chance of grasping these principles; they attend demonstrations of animal structure as seen in amœbæ, earthworms, butterflies, fish, and amphibia; in the upper Vth they study the anatomy of birds and mammals, and follow a revision course which emphasises the essential resemblances between plant and animal life. During their post-matriculation year opportunities are given for free discussion of evolution and elementary genetics. The syllabus aims at giving the children a general idea of vital functions. We must wish here that the time allotted to this part of education was more generous. But, considering that many schools devote no time at all to biology, we must commend a restricted course.

VETERINARY SCIENCE AND JOHN HUNTER

THE name of John Hunter is as much revered in the veterinary branch of medicine as on the human side; for the part he played, as one of the original founders of the Royal Veterinary College, was the stepping-stone of the veterinary science of to-day. The subject was recently brought before the Hunterian Society by Sir Frederick Hobday, the present dean of the college, in an address illustrated by means of lantern and cinema, embodying details of what has happened in the Camden Town school between its commencement in 1791 and the erection of the present day modern buildings, some of which (operating theatres and hospital for small animals) are already completed. Prof. Hobday prefaced his address by a tribute to the help which was given by certain members of the medical profession, mentioning especially the names of John Hunter, Drs. Clive, Baillie, Cruikshank, Home, Cooper, and Wilson, who opened their classes to the veterinary students who entered for their courses of study at the new institution. He paid special tribute to the keen powers of observation which John Hunter showed when writing upon certain lamenesses and other ailments of the horse, and drew particular attention to the classical surgical gland and other transplantation experiments which have now passed into the category of everyday operations in the routine of the modern veterinary consultant. His attention had been given to such equine ailments as "roaring" (due to paralysis of the left vocal cord) and "broken wind" (asthma) which he accurately differentiated in regard to their respective sources of origin; and his "Essays and

---

[2] THE LANCET, April 21st, p. 849.

Observations." contain much which can be read with interest by those who see a future in the study of comparative medicine to-day. The lecturer, in conclusion, suggested the establishment of a branch of the Hunterian Society amongst the graduates and students of the Royal Veterinary College, stating that the veterinary profession owed a great deal to the memory of John Hunter "for the part he played in the start of its oldest veterinary college; and that, knowing the reputation he bore for thoroughness in all he did for the science he loved so well, it was a great calamity to our progress that he did not live at least some ten years longer."

In the remarks which followed the lecture, Dr. Bullock, the registrar and librarian of the Royal College of Veterinary Surgeons, gave interesting extracts from some unique books in the college library which bore tribute to John Hunter and the part he had played in the foundation of the veterinary profession.

AN EMPIRE DAY APPEAL

At the Mansion House meeting held in support of the British Empire Cancer Campaign on May 1st, the Duke of York who presided said the purpose of the meeting was to inaugurate an appeal on Empire Day, May 24th. He recalled the hope he had expressed ten years previously that the shadow of the great fear of cancer was slowly but surely lifting, although much remained to be done. The policy of the campaign all along had been not to husband its resources but to meet every reasonable call made upon it in aid of cancer research. Lord Horder, who proposed a vote of thanks, said he was sure that the solution of the problem of cancer would yield to careful observation and patient research. Sir Hilton Young remarked that cancer now took the second place in the list of fatal diseases and justified the campaign in its primary task of promoting and coördinating research on the causation of cancer. Prof. W. S. Lazarus-Barlow, vice-chairman of the investigation committee and chairman of the appeal committee, spoke of the change in the type of investigation during the 30 years in which he had been associated with cancer research; it must not be thought, he said, that the paths pursued for 30 years had proved fruitless. The extension of the criterion of success—namely, freedom from the disease—from three to ten years showed a sense of growing mastery over the enemy. The associations and affiliations of the campaign throughout the British Empire and its friendly relations with cancer research organisations abroad entitled the campaign to national and imperial support. It was announced that the King and Queen and other members of the Royal Family had sent donations to head the Empire Day list. In response to the Duke of York's words the appeal committee of the B.E.C.C. has arranged for appeals at 1000 centres on May 24th.

GASTROSCOPY

The flexible gastroscope which was recently described in these pages[1] has made its début in America, and E. B. Benedict has made a preliminary report[2] on its use in the Massachusetts General Hospital, where 75 gastroscopies have been smoothly carried out. The instrument is in routine employment in many German clinics, but little has yet been heard of it from other countries. The reason is probably a certain hesitation about its value in diagnosis. It is clear from the German experience that, in general, gastroscopy offers no advantage over radiography in the recognition of gastric ulcer and gastric carcinoma, and it is never likely to become as necessary as cystoscopy. On the other hand it enables inflammatory and atrophic changes in the gastric mucosa to be seen much more clearly than by even the best radiological technique, and chronic gastritis can therefore be defined with greater precision than heretofore. Since the pathogenesis of chronic gastritis may well be the key to the prevention of more serious conditions, a new method for its investigation is to be welcomed. Benedict's experience so far bears out the German claim that gastroscopy with the Wolf-Schindler flexible gastroscope is an "easy, harmless, and profitable procedure."

CHILD GUIDANCE IN AMERICA

Since 1922 when the Commonwealth Fund of New York first turned its attention to mental hygiene seven major child guidance clinics have been founded directly through its agency, and support has been given in this country (in the words of the fifteenth annual report) "to finance activities which are still too novel to command full support from the British public." The London Child Guidance Clinic, now in its fifth year, is still liberally supported by the Fund, although as a measure of economy the parent Institute for Child Guidance was closed last summer, after it had offered training during the six years of its existence to 32 psychiatrists, 15 psychologists, and 289 psychiatric social workers. It should be of interest to discover what form the child guidance movement is taking in the land of its origin, and in this we have the help of Dr. D. N. Hardcastle, who has reported[1] after spending three years studying clinics in America. The lines of approach and the goals of treatment he finds still in a state of flux, and wide variations in philosophy are evident; some clinics are content with a simple evaluation of their problems and are almost didactic in their therapy, others attempt to analyse all their material, whether parents or children. Asked "what is the potential position of the general medical practitioner with regard to the child guidance clinic, and can his services be utilised?" 10 out of 12 clinics referred to the general lack of psychiatric education, and the practitioner's inability to coöperate; 3 clinics thought that when adequately trained the practitioner should treat the bulk of the patients who now come to the clinic, and 2 considered that he could then coöperate in psychiatric treatment. Five replies reported close coöperation on the physical side only of the patient; only one speaks of all-round coöperation. Three clinics, however, enjoy the coöperation of children's specialists; one regards itself as in opposition to medical practice. To the question whether non-medical persons should be able to refer cases, 11 out of 12 clinics definitely said that they should; 2 of them refrained from treating cases so referred until the practitioner had been informed and his permission given. In another question Dr. Hardcastle embodied the criticism so often heard, that the child subjected to a team of people loses all chance of a personal psychiatric contact. Eight replies point out that the child has a much closer contact with the psychiatrist than he would have in any other form of medical treatment; the parents are not present, for they are seen by the psychiatric social worker. One detailed reply states that 55 per cent. of cases have dual attention, the psychiatrist treating the child and the social worker his environment; in 26 per cent. the social worker alone goes into the home and environmental conditions, and in 19 per cent. the psychiatrist works with the child direct. Another reply suggests that a child in a general hospital ward would come in contact with far more doctors and nurses than the two or three contacts it makes at the clinic; yet another cites the number of contacts which a child might make among police, probation officers, and others if it did not attend the clinic. On the subject of treatment, 10 clinics claim to use the technique which will best suit the child and to employ all available facilities to create a friendly feeling; full use is made of psycho-analytic knowledge, but analysis is not practised. One reply stresses the danger of the psycho-analytic approach and another says that a small group of selected children are undergoing analysis. This question was less productive of controversial thinking than any of the others; Dr. Hardcastle suggests as a reason for this that the technique of treatment is as yet little developed in the clinics. A postscript to the paper gives the views of the director of one of the clinics who read the replies. This psychiatrist claims that the progressive clinics have recently evolved a more flexible approach and a much freer attitude towards treatment, the responsibility for having it or not being put wherever possible on the parent.

TREATMENT OF SEXUAL OFFENDERS

THE problem of dealing adequately with persons who appear before the courts charged with sexual offences is as much a legal as a medical one. Mr. Claud Mullins, in a lecture before the Medico-Legal Society on April 26th, pointed out a few of the almost incredible anomalies in the law governing these offences. For instance, the exhibitionist must be dealt with under the Vagrants Act, 1824, along with persons who persistently tell fortunes and run away. Apart from the fact that he is more than a mere social nuisance and needs to be dealt with in a different manner, his offence may actually be much graver than other offences which happen to be regarded more severely. For instance, Mr. Mullins related two successive cases which he had tried on one day. In the first, an exhibitionist had shocked and insulted two small girls; in the second, two men were charged with gross indecency in a public convenience. Of the two offences the former seemed to be by far the more serious. Yet the second comes under the Criminal Law Amendment Act, 1885, and the offender must be committed for trial. The practical administration of the law was better than might have been expected. This particular exhibitionist, having 12 previous convictions, could be given six months, and a solution for the problem of the second case was provided by a convenient by-law of the London County Council imposing a fine of £5 or under for committing an act of indecency with another person.

As an example of the comparative severity with which the law visits various offences, Mr. Mullins remarked that stealing of any kind can be punished with five years' penal servitude, and if committed in a dwelling-house, with 14 years' penal servitude. Perjury is punishable with seven years' penal servitude. On the other hand, if a man detains a woman in a disorderly house against her will or commits an indecent assault upon a girl of 13, the maximum penalty is two years only. A woman who procures an abortion on herself may be sentenced to penal servitude for life, but the penalty for a man who has carnal knowledge of an idiot or a mental patient in hospital is only two years. The severity of the law towards what are known as unnatural offences is probably, he suggests, based on the religious horror which this conduct excited in the Middle Ages and which modern research has shown to be quite misplaced. The punishment is far greater than that awarded for incest, and juries, with a surer instinct for justice, have returned verdicts sometimes incomprehensibly favourable to the accused. Mr. Mullins is convinced that sexual offenders need something more than mere retributive punishment, but disbelieves in the customary dichotomy of punishment and treatment, holding that punishment is often a valuable therapeutic measure. In this opinion he is supported by such experienced psychiatrists as Dr. James Rees and Dr. J. A. Hadfield. Prison will, he thinks, remain indispensable for some offenders if only to prevent an outbreak of lynch law, though prison has not given encouraging results as shown by the figures for recurrence. He considers that an indeterminate sentence based on the progress of the offender in prison is more likely to produce good results than a sentence fixed by the court on unscientific grounds. As measures of reform he advocates that the large remand prisons should have medical psychologists on their staff, so that a report on the condition of an offender could be available between conviction and sentence; that the prison authorities should have a statutory right to report on any case between verdict and sentence whether the court desired a report or not; and that time should be given for inquiry and report in all cases before sentence is passed. Although flogging as a preliminary to and part of an extended period of training may possibly be defended, Mr. Mullins strongly condemns this punishment in conjunction with or as an alternative to imprisonment.

The only real solution of the problem will, he holds, be found in preventing the kind of people who become sexual offenders from ever being conceived. In addition, he suggests that the law should be altered to be less hard on abortion and homosexuality, and harder on the wanton spreading of venereal disease and the promiscuous begetting of children by delinquents and defectives.

AT a meeting of the Royal Society, on May 3rd, Prof. Otto Warburg was elected a foreign member. Prof. Warburg, whose work on cell metabolism won him the Nobel prize for medicine in 1931, is director of the Kaiser Wilhelm Institut für Zellphysiologie, at Dahlem, Berlin.

THE series of articles on Prognosis contributed by invitation will be resumed early in June, when publication of the five concluding lectures on the Preventive Aspects of Medicine at King's College has been completed.

ST. MARY'S HOSPITAL, PADDINGTON.—The Duke of York presided last week at a dinner in aid of the building fund of this hospital. A sum of £105,000 is to be raised for building a new nurses' home and a pay-block, and the Duke stated that an anonymous donor had undertaken to double every pound received up to £15,000. It was afterwards announced that the £15,000 had not only already been exceeded and the promised similar sum paid over, but that the anonymous benefactor had offered to double amounts received up to Christmas next to the extent of a further £25,000. The result would be that provided the stipulated sum was subscribed in full, the whole of the £105,000 would be available by the end of the year.

SPECIAL ARTICLES

MEDICINE AND THE LAW

Drunkenness as Defence to Charge of Arson

At Leeds assizes last week, when a man was being tried for setting fire to the furniture in his house, a defence of drunkenness for once succeeded. He pleaded that he was so "mad drunk" at the time as not to know the nature of his act. He had, he said, ordinarily been a total abstainer, but domestic irritations had caused him to break out. Mr. Justice Finlay gave the jury a characteristically careful and accurate explanation of the law and the accused was acquitted.

Normally, as is well known, voluntary drunkenness is no defence. The drinker, in Coke's quaint phrase, is *voluntarius dæmon*; he has no privilege by the surrender of his self-control; "what ill soever he doeth, his drunkenness doth aggravate it." There are, however, two aspects of intoxication of which the law takes a less unsympathetic notice. First, though drunkenness (like anger) is not an excuse for crime, it may sometimes affect the degree of guilt where a particular intention is essential to the commission of the crime. Just as circumstances of provocation may reduce murder to the lesser offence of manslaughter, so drunkenness may be taken into account in considering whether the accused formed a particular intent. Secondly, drunkenness, if it produces insanity, may be a successful defence, as the recent Leeds case shows. Here it will not be enough to show that the man's mind was affected by drink so that he more readily gave way to some violent passion; this will not rebut the ordinary presumption that everyone intends the natural consequences of his acts. To be a successful defence the drunkenness must be of such a degree as to cause incapacity of forming an intention to commit the particular crime. The locus classicus for the law is the decision of the Court of Criminal Appeal in Beard's case in 1920. There the accused had criminally assaulted a 13-year-old girl; in furtherance of the rape he placed his hand on her mouth and his thumb on her windpipe, thereby suffocating her. He was held guilty of murder in the absence of evidence of such a state of drunkenness as would negative the intent to commit the rape. The doctrine of criminal responsibility in relation to alcohol, it may be added, would apply equally if for alcoholic intoxication there were substituted mental or bodily conditions due to narcotic or stimulant drugs or their hypodermic injection.

Aplastic Anæmia: Inquest on Cellulose Sprayer

An inquest was held at Battersea last week upon the death of Charles Ingold, a cellulose sprayer's mate, aged 19, who was found to have died of aplastic anæmia. His mother said he was brought home from work on the Thursday before Easter with a temperature of 103°; there were mauve patches under his skin. He was taken to the St. James Hospital, Balham, and his two brothers gave blood transfusions, but he died on Easter Sunday. Dr. W. L. MacCormac, medical officer at the hospital, explained the effects of the disease at the inquest. On admission the young man's blood was found to have turned almost to water. Two days before death specimens of his blood showed only 100 white blood-cells as compared with the normal 6000. Ingold's employers, for whom he had worked since November, were represented at the inquest. Allusion was made to a secret formula used in the spray for lacquer work. It was admitted that one element in the formula was harmful, but it was claimed that ventilation made it normally innocuous. The air in the factory, it was said, was changed 40 times an hour though the Home Office suggested a minimum of 30 times. The formula was shown to the coroner (Dr. Edwin Smith) and to Sir Bernard Spilsbury who gave evidence. The latter observed that this was a rare occupational disease, possibly due to benzine poisoning; the cause of the disease was not established. Dr. Donald Hunter, research worker in anæmia at the London Hospital, stated that this form of degeneratory anæmia was often due to benzine poisoning in other countries, but in the United Kingdom, where factories were excellently ventilated, no such case due to benzine poisoning had come within his own experience. According to Dr. Hunter the cause of 95 per cent. of the cases of aplastic anæmia was unknown.

The formula was not disclosed. Had the coroner been satisfied by the technical evidence that the public interest required the full analysis and examination of what was claimed to be a trade secret, he would no doubt have insisted on public disclosure. It was agreed that the cellulose spray contained benzine. The normal ingredients of the lacquer employed in the factory were stated to be the same as those used elsewhere in other English factories of the kind; it was the solvent which was the secret.
